M. Vulpian, who was received with applause, said that he was proud of what he had done on the day he pronounced the words alluded to by M. Peter, and that he was prepared to repeat them to-day. Nothing could be grander from a humanitarian point of view than M. Pasteur's work, and it was a pity that M. Peter had chosen the hour when he was absent through illness to make his attack. "What can be M. Peter's object? Surely not to prove that the method had sometimes been unsuccessful. That has been admitted by M. Pasteur himself. M. Peter has accused M. Pasteur of concealing facts. This is untrue. In each of his statistics the rare failures have always been mentioned. M. Peter relies upon the statistics to show that the method is inefficacious; but all those who have examined them without bias have recognised that they afford a striking proof of the preservative value of the method. He endeavours also to show that the intensive method is dangerous. Stripping his language of all artifice, M. Peter in reality accuses M. Pasteur and all his assistants not only of a grave error, but even of involuntary homicide. His propositions may be formulated as follows: (1) M. Pasteur's anti-rabic method is dangerous, as it may communicate rabies to those who are so treated. (2) The method is inefficacious. To prove that the anti-rabic method is dangerous, M. Peter has brought forward a small number of cases where death, according to him, is attributable to what he terms the "collaboration" of the two viruses forming, to use his own expression, the canino-experimental virus. As regards the cases seen in England, the certificate of death of Wilde sent to M. Pasteur is formal, indicating pulmonary disease as the cause. The cause of death in the case of Smith is more obscure, but until Mr. Horsley's report is published it should not be brought into the discussion. In the observations that have been obtained at home (in France) M. Peter has noted the occurrence of general fatigue (*courbature*) in the patient as a proof that the *materies morbi* was derived from the rabbit. But where did M. Peter recognise this fatigue in rabbits? and by what feat of imagination can he see in the fatigue of the patient the proof of rabbit-derived infection? The pains at the seat of the inoculations have no diagnostic value. All sorts of sensations may occur after inoculation, and it is possible that, with the development of rabies, any existing wound may become painful. If we knew more about this disease—if, for instance, we knew for certain that rabies never occurred in a paralytic form in man—the paralytic symptoms adduced by M. Peter would have more importance. But this is not the case. Not only is it probable that the paralytic form of rabies will soon become a recognised variety, but it has even been described in a Paris thesis published before the application of M. Pasteur's intensive method, and consequently written without partiality. Van Swieten also quotes a case which occurred in 1684, and which is reported in the Philosophical Transactions by Dr. Roger Howman." M. Vulpian read several observations of the kind, and added that "we cannot, without committing a grave mistake, attribute the paralytic symptoms of rabies occurring in those who have been submitted to the intensive treatment to the effect of the rabbit virus. The rabbit-derived virus, indeed, does not always give rise to paralytic symptoms; in the dog so infected the rabies is of the furious kind. To return now to M. Peter's assertion that the method is inefficacious and irrational, having failed 'lamentably.' How can we lay down the law in such matters? This is not a question of theory, but of fact. M. Peter knows as well as anyone that the overwhelming proofs he speaks of do not exist. He bases his examination of the results upon an old statistical return of the number of deaths occurring annually in France from rabies, from which it would appear that, notwithstanding the preventive inoculations, the mortality remains the same. But these statistics are perfectly unreliable, and when quoted by M. Brouardel, the remark was added that the mortality was no doubt much greater than appeared. It has been pointed out repeatedly that fourteen cases have died after inoculation, and that sixteen deaths have occurred in individuals who have not undergone the preventive treatment. Adding the two together the mortality has been the same as the average—that is to say, thirty deaths in all, and it has been concluded by a comparison of the numbers of deaths that the chances were only as sixteen to fourteen in favour of the inoculated. But the truth is, the vast majority of those bitten have submitted to inoculation, and the *fourteen* deaths have occurred in 1726 cases, giving a mortality of less than 1 per cent., whereas the *sixteen* fatal terminations have occurred in a small minority, probably not more than a hundred cases, and give a mortality of 16 per cent., which is about the average mortality from rabies after dog-bite. Taking this figure, 16 per cent., as the basis of our calculation, of the 1726 persons treated, by M. Pasteur 276 would have died. Subtracting those who were not saved by his method, there remains 262 persons who owe their lives to M. Pasteur. And this is the lamentable failure of which M. Peter speaks! M. Peter's objections stand upon no solid foundation, and they are without value. The method of M. Pasteur is entirely free from danger, and nearly always preserves from rabies. It is successful even in an unhoped-for degree." M. Vulpian, whose speech was received with enthusiastic applause, was followed by M. Brouardel, who went over much the same ground. He read passages from the observations of Van Swieten, and quoted from the thesis of Dr. Roux to show that there was a paralytic form of rabies in man. He maintained also that there could be no question as to the value of inoculation as a criterion of rabies in obscure cases. M. Peter's attempt to discredit its certitude was useless, the results obtained by this means of investigation having been uniformly constant.

The *Semaine Médicale* of the 19th inst. publishes the account of a conversation on M. Peter's communication between M. von Frisch and its Vienna correspondent. Professor von Frisch says M. Peter is wrong in concluding that the cases he has brought forward died of rabbit-derived disease. The laboratory virus does not always give rise to a paralytic rabies, and the only proof that death had been caused by the inoculations would be the production of the dog, for whose bite the treatment had been undertaken, in a state of health. Since the publication of the results of his

Digitized by Google

first experiment M. von Frisch finds that "dogs which have been treated by the intensive method without previous infection with street-rabies have invariably succumbed."

The Pasteur Institute has lost nothing by M. Peter's contentions. The last three subscription lists have brought in 129,000 francs.

The following statistical account was distributed to the members of the Academy:—

General Statistical Account of French and Foreign Patients treated at the Pasteur Institute up to December 31st, 1886.

Persons bitten and treated	2682
Deaths	31
Mortality	1·15%

Persons bitten by animals known to have been rabid, either by experimental proof or veterinary observation:

Bitten	2164
Deaths	29
Mortality	1·34%

Persons bitten by animals suspected of rabies:

Bitten	518
Deaths	2
Mortality	0·38%

Statistics of French and Algerian Patients treated up to December 31st, 1886.

Persons bitten and treated	1929
Deaths	18
Mortality	0·93%

Persons bitten by animals known to have been rabid either by experimental proof or veterinary observation:

Bitten	1538
Deaths	19
Mortality	1·04%

Persons bitten by animals suspected of rabies:

Bitten	391
Deaths	2
Mortality	0·57%

Statistics of Bites about the Head and Face.

French and foreigners bitten and treated	214
Deaths	10
Mortality	4·66%

Persons bitten by animals known to have been rabid either by experimental proof or veterinary observation:

Bitten	186
Deaths	9
Mortality	4·83%

Persons bitten by animals suspected of rabies:

Bitten	28
Death	1
Mortality	3·57%

Comparison of the Simple and Intensive Treatments.

Bites about Head and Face.

Persons bitten by animals known to have been rabid either by experimental proof or veterinary observation:

French and foreigners bitten and treated	186
Simple treatment	136
Deaths	10
Mortality	6·66%
Intensive treatment	50
Deaths	0
Mortality	0

Statistics of Persons Bitten by Rabid Wolves.

Persons bitten	48
Deaths	7
Mortality	14%

Three of these deaths occurred during the treatment. They are, however, comprised in the return, and count in the percentage.

Persons who have Died after Treatment.

French.

Pelletier, Videau, Lagut, Bouvier, Clédière, Peytel, Leduc, Magneron, Astier, Moulis, Moermann, Clergeot, Jansen, Grand, Sodini, Leteng, Née, Gérard.

Note.—Pelletier and Moermann came for treatment thirty-five days after the bite.

Persons treated who have died of different Diseases.

Christin, meningitis (Dr. Genoud); Duresset, pulmonary disease (Dr. Yot); Rouyer, uræmia (report of Dr. Brouardel); Réveillac, unknown.

Note.—Goriot's case (a recent one) will figure in the 1887 statistics, death having occurred on January 16th.

Foreigners.

Ivanowa, Russian; Gagou, Roumanian; Zotoff, Russian; Nyasnikoff, Russian; Glutza, Roumanian; Lecudet, Dutch; Nikiforoff, Russian; Guardia Ribes, Spaniard; Pita, Spaniard; Requego, Spaniard; Berqui, Italian; Collinge, English; Smith, English.

Note.—Ivanowa was seized with symptoms six days after treatment; Gagou the day after the end of the treatment; Nikiforoff came a month after the bite; Requego thirty-four days after the bite. These count in the percentage.

Person treated dying of other Disease.

Wilde, Arthur, pulmonary disease (Dr. Foote).

FLORENCE.

(From our own Correspondent.)

FOR the present in Italy Florence is the centre of sanitary interest, owing to the charges brought against her salubrity by non-medical correspondents in influential journals. In the first quarter of 1886 there were, it seems, fifty-one deaths from typhoid and five from diphtheria; whereupon the foreign visitor was loudly warned to keep outside her gates until her municipality had purged her of the disease-producing causes. The Società d'Igiene, however, has just issued a report which proves Florence to have a lower death-rate than any other Italian town of approximate size; and that, as to typhoid, she ranks ninth among the thirteen great Italian cities in mortality from that disease. The document is a carefully compiled one, and is signed by the President of the Society, Dr. Paoli, by the two Vice-Presidents, Drs. Faralli and Fenzi, and by six other office-bearers, well known in the medico-statistical world. A few extracts may be useful to those of your readers who are asked (as is usual at this season) how far this or that Italian town is safe for the English sojourner.

In the quinquennium 1881-85 Florence had 811 deaths from typhoid, thus distributed: 202 deaths in 1881; 166 in 1882; 152 in 1883; 112 in 1884; and 179 in 1885. Except in 1885 there was thus in the preceding four years a progressive diminution. For the same quinquennium the mortality from every cause was 23·292, which (the typhoid deaths being 811) gives 34·8 victims to this disease per 1000. The population of Florence according to the census of 1881 being 169,001, there were in every 10,000 inhabitants 9·6 deaths from typhoid—i.e., less than one per 1000 yearly. In fact, the annual mean of deaths from this cause was 162—that is to say, 13·5 per month. It is therefore manifest that the mortality of the first quarter of 1886 ought to have been 40·5, but that it was 51 by one of those accidental variations common to every fact in nature, to be compensated by an opposite variation, as indeed happened in the quarter immediately following, when the mortality from the same cause was only 32.

Another point. That the importance attached to the deaths from typhoid is exaggerated is shown by the fact that in the necrological tables typhoid appears among the other causes of death as occupying only the eleventh place, the order of sequence being this:—1, pulmonary phthisis; 2, inflammation of the respiratory organs; 3, organic affections of the heart and great vessels; 4, marasmus and the varieties of tabes; 5, determinate causes and others; 6, cerebral apoplexy; 7, cancerous cachexia; 8, pulmonary catarrh; 9, enteritis and peritonitis; 10, meningitis and encephalitis; 11, typhoid fever. Moreover, it is necessary to distinguish, in the total number of deaths, those victims

Digitized by Google

who, having come to be cured in Florentine hospitals of diseases contracted in the outlying communes, have died in these hospitals. In the fifty-three months from July 1st, 1882, to Nov. 30th, 1886, out of 711 deaths from typhoid, 566 were of persons belonging to the commune of Florence, and 145 (rather more than one-fourth) were of the other category. With this legitimate deduction the deaths would be reduced to the much smaller mean of 128 per annum, and the mortality among the resident citizens would descend to 7·57 per 10,000 of the population yearly. Without this deduction, Florence still ranks only as ninth in mortality from typhoid, after Bari, Catania, Brescia, Leghorn, Palermo, Messina, Turin, and Milan; her death-rate from this cause being almost equalled by that of Naples, and slightly higher than that of Rome, Genoa, and Venice.

Yet another point. The observations on the mortality from typhoid made during the last six years have proved that there is no true centre of typhoid infection in Florence, the deaths having occurred in quarters of the city quite distinct and wide apart. With very few exceptions the malady has numbered its victims by preference, and almost exclusively among the very lowest in the social scale, who herd or huddle together in wretched habitations, whose life is a struggle with bad or insufficient food, foul air, scanty clothing, and neglect of every sanitary law. The Florence in which the English-speaking visitors congregate—the new Florence extending from the feet of the Colline di Majano, di San Domenico e del Pelegrino, up to the grand Viali, which separate it from the old city—offers hardly a case of typhoid to the statistician.

Finally, from the quite recent official publication of the Minister of Agriculture and Commerce it appears that at the end of 1885 the population of the Italian kingdom was 29,699,785, out of which in that year there were 737,217 deaths, which gives the proportion of 265·06 deaths per 10,000 of the inhabitants, or 26·50 per 1000. In Florence in the same year there were 4625 deaths, from which, deducting 720 as not belonging to the commune, there remain 3905. The population of the city up to that date being 173,063, the proportion of deaths that year was 225·64 per 10,000 inhabitants, or 22·36 per 1000—notably, therefore, lower than the general mean of the kingdom. To improve this state of things (relatively satisfactory as it is), the municipality will shortly put in practice new and extensive sanitary measures, chief among which is the daily flushing of the city drains, while the Società d'Igiene has appointed a commission, in concert with the great body of the practitioners, to examine the causes of typhoid at their source, and to aid the municipality in removing them.

Diphtheria, it is added, since the epidemic of fifteen years ago, has hardly been known in Florence.

Florence, Jan. 15th.

NEW YORK.

(From our own Correspondent.)

JOHN P. GRAY, M.D., LL.D.

THE death of Dr. Gray, superintendent of the New York State Lunatic Asylum, creates a vacancy among the alienists of this country which will not soon be filled. For over thirty years he stood in the front rank in his specialty. He made the asylum at Utica famous as a school in which were trained many of the more prominent asylum superintendents of this State. His own fame culminated in the trial of Guiteau, the assassin of President Garfield, when he appeared as the Government expert, and by his testimony as to the prisoner's sanity exercised so powerful an influence that prompt conviction followed. Dr. Gray was a man of massive physical as well as mental form and force, and while an autocrat in his field of labour, he was a most genial Christian gentleman, overflowing with sympathy for human suffering. Dr. G. Alder Blumer, the first assistant physician of the asylum, has been appointed Dr. Gray's successor. Dr. Blumer is of English birth, but was educated in this country, and has been on the staff of the asylum seven years.

QUARANTINE AT NEW YORK.

The quarantine of New York, always the most efficient in this country, has undergone marked improvements during the year. Detention as a quarantine measure has yielded to sanitary cleanliness and freedom from contagious diseases. So thoroughly has the health officer impressed upon the masters of vessels that cleanliness of their ships and healthiness of crew and passengers will be his test of their right to pass quarantine, that during the past year not a pound of cargo has been discharged in quarantine, nor has there been longer detention than was needful to make the necessary examinations. This is an entirely new experience in the management of quarantine with us, and is undoubtedly the beginning of a new era in the history of this old, cumbersome, and ineffectual method of preventing the introduction of foreign pestilences into our ports.

ABDOMINAL AND PELVIC SURGERY.

These new fields of operative surgery are being cultivated with an ardour among our surgeons quite astonishing. I have before me the cards of several hospitals announcing the operations in each on operating days. Abdominal section has the precedence. In one hospital four such operations are announced for one session. Cancer of the stomach, gall-stones, peritonitis, and uterine and ovarian affections are given as the objective points in the operations. Extirpation of the ovary for alleged hydro-, pyo-, or hæmato-salpinx is becoming alarmingly frequent. The question has been raised in the Academy, and none too soon. Is this operation required so frequently? One prominent gynæcologist stated in conversation that he had seen healthy ovaries that had been removed as in diseased conditions. The successful removal of a table-knife from the stomach by Dr. Bernays, of St. Louis, is one of the most recent achievements in abdominal surgery. The knife was nine inches and a quarter long, and lay transversely, the handle at the pylorus. The operator on exposing the stomach seized the handle, cut on it, and withdrew the knife; the patient did well. This is the second recorded operation for the removal of a table-knife from the stomach. The first was performed in 1791 by Schwabe, who extracted a knife six inches and a quarter long by the point; his patient recovered.

INTERNATIONAL MEDICAL CONGRESS: SECTION OF PSYCHOLOGY.

By the death of Dr. Gray this section was deprived of an energetic chairman, whose force and prestige would have ensured a successful session. His successor is Dr. J. B. Andrews, superintendent of the Buffalo Insane Asylum, New York State—a gentleman little less known as an alienist than his predecessor, and of equal force of character. He has begun the work of organisation with great energy, and will without doubt make the section one of the most interesting of the Congress. From present appearances the Congress will prove a great success. Every section is now well advanced in its preparation, and the profession of the States has become heartily and cordially enlisted in the work of organisation.

LABORATORY OF PRACTICAL HYGIENE.

Laboratories are increasing in this country. Several medical colleges have recently received endowments for departments for laboratory work. Recently the State Board of Health of Michigan petitioned the Regents of the University of that State to establish a Laboratory of Practical Hygiene, and the Regents have approved the suggestion, and will ask for the requisite appropriation.

January, 1887.

ROYAL COLLEGE OF PHYSICIANS.

AT the Comitia on the 27th inst., Sir W. Jenner, Bart., President, in the chair, the following gentlemen were admitted Members of the College:—Dr. G. A. Maconachie, Dr. J. A. Marston, Dr. Jas. Reid, and Dr. F. J. Smith.

A communication was read from the Royal College of Surgeons, with reference to the celebration of Her Majesty's Jubilee by the Colleges; and a Conjoint Committee was formed to consider the proposal.

Dr. Bristowe was nominated to the Committee of Delegates, in the place of Dr. Pye-Smith, resigned. Dr. Habershon, Sir Ed. Sieveking, Dr. Blandford, Dr. Sturges, and Dr. J. E. Morgan were elected to serve on the Council of the College.

The annual report of the Examiners was read, and a tabulated return showing the results of the several examinations was presented.

A report from the Committee of Management recom-

Digitized by Google

mending the appointments of Mr. F. G. Hallett as secretary, and Messrs. W. Fleming and C. E. Scragg as senior clerks to the Examination Hall, was adopted.

On the recommendation of the Council, the title of the Certificate in Hygiene was altered to that of "Diploma in Hygiene," and it was resolved that the College of Surgeons be invited to join in the examinations for this diploma.

On Dr. Quain's motion, the resolution adopted on June 29th with respect to the Croonian Trust was referred to the Special Committee, to ascertain what further steps were necessary to carry it into effect.

A report was read from the delegates appointed by the two Colleges to deliberate on the best use to which the unoccupied ground on the Thames Embankment, belonging to the two Colleges, can be applied. The recommendation of the delegates, that the ground be utilised for the prosecution of research in, and the exposition of, subjects connected with medical science, was adopted by the Colleges.

Obituary.

JOHN DENHAM, M.D., F.R.C.S.I.

ON Friday, the 21st inst., Dr. Denham died at his residence at Kingstown, near Dublin, at the advanced age of eighty-one years. Dr. Denham was well known in Dublin, where he practised for many years as an obstetric surgeon, filling for seven years the important post of Master of the Rotundo Lying-in Hospital in that city. The deceased was born at Killeshandra in 1806, and was the son of a Presbyterian clergyman. He was apprenticed to Dr. Ephraim McDowel, one of the founders of the Richmond Hospital, where he commenced his studies. He graduated in medicine at the University of Edinburgh in 1831, and the following year obtained the licence of the Royal College of Surgeons in Ireland. He was elected a Fellow of the College in 1863, some time afterwards a member of the Council, and president in 1873-4. He was also an ex-president of the Dublin Obstetrical Society. Dr. Denham's health became impaired a few years since, and he retired from practice; the occasion being taken advantage of by his friends, both lay and professional, to present him with a substantial testimonial in 1885. His contributions to obstetric medicine included "Case of Inversion of Uterus after Delivery," "Puerperal Tetanus," "Case of Labour with Unruptured Hymen," "Operations for Ruptured Perineum," &c. He was married twice, his second wife surviving him, and leaves a son, who is a member of the profession and practises in Dublin. His remains were interred in Mount Jerome Cemetery on the 25th inst., the funeral *cortège* being a very large one.

HENRY MUNROE, M.D.

DR. HENRY MUNROE, whose death recently occurred at his residence in Hull, was born in Kingston-upon-Hull in 1818. He received his professional education at Guy's Hospital, and became a Licentiate of the Apothecaries' Society in 1839, a Member of the Royal College of Surgeons of England in 1840, and in 1859 obtained the degree of M.D. at King's College, Aberdeen. In 1840 he settled in his native town, where he for many years enjoyed a large practice. Dr. Munroe was a Fellow of the Linnæan Society, and for a quarter of a century was lecturer on Medical Jurisprudence and Histology at the Hull and East-Riding School of Medicine. For some years he was an active member of the Hull Corporation, and rendered essential service to the town on the sanitary and other committees of that body. Dr. Munroe contributed several papers to the various medical and microscopical journals, and since 1860 he had been an active and ardent supporter of the temperance movement.

SURGEON JAMES PEDLOW, M.D. Q.U.I.,

SURGEON, ARMY MEDICAL STAFF.

SURGEON PEDLOW died of cholera on board the s.s. *Rangoon* on Oct. 21st, and was buried at Menbo. He was proceeding up the Irrawaddy to Bhamo in charge of C and D Sections, No. 16 Field Hospital. After leaving Thayetmyo he was attacked by cholera; all that could be done for him by careful attendance was afforded by Surgeon S. F. Freyer, A.M.S., who was with him till his death. Dr. Pedlow had seen much active service in Afghanistan and Egypt; for the former he was awarded a medal, and for the latter a medal and two clasps and bronze star, as mentioned in the despatches. He formerly served in the Turkish army and saw much fighting. He received a commission in the Turkish army, which was dated Feb. 3rd, 1878.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on Jan. 20th:

Balgarnie, Wilfred, Scarborough.
Beadle, Joseph, Middleton-in-Teesdale, Durham.
Brown, Lewis Henry, Cazenove-road, Stamford-hill.
Charles, Henry Evans, Swansea.
Farr, Joseph James William, Earls-court-road.
Frost, Francis Turner, College-road, Bromley.
Green, Robert Walter, Leeds.
Grose, John Sobey, Wadebridge, Cornwall.
Hebblethwaite, Harold, Bradford.
Hitchings, Robert, South Hackney.
Nicholson, Charles, York.
Powell, Lewis, Crouch End.
Rymer, James Francis, Pevensey, Croydon.
Simpson, Charles Shackleton, West Kensington.
Taylor, Frederick Howard, Fyrland-road.
Turtle, Frederick Wennan, Woodford, Essex.
Yunge-Bateman, Marcus George, Folkestone.

Admitted on the 21st inst.:—

Bidwell, Leonard Arthur, L.S.A., Lee-terrace, Blackheath.
Blenkinsop, Alfred Percy, L.R.C.P. Lond., Hilldrop-crescent.
Brook, W. H. Breffitt, Lincoln.
Bueno de Mesquito, Solomon, Goodmans-fields.
Corbin, Eustace Rhodes St. Clair, M.B. Lond., Stanhope-street.
Crouch, Charles Percival, Hampstead.
Garrould, Walter Robert, L.R.C.P. Lond., Willesden-park.
Gravely, Harry, L.S.A., Lewes, Sussex.
Hamilton, Robert Jessop, Princes-road, Liverpool.
Harris, Edward Bernard, L.S.A., Stoke Newington.
Helsham, Hugh Paul, L.R.C.P. Lond., Kirkdale, Sydenham.
Marshall, Arthur Lumsden, L.S.A., Leicester.
Staple, James Dibble, L.S.A., Bayswater.
Walsh, Robert William, L.S.A., Shadwell.
Walls, James, L.S.A., Handey, Wigan.
Williams, Arthur Henry, New Cross.

Admitted on the 24th inst.:—

Anderson, W. Maurice Abbot, M.B. Durh., Endsleigh-gardens.
Browne, Edward Granville, L.R.C.P. Lond., Bernard-street.
Brownfield, Harry Munyard, Rotherhithe.
Bullock, Roger, L.R.C.P. Lond., Warwick.
Cook, Edward Thomas, L.S.A., Southsea.
Dincker, William Rembold, L.R.C.P. Lond., Finsbury-park-road.
Evans, Howell Thomas, Tredegar.
Evelyn, William Arthur, L.R.C.P. Lond., Vincent-square.
Fitzgerald, Gerald Crowfoot, M.B. Camb., West Dulwich.
Ford, Theordore Albert Veres, L.S.A., Clifton, Bristol.
Greene, Henry Bertram Bladwell, Cheltenham.
Griffiths, William, L.S.A., Highgate.
Hamel, Julius, Clapham.
Hicks, Edward Harman, L.S.A., Folkestone.
Kitson, Francis Parsons, L.R.C.P. Lond., Martland-park-villas.
Loxton, William Arthur, L.R.C.P. Lond., Birmingham.
Taylor, John Francis, L.S.A., Blackheath.
McShane, George, L.R.C.P. Lond., Southsea.

The lectures for the present year will be commenced on Monday, the 31st inst, by John Bland Sutton, F.R.C.S. Eng. (Erasmus Wilson Lecturer), who will deliver on that day and on Wednesday and Friday three lectures on "Evolution in Pathology." The lectures will be commenced at 4 P.M. each day.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on the 20th inst.:—

Arnold, Francis Sorell, M.R.C.S., Bradmore-road, Oxford.
Blaker, Edward Spencer, M.R.C.S., Marmora-road, Honor Oak.
Braddon, William Leonard, M.R.C.S., Upton-upon-Severn.
Laker, Richard, L.R.C.P., M.R.C.S., Smith-square, Westminster.

GERMAN HOSPITAL.—The annual general court of governors of this institution was held on the 26th inst., when the report showed that the number of in-patients treated during the year was 1663, and of out-patients 23,219. The number of patients in the Convalescent Home was 449. The annual expenditure amounts to about £9200, while the reliable income is only £5800. The Duke of Cambridge, President of the hospital, has promised to preside at the 42nd anniversary festival, which will take place on April 27th.

Digitized by Google

THE Shrewsbury Hospital Sunday collection is to be held on the 13th prox. The last collection realised £238, an increase of £12 on the previous year.

AT the second annual meeting of the subscribers to the Sidmouth Cottage Hospital, which was recently held, a highly satisfactory financial report was presented.

THE first annual ball in aid of the funds of the Royal National Hospital for Consumption, which was recently held at Ventnor, proved highly successful.

MEDICAL MAGISTRATE.—The Lord Chancellor has, on the recommendation of the Lord-Lieutenant, placed the name of Dr. Langdon Down on the Commission of the Peace for the County of Middlesex.

ON the 19th inst. a cowkeeper at Leicester was sentenced to a month's imprisonment, without the option of a fine, for being the owner of meat intended for the food of man, but which was unfit for that purpose.

VACCINATION GRANT.—Mr. T. H. B. Rodwell, of the No. 2 district of the Loddon and Clavering Union, has received the Government grant for efficient vaccination (sixth time).

DEATHS OF CENTENARIANS.—The deaths are reported of a widow in Wetzlau, aged 108, and of the well-known sheikh of the howling dervishes in Constantinople, Alif Baba, aged 110.

A GRATEFUL PATIENT.—M. Ramon Fernandez, the Mexican Minister in Paris, has informed the Prefect of the Seine that a native of Zacatecas, a State of Mexico, has bequeathed £1060 to a Paris hospital where he was nursed in 1841.

AT the fortnightly meeting of the managers for the Central London School district on the 24th inst., it was reported that there had of late been an appreciable decrease of ophthalmia amongst the pauper children at the Hanwell schools.

THE report of the Charité Hospital in Berlin shows that 17,010 patients were admitted during the year 1886, to which number must be added 1253 infants born alive, also 79 stillborn. The total deaths amounted to 1904. The cases cured numbered 14,892.

PRESENTATION.—Mr. D. H. Thomas, Swansea, has been presented with an illuminated address and a purse of 160 guineas, in recognition of his services to the town and its inhabitants. The money has been given by the recipient to several local charitable institutions.

FOOD EXHIBITIONS.—An International Exhibition of Popular Food and Cookery will be opened at the end of the present month at Leipsic. The capital of 100,000 florins required for the organisation of an International Food Exhibition at Amsterdam has been subscribed.

FINSBURY DISPENSARY.—The annual general meeting of the governors of this institution was held on the 26th inst., when the committee's report showed that during the past year 15,912 new cases had been treated at the dispensary, with a total attendance of 35,366; 3151 patients had also been attended at their own homes.

WEST CORNWALL DISPENSARY AND INFIRMARY.—The fourteenth annual meeting of the supporters of this institution was held at Penzance on the 19th inst, when it was reported that the number of in-patients during the past year was 104, and of out-patients 1525. The income amounted to £635, and the expenditure to £624.

LINCOLN GENERAL DISPENSARY.—The annual general meeting of the governors of this institution was held on the 18th inst., when it was stated that the number of home patients treated during the year was 1513, and of out-patients 1744, making a total of 3257. The total income amounted to £886, and the expenditure to £833.

ADULTERATION OF FOOD IN SPAIN.—The Spanish Ministry of the Interior has issued a circular to the governors of the different provinces, calling their attention to the importance of food being sold in a pure and wholesome condition, and directing them to see that the various municipal authorities enforce the laws against all persons, of whatever position they may be, who adulterate food, and that their names and the nature of their offences are published in the *Boletin Oficial*.

LEEDS HOSPITAL FOR WOMEN AND CHILDREN.—The report which was read on the 24th inst. at the thirty-fourth annual meeting of the supporters of this hospital stated that the patients during 1886 had numbered 1339, 1140 being out-patients, and 199 in-patients. The total income was £2265, being £789 more than in 1885, and the expenditure amounted to £1382.

AT the meeting on the 26th inst. of the committee appointed to consider the proposal to found a medical school in connexion with the Dundee University College, the receipt of a donation of £6000 towards the foundation of the school was announced. This sum is in addition to the gift of £12,000 for the endowment of a chair of anatomy which had previously been announced.

STEPS are being taken by the officers and men of the Coldstream Guards to raise a monument to the memory of Sister Crump, one of the staff of nursing sisters doing duty at the regimental hospital, who recently died while in the actual discharge of her duty. Miss Crump joined the service four years ago, and after serving in Egypt since October, 1884, was invalided home last April.

VOLUNTEER MEDICAL STAFF CORPS.—Sir J. Hanbury, K.C.B., the principal medical officer of the home district, distributed on the 22nd inst. prizes to the Woolwich division of the Volunteer Medical Staff Corps, and took the opportunity of speaking strongly of the importance of a more extended system in connexion with the Volunteer force for tending the sick and wounded. An appeal was made to the medical profession to take up the matter.

NORWICH JENNY LIND HOSPITAL FOR CHILDREN.—The annual meeting of the governors of this institution was held on the 19th inst. The number of patients during 1886 was 1642, being 438 in excess of the number received in 1884, when the highest total since the establishment of the hospital was reached, and 50 in excess of 1885. The total receipts amounted to £2272, and the expenditure to about £1100.

CITY DISPENSARY.—The ninety-eighth annual meeting of the governors of this institution was held on the 20th inst. During the past year there has been a great increase in the number of personal attendances, the aggregate exceeding 30,000. The total number of patients treated was 15,124. The accounts showed that with a balance of £366 brought forward from last year the receipts had been £1744 and the expenditure £1443, leaving a balance or £301, but the liabilities at the present moment will absorb this. The annual festival in aid of the charity is to be held on the 24th prox.

HARROGATE BATH HOSPITAL.—At the general annual meeting of the governors of this institution on the 20th inst., it was reported that the number of patients treated during the past year was 664. This was a decrease on the previous year, but many cases recommended were of a convalescent nature, and consequently inadmissible; this difficulty will be removed when the convalescent wing is opened. The receipts amounted to £1535, as against £1636 in the preceding year. The number of baths administered was 5580, being 17 more than in the previous year.

BIRMINGHAM CHILDREN'S HOSPITAL.—The annual meeting of the governors of this institution was held on the 24th inst., when the secretary reported that the finances of the hospital were in a much sounder condition at the end than at the beginning of 1886, as the debt had been reduced to £301, whereas twelve months ago it was £910. The total expenditure during the year was £4306, being £142 less than in the preceding year. The number of in-patients was 794, out-patients 13,035, and 143 children were received at the Convalescent Home.

SOCIETY FOR THE PREVENTION OF HYDROPHOBIA AND REFORM OF THE DOG LAWS.—A most important meeting of this Society was held at the offices, 50, Leicester-square, London, W.C., on Monday. The Duke of Northumberland, the Duke of Westminster, the Earl of Egmont, Lord Stanley of Alderley, and Professor Huxley were elected vice-presidents, and several members were added to the general committee, among them being some well-known breeders and exhibitors of dogs. Proposals for future legislative action had been circulated among members, and these were considered and adopted formally as a basis for subsequent discussion. The Society aims at such amendment of

Digitized by Google

the Dog Act as will ensure, permanently, the better control of all dogs throughout the kingdom, and the removal of the large number of stray dogs, which are a constant source of danger and trouble; but, in consequence of the continued spread of rabies in the country, it is hoped that a short Act may be carried by Parliament for the extension to the provinces generally, for six months, of those regulations which have recently proved so effectual in London.

FOOTBALL FATALITY.—A boy aged nine years, residing with his parents at Irvine, died on the 20th inst. from injuries received while playing football at school. During a scrimmage he received a kick on the loins, which resulted in inflammation of the bowels. Deceased remained in an unconscious condition for several days after the occurrence.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—A festival will be held at the Holborn Restaurant on Wednesday, Feb. 9th, the Right Hon. Lord Halsbury (Lord High Chancellor) in the chair, to commemorate the opening of the National Hospital for the Paralysed and Epileptic, and with the especial object in view of assisting to raise a jubilee fund to enable the whole of the accommodation to be taken into use, wards containing fifty-five beds (of a total of 180) not having been as yet in occupation.

DORSET COUNTY HOSPITAL.—At the annual meeting of the friends and supporters of this institution, held on Thursday the 27th inst., an attempt was made by resolution to render members of the medical staff ineligible to sit on the general committee of the hospital. So great and effective, however, was the opposition to the motion, that it had to be withdrawn. The committee was enlarged from twelve elected members to eighteen, and a resolution proposed by Dr. Lush, that at least four days' notice be given of any notice of dismissal, was carried by a large majority.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of this Society was held on Jan. 12th, at the rooms of the Society, 53, Berners-street. In the unavoidable absence of the President, Sir J. Paget, the chair was taken by the Senior Vice-President present, Mr. Tegart. A sum of £1364 was voted for distribution among the 63 widows and 9 orphans on the funds. The expenses of the quarter amounted to £55 8*s.* 6*d.* One new member was elected, the resignations of 4 read, and the deaths of 5 reported. The secretary stated that during the last year there had been 16 deaths among the members, and 19 resignations, and only 5 elected. Astonishment was expressed by many of the directors that so few new members joined, the advantages being so great; some thought if it could be made more generally known that young men could join on completing their studies and when still living within the twenty-mile radius, and that, when once a member, the membership was not forfeited by removal beyond the radius or even out of the country, many young men would avail themselves of the opportunity of ensuring a slight provision for their widows and orphans.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ARNOLD, WILLIAM, M.R.C.S., L.S.A., has been appointed Medical Officer for the Blisworth District of the Towcester Union.

BEALEY, ADAM, M.A., M.D.Cantab., F.R.C.P.Lond., has been re-elected Honorary Consulting Officer to the Harrogate Bath Hospital.

BRITTON, THOMAS, M.D. St. And., M.R.C.S., has been re-elected Honorary Medical Officer to the Harrogate Bath Hospital.

COOMBE, ROBERT GORTON, jun., M.R.C.S., L.R.C.P.Ed., L.S.A., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births and Deaths to the Southminster District of the Maldon Union, vice Arthur Lattey, L.R.C.P.Lond., M.R.C.S., resigned.

DEANE, EDWARD, L.R.C.P., M.R.C.S., late Assistant House Surgeon, has been appointed House-Surgeon to the Royal Berks Hospital, vice G. A. Shackel, resigned.

DOYNE, R. W., M.R.C.S., L.S.A., has been appointed Surgeon to the Oxford Eye Hospital.

GAYE, H. S., M.D. St. And., M.R.C.S., has been elected Consulting-Surgeon to the Newton Cottage Hospital and Dispensary.

GREENE, GEORGE EDWARD JOSEPH, L.R.C.S.I., L.K.Q.C.P I., Admiralty Surgeon, Kilmore, has been appointed Medical Officer for Ferns Dispensary, Enniscorthy Union, vice Smyth, resigned.

HARSTON, LIONEL DE COURCY EAGLES, L.R.C.P., M.R.C.S., has been appointed Medical Officer to the Perth Hospital, West Australia.

HAYDON, EDGAR, M.B., C.M.Glas., has been elected Medical Director of the Newton Cottage Hospital and Dispensary.

HOBSON, M.D., B.S.Lond., F.R.C.S.Eng., has been re-elected Honorary Medical Officer to the Harrogate Bath Hospital.

LITTLE, A. N., M.R.C.S., L.S.A., has been appointed Third Assistant Medical Officer to the Worcester County and City Lunatic Asylum.

MACAULAY, THOMAS, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Market Harboro' Rural District.

MITCHELL, JOHN, M.D., C.M.Glas., has been re-elected Medical Officer to the Barnard Castle Dispensary.

MORRIS, EDWARD, M.R.C.S., L.S.A., has been appointed Medical Officer for the Fernhurst District of the Midhurst Union.

PATRICK, ROBERT, M.D.Dur., M.R.C.S., has been appointed Certifying Surgeon (under the Factories Act) to the Bolton District.

SCOTT, W. GIFFORD, M.B., C.M.Ed., has been elected Medical Director of the Newton Cottage Hospital and Dispensary.

SHAW, LAURISTON E., M.D., M.R.C.P., has been appointed Medical Registrar and Demonstrator of Practical Medicine to Guy's Hospital.

SOUTHERN, JOHN, M.R.C.S., L.S.A., has been appointed Medical Officer for the Ludlow District of the Ludlow Union.

TREDINNICK, ERNEST, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Stokesay District of the Ludlow Union.

WATSON, HARRY O., L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer for the Clee Hill District of the Ludlow Union.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, N.—Aural Surgeon.

HULL AND SCULCOATES DISPENSARY.—House-Surgeon. Salary £150 per annum, with house (unfurnished), coals, and gas.

LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant House-Surgeon. Board and lodging in lieu of salary.

LIVERPOOL NORTHERN HOSPITAL.—Assistant House-Surgeon. Salary £70 per annum, with residence and maintenance in the house.

NORFOLK AND NORWICH HOSPITAL, Norwich.—Assistant to House-Surgeon. Board, lodging, and washing provided, but no salary.

ST. BARTHOLOMEW'S HOSPITAL, Smithfield, E.C.—Assistant-Physician.

SHREWSBURY EYE, EAR, AND THROAT HOSPITAL.—Surgeon. An honorarium of £150 per annum will be given for three years.

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—On the 20th inst., at Clifton-gardens, W., the wife of G. D'Arcy Adams, M.D., of a son.

BALDING.—On the 24th inst., at Dane House, St. Albans, the widow of Mortimer Balding, M.D.Cantab. (who died on Nov. 23rd, 1886), of a son.

COMYN.—On the 18th inst., at Dawson-place, W., the wife of J. Sarsfield Comyn, Deputy Surgeon-General (prematurely), of a son.

HUNT.—On the 19th inst., at Crouch-street, Colchester, the wife of Edgar A. Hunt, M.R.C.S., L.R.C.P., L.S.A., of a daughter.

OMAN.—On the 13th inst., at Strada Mezzodi, Valetta, Malta, the wife of Neil Oman, M.D.Ed., of a daughter.

PAYNE.—On the 22nd inst., at Wimpole-street, the wife of Joseph Frank Payne, M.D., of a daughter.

STRUGNELL.—On the 24th inst., at Highgate-road, N.W., the wife of F. W. Strugnell, L.R.C.P., M.R.C.S., of a daughter.

MARRIAGES.

PRAIN—THOMSON.—On the 24th inst., at Calcutta, David Prain, Surgeon, I.M.S., to Margaret, second daughter of the Rev. W. Thomson, M.A., Minister of Belhelvie, E.B.

RELTON—BELL.—On the 25th inst., at the Parish Church, Ealing, W., Bernard Relton, M.R.C.S., L.S.A., to Georgina Kate, younger daughter of the late A. D. M. Bell, Esq., of Quebec.

SIMON—WILLANS.—On the 26th inst., at Christ Church, Lancaster-gate, by the Rev. Canon Fleming, B.D., assisted by the Rev. F. C. Cursham, M.A., Vicar of Cropwell Butler, Notts, Robert M. Simon, M.B., M.R.C.P., of 26, Clarendon-road, Edgbaston, Birmingham, to Emily Maud, younger daughter of William Henry Willans, of 23, Holland-park, Kensington, and High Clyffe, Seaton, Devon, Esq. (no cards).

DEATHS.

BROWN.—On the 20th inst., at his residence, 25, Dublin-street, Edinburgh, William Brown, F.R.C.S.Ed., aged 90.

CHESSALL.—On the 19th inst., at his residence, Horley, Surrey, William Chessall, M.D., aged 56.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, January 31.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Dr. J. L. W. Thudichum: The Diseases of Plants, with special regard to Agriculture and Forestry (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. J. Langdon Down: On some of the Mental Affections of Childhood and Youth (Lettsomian Lecture).

Tuesday, February 1.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Mondays and Thursdays, 9.30 A.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Respiration.
SOCIETY OF ARTS.—8 P.M. Mr. T. Armstrong: The Condition of Applied Art in England, and the Education of the Art Workman.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Bland Sutton: Genito-urinary Diseases of Animals.—Mr. D'Arcy Power: A Neglected Point in the Pathology of Colles' Fracture.—Dr. Griffith: Extra-uterine Fœtation.—Mr. Bruce Clarke: Subperitoneal Rupture of Bladder.—Dr. Barling: Tubercular Tumour of Brain.—Mr. Bilton Pollard: Multiple Perforative Necrosis of Skull of Tubercular Origin.—Dr. W. Edmunds: Horny Growth on the Hand.

Wednesday, February 2.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Dr. Gibbons: Case of Unilateral Galactorrhœa. Annual Meeting—Election of Officers and Council. The President (Dr. Potter) will deliver the Annual Address.
SOCIETY OF ARTS.—8 P.M. Dr. Alfred Carpenter: Sewage Irrigation.

Thursday, February 3.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. A. W. Rücker: Molecular Forces.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. G. Buckston Browne: The Position and Value of the Operation of Internal Urethrotomy.—Sir W. Mac Cormac: The Supra-Pubic Operation in its application to Stone in Children.

Friday, February 4.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Living Specimens:—Mr. Keetley: (1) A case of Arterio-venous Aneurysm of Cavernous Sinus (?) after Treatment by Compression; (2) A case of Cholecystotomy. Card Specimens:—Mr. H. Percy Dunn: (1) A Large Intussusception from a Child; (2) Tuberculosis of the Spleen from a Child of three months; (3) Extensive Rupture of the Duodenum following a Kick from a Horse. Papers:—Dr. Thudichum: On the Nature and Operative Treatment of Hypertrophies and Tumours of the Nasal and Pharyngeal Cavity.—Dr. Campbell Pope (for Dr. Suckling): A case of Acute Multiple Neuritis following Diphtheria, and one of Unilateral Progressive Facial Atrophy.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Mr. Edwin Freshfield: Some Unpublished Records of the City of London.

Saturday, February 5.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Carl Armbruster: Modern Composers of Classical Song—Johannes Brahms (with Vocal Illustrations).

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

A FACT IN FRENCH COUNTRY PRACTICE.

A FRENCH doctor being asked by a man one day to go to a distance to see his sick child, replied that it was too far to walk, and that he had no carriage. "Oh," said the man, "that doesn't matter; I am a livery stable keeper, and will drive you." Some time afterwards the doctor's bill was asked for. It was five francs. The livery stable keeper then presented his bill for the hire of the carriage. It was six francs;

Spero.—The Apothecaries' Society *does* labour under the disability described by its clerk, and this can only be remedied by an Act of Parliament, which we fear could not be obtained.

A Non-subscriber.—We regret that our correspondent should think it necessary to punish himself in the manner he proposes.

FISSURED LIP.

To the Editors of THE LANCET.

SIRS,—Your correspondent, "Fidelis," may be interested in a case of fissured lip under my care some three years ago.

I painted the adjacent surfaces with a 5 per cent. solution of cocaine, incised the base of the fissure freely, inserted a harelip pin and silk binding, covering the whole with collodion. The pin was removed about the fourth day, and the crack has never recurred. The patient was a woman of about twenty, much exposed to wind and weather, and the fissure had been in existence for three or four years. Ointments, strapping, collodion, simple incision, &c. had previously been tried in vain.

I am, Sirs, yours truly,
Jan. 24th, 1887. FISSURE.

To the Editors of THE LANCET.

SIRS,—If your correspondent, "Fidelis," will apply a piece of court plaster (which has been made thoroughly pliant by dipping it in hot water) over the fissure, the sides of it being pressed together, he will find that it will quickly heal. Salves or ointments would be of more avail as preventive than as curative treatment.

I am, Sirs, yours faithfully,
Jan. 24th, 1887. G. H. S.

To the Editors of THE LANCET.

SIRS,—I would recommend your correspondent, "Fidelis," to try the application of nitrate of silver in stick. I have seen a troublesome central fissure of the lower lip cured by its use after other applications had been tried without success.

I am, Sirs, yours faithfully,
Jan. 25th, 1887 B. H.

Digitized by Google

THE VALUE OF THE RUPEE.

Q.—The subject of the depreciated value of the rupee as affecting the pay of medical officers in India is a large financial question scarcely suitable for discussion in our pages. There can be no doubt that a great injustice is inflicted not only upon medical but upon all officers—civil and military—in India, by their pay being issued to them in rupees calculated at the value of 2*s.*, while in the ordinary transactions of trade the real value is something under 1*s.* 6*d.* In fact, officers receive only 75 per cent. of the pay which is professedly secured to them by regulation. We cannot doubt that some new arrangement will have to be adopted ultimately to remove these complaints; but we are bound to say that it is a large and very difficult subject.

Insects.—There is no doubt the lice may be contracted from clothing, linen, bedding, &c. The crab louse lays from ten to fifteen eggs, and the young are hatched in six or seven days, and become capable of reproduction in two weeks.

M. W. S.—With few exceptions the surgeon has all his meals in the saloon with the passengers, even where the officers dine by themselves; but he does not have a cabin in the saloon, nor does he sleep there.

Dr. Hawkes.—Yes.

"HOMŒOPATHY."

To the Editors of THE LANCET.

SIRS,—I know not who the "Baffled Inquirer" is, nor am I at present connected with the London Homœopathic Hospital; but I know that now, as ever, the medical officers of that institution are always happy to welcome and assist any inquirer who presents himself at the hospital and conforms to its established customs. Your correspondent says he made "repeated requests to be permitted to attend in the morning and assist in taking notes and examining the patients," but that he was not allowed to do so. I imagine he would not be allowed to do this in any other hospital in London in his character of an inquiring visitor. The case might be different if he were a regular pupil. Of course, all your readers will see the unreasonableness of his request to visit and examine the patients at his own convenience; for if he were allowed to do this, why not others? And how would it fare with the patients suffering from serious acute diseases to be examined and disturbed several times a day by sceptical, or even by unprejudiced, inquirers? Nothing of the sort would be permitted in other hospitals. Why, then, should your correspondent think that it would be allowed in the Homœopathic Hospital? I imagine that his memory is not very good as regards the points of therapeutics he incidentally mentions. As he forgets the drug that he was told had cured some cases of ovarian tumour, probably he is wrong in supposing that he was told that impetigo was cured by a solution of carbon, and that relapsing fever was best treated by natrium muriaticum. He could hardly have been informed at the British Homœopathic Society that all homœopaths studied their treatment in "Jahr's Materia Medica." If the "Baffled Inquirer" really wishes to inquire into homœopathy, I would recommend him to study it in such works as Dr. R. Hughes's "Pharmacodynamics" and "Therapeutics," where he will find something better than the "absurdities" which I quite believe he found in "Jahr."

As regards your own question, "Is there any other instance of all the scientific men in Europe resisting a true discovery for nearly a hundred years?" I would only remark that homœopathy is acknowledged as the truth in therapeutics, and is practised at the present moment, by upwards of 10,000 regularly educated and qualified medical men, some of whom may no doubt be considered to be "scientific men"; that it has hospitals in many European countries, and upwards of forty hospitals and lunatic asylums in the United States; that though there is only one chair of homœopathy in European Universities—viz., that at Pesth—it has colleges and universities in the less tradition-bound United States. On the whole, though we regret the attitude of the authorities of established medicine in this and other countries towards homœopathy, we make no "admission of despair and almost of failure" as regards the progress of Hahnemann's discovery. I am, Sirs, your obedient servant,

London, January 22nd, 1886. R. E. DUDGEON.

To the Editors of THE LANCET.

SIRS,—Many thanks for your kindly-expressed notice of my letter *in re* Homœopathy. Your readers might perhaps imagine that I was a "homœopath," but such is not the case. I am only a "puzzled inquirer," and my puzzle is not solved when I study Dr. L. Brunton's work—a text-book in almost general use; as in it I find drugs such as pulsatilla, bryonia, ruta, thuja, cantharis, and dulcamara—all recommended in small doses for various diseases! All these drugs I was brought up to believe were strictly homœopathic, but when I find them in such a work as the one mentioned I begin to wonder if there be not some mistake.

I am, Sirs, yours faithfully,

Longridge-road, S.W., January, 1887. A. G. BATEMAN.

*** Dr. Brunton and Mr. Bateman are, of course, free to use any drug they please. It is not the use of any particular drugs that constitutes homœopathy, and that has caused it to be contemned by the medical profession.—ED. L.

Invenis.—Parkes' Hygiene, Ganot's Physics, Baldwin Latham's Sanitary Engineering, and the Public Health Acts.

THE COST OF A HOSPITAL BED.

THE following statement of the comparative cost per occupied bed in the year 1885 in thirteen large general hospitals in industrial centres has been drawn up at Newcastle-on-Tyne:—Birmingham General, 237 beds, £56 6*s.*; Bradford, 113.6 beds, £53; Edinburgh Royal, 595 beds, £58 5*s.* 9*d.*; Glasgow Western, 368 beds, £50 18*s.*; Hull, 96 beds £65 16*s.* 4*d.*; Leeds, 253 beds, £56 7*s.* 9*d.*; Liverpool Southern, 161 beds, £40 0*s.* 6*d.*; London Hospital, 620 beds, £68 5*s.* 10*d.*; Manchester Royal, 253 beds, £60 1*s.*; Nottingham, 138 beds, £55 3*s.* 8*d.*; Sunderland, 128 beds, £42 3*s.* 9*d.*; Wolverhampton, 200 beds, £52 5*s.* 2*d.*; Newcastle Infirmary, 235 beds, £50 14*s.* 9*d.* Such comparisons are, however, fallacious and unreliable without a full knowledge of the dietary of the patients of each hospital, and other matters which contribute directly to increase or diminish the average cost per bed. For instance, in some hospitals the patients must provide at their own cost tea, sugar, and butter. This is the case, we believe, at Newcastle and the Birmingham General Infirmary; whereas at the Leeds Infirmary the patients are provided with everything. In this institution the average cost per occupied bed, in 1885, for these three articles of diet was £3 10*s.* 3½*d.*, which reduces the cost of the beds to £52 17*s.* 5½*d.* if calculated on the same basis of the other two hospitals named. At Leeds, again, the repairs of buildings and fittings are charged to the cost of in-patients; some other hospitals do not adopt this plan.

N. Y. Z.—Our correspondent should have been communicated with; but he does not allege that the gentleman who certified is unregistered. He would have real ground for complaint if an unregistered member of the staff had officiated.

Young Practitioner is referred to THE LANCET of Aug. 8th, 1885, p. 276, for an answer to his question.

W. G.—No.

THE GREAT NORTHERN CENTRAL HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Whilst tendering to you the best thanks of all those who have the welfare of this hospital at heart for so kindly calling the attention of your readers to its pressing wants, you will allow me to point out two important mistakes in your statement concerning the financial report submitted to the half-yearly meeting of the general council on the 14th inst., which, if not corrected, may prove detrimental to the success of the appeal for the required funds.

The cost of the block of buildings which the committee have determined to proceed with in the first place, and which will contain sixty beds, and part of the administration block, is *£20,000*, not £2000; and the amount required to complete the new hospital of 150 beds with a large out-patient department, is *£45,000*, and not £24,500 as stated in your paragraph.

I am, Sirs, your obedient servant,

Jan. 24th, 1887. WILLIAM T. GRANT, Secretary.

ARE MIDWIVES APOTHECARIES?

THE following may raise a question in the minds of the Apothecaries' Society, as it certainly will in the minds of their licentiates:—"Mrs. C. H. Botham, midwife, 69, Langdon-road. Mixture: One tablespoonful three times a day." Though a midwife may attend a midwifery case, does it follow that she may attend and supply medicines to patients? May she even do so in a case of puerperal fever or puerperal convulsions, and be within the bounds of her duty? We trow not.

Messrs. Krohne and Sesemann.—The name was given simply as that of the apparatus which was preferred by the writer of the article. There was no question of priority raised.

G. P.—We must refer our correspondent to our advertising columns for the information he desires.

OBSTINATE CONSTIPATION IN AN INFANT.

To the Editors of THE LANCET.

SIRS,—I shall be glad to have some suggestions from your readers regarding the management of a case of most obstinate and persistent constipation in a child of twelve months.

For a long time the bowels have not been moved without aperients of rather strong character, or the use of enemata of various kinds. The fæcal mass is often so hard and lumpy as to require being scooped out of the rectum. There is bleeding on almost every occasion of defecation. The child is artificially fed, and every kind of food suitable for a child of such a tender age has been tried without avail, and various constitutional remedies likely to be of service have also failed. There is no abnormal distension of the stomach or large intestine, and the child is well nourished. Indeed, it is rather above the average size, and is a fine, healthy-looking child. I am, Sirs, yours truly,

Jan. 18th, 1887. O. P. Q.

F.—1 and 2. These questions must obviously be answered in the affirmative.—3. Dr. Hack Tuke's work on the Influence of the Mind on the Body in Health and Disease.

C.—Yes, shortly.

Digitized by Google

THE VALUE OF NEVA WATER AS MEDICINE.

A CERTAIN baron in St. Petersburg has been for a long time selling a specific for a number of diseases at a high price. This has lately been analysed by order of the Medical Council, with the result that it has been declared to be nothing more or less than simple Neva water! It might have been expected that the publication of this fact would have seriously interfered with the baron's trade; but the Neva water remedy seems to have taken such a hold on the imaginations of the St. Petersburg public that they still flock to purchase it at from one to four shillings a bottle.

Mr. K. Taylor.—Tempora mutantur. Circumstances are now very different from those which obtained years ago, when the words quoted were written.

W. W. W. should consult a surgeon. We do not give advice.

N. has not enclosed his card.

THE BINIODIDE OF MERCURY AS AN EMMENAGOGUE.

To the Editors of THE LANCET.

SIRS,—I find the red iodide of mercury is a certain and safe emmenagogue. My attention was directed to its virtues quite accidentally some three or four years ago, since which time I have used it successfully in a large number of cases. I prescribe it in the form of mixture as follows; but I should think it would act quite as effectually in pills of a quarter of a grain twice a day, or an eighth four times a day:—℞. Sol. hydrarg. bichlor., ℥i.; potass. iodid., ʒss.; ferri ammon. citrat., ʒi.; ether. chlorici, ℥ij.; aquam ad ℥viii. One tablespoonful three times a day after meals. I am, Sirs, your obedient servant,

Jan. 24th, 1887. C. R. ILLINGWORTH, M.D.

THE CLIMATE OF PLYMOUTH.

DR. BAMPTON sends us word that he has seen primroses in bloom growing in the open at Plymouth during the last week. Under the circumstances, a primrose is a primrose and something more. It is a floral record of the current atmospheric conditions, and sums up or registers all the past meteorological and geological conditions to which it has been exposed. In short, it indicates the mildness and geniality of the climate during the late winter months. It is to be borne in mind that the people in towns farther north are exposed to more than the equivalent of South Devon rain, in the form of hail, snow, and sleet.

Alfred Robinson, M.B., M.R.C.S.—A chapter in Powell's Diseases of the Lungs.

M.D.—We fear little can be done in the matter.

Dr. Percy Boulton is thanked.

ERRATUM.—In a paragraph headed "Presentations," which appeared in our last issue, page 200, Mr. Foulston was spoken of as taking his departure *for* Earlstown, whereas, in fact, he is leaving that town for Liverpool.

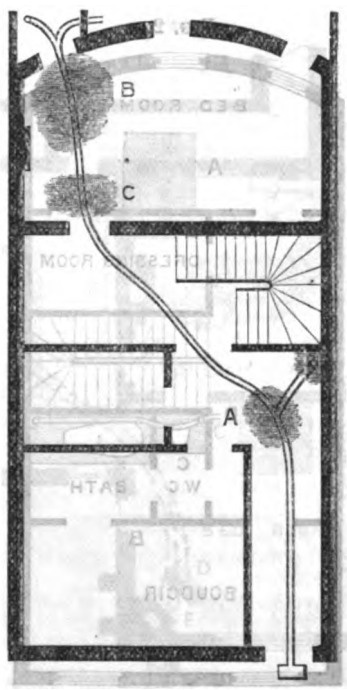
An Address
ON
DEFECTIVE SANITATION AS A CAUSE OF PUERPERAL DISEASE.



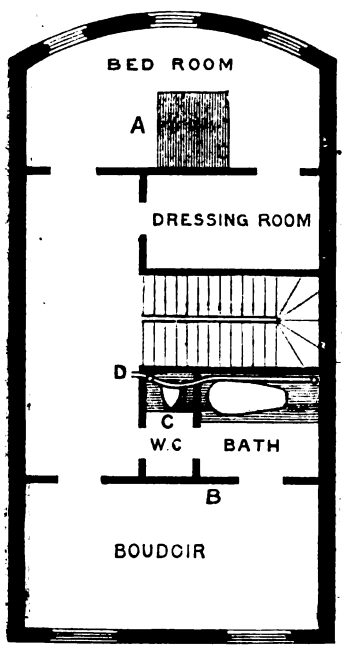
Delivered at the East London and South Essex District of the Metropolitan Counties Branch of the British Medical Association.

By W. S. PLAYFAIR, M.D., LL.D., F.R.C.P.,
PROFESSOR OF OBSTETRIC MEDICINE AT KING'S COLLEGE, AND PHYSICIAN FOR THE DISEASES OF WOMEN AND CHILDREN TO KING'S COLLEGE HOSPITAL.

GENTLEMEN,—When your Secretary, Dr. Hunt, did me the honour of suggesting that I should deliver an address at your opening meeting, the difficulty I experienced in acceding to his request was not the want of a subject, but rather the selection of one amongst the many topics connected with obstetrics and gynæcology which might be of sufficient interest to claim your attention for a short period. My first idea was to offer you a comment on some of the topics that have of late been especially discussed by gynæcologists, such as the more recent developments of abdominal surgery, particularly the removal of the uterine appendages and ovaries, which mooted point certainly calls for much more thorough discussion than it has yet received. I soon found that to enter on topics such as these in the brief period which I could occupy without unduly trespassing on your patience and courtesy involved an effort at concentration of which I was incapable. Dr. Hunt's invitation told me that a short paper of half an hour's duration or thereabouts would suffice, provided it was of a nature to elicit discussion; and I therefore resolved to direct your attention to a hardly appreciated source of septic disease, to which I have myself traced many otherwise inexplicable cases of septicæmia in childbirth, and to which my attention has been more particularly drawn within the last few months from the fact that I have had the misfortune to meet with what I believe to be a well-marked instance of it in the person of the wife of an esteemed professional friend, whose terrible illness was traced to this source. I refer to the poisoning of lying-in women from sewer gas, conveyed to the house in consequence of defective sanitary arrangements. Here at least is a topic which must interest you all, for if there is one thing more than another which the practitioner has to dread it is the development of this insidious and terrible illness after delivery, defying as it so often does the most strenuous and best-directed treatment, desolating happy homes, and too often leading to most undeserved blame and injury to the medical man who has the misfortune to meet with a case in his practice. This source of puerperal disease has scarcely received any attention at all, and it is hardly alluded to in our text-books, and yet I believe it to be very far from uncommon, and I trust I may elicit from your experience some corroboration of my views on this topic. I thus speak of it in my work on Midwifery: "Exposure to sewer gas may, I feel sure, produce the disease. In two cases of the kind I had the opportunity of closely watching, an untrapped drain opened directly into the bedroom, in one instance into a bath, in the other into a watercloset. Both cases were indistinguishable from the ordinary form of the disease, and in both improvement commenced as soon as the patient was removed into another room. In a case I saw some years ago at Notting-hill, the patient, who had been confined a week, had all the symptoms of a most intense attack of septicæmia, but none of a diphtheritic character, while her husband lay in an adjoining room suffering from a diphtheritic sore-throat. Here the waste-pipe of the bath was found to communicate directly with the sewer. In spite of her intense illness I had the patient removed to another house, and from that moment she began to improve. In two other cases in which the same source of disease was detected, the removal of the patient from the infected atmosphere was immediately followed by a marked amelioration in the symptoms. I know of three similar cases which ended fatally, in which I have every reason to believe that the cause of the disease was poisoning by sewer gas. Frankenhauser has related a curious case of the poisoning of four puerperal women by sewer gas. In fact, the whole question of defective sanitary conditions on the puerperal state deserves much more serious study than it has ever yet received, and I have long been satisfied that they have often much to do with certain grave forms of illness in the lying-in state the origin of which cannot otherwise be traced."

Now this quotation, which is only to be found in the later editions of my book, contains, I believe, a summary of nearly all that is known on this important topic, and you will see how little it is. It is surely high time that it should be more thoroughly worked out and studied, and although I have no pretension to-night to do more than to direct your attention to it, I trust that the endeavour may be of some practical use. I purpose therefore to describe more particularly some few illustrative cases of the kind, and to show you by rough diagrams how the sewer gas came to be brought closely into contact with the patient. I shall select four only out of the large number of cases I have seen and noted, in which no other source of disease could be traced, and in which its dependence on this cause may, I think, be taken as proved to demonstration. As I am now dealing with causation only, I shall not describe at all the symptoms of the patients; merely saying that all these cases were typical examples of the ordinary puerperal fever or septicæmia, not differing in any marked way from the usual types of that disease.

FIG. 1.



Let me first direct your attention to the case I have alluded to. I myself attended my friend's wife early in June last, and very shortly she developed a severe illness, accompanied by marked hyperpyrexia, the temperature constantly ranging over 104°, and continuing at this high level for over six weeks. It was only kept down by the use of Thornton's ice-cap and constant sponging with iced water. Two months after delivery large pyæmic abscesses formed; and I wish it could be said that even now, after the lapse of three months, convalescence was established. Now, in searching out the causes of this terrible illness the hygienic condition of the house was naturally investigated, with the results I shall show you. My friend entered his house on his marriage a year since, and believed that the sanitary arrangements had been thoroughly seen to. Unfortunately, the engineer to whom they had been entrusted had relied on the statement of the former owner that the main drain was in good

Digitized by Google

condition. Moreover, there existed the radical defect of having the closets and soil-pipe in the centre of the house, an arrangement quite incompatible with perfect sanitation. Now let me point out what was discovered. First, as to the basement (Fig. 1):—At A in the passage the new soil-pipe placed when the house was taken was joined to the old one, and at the junction there was a considerable leakage, and when uncovered the stench was intolerable. At B was found an old brick drain surrounded by sodden sewer earth, very foul. A large cartloadful was removed from the spot indicated below the floor of the kitchen. At C were two defective joints with considerable soaking through of sewage, and over these drains there was nothing but earth and kitchen boards. Dr. Dawson Williams, who conducted the investigation, very naturally says that he considered the above a very serious condition. Dr. Williams also points out that on the second floor not only was the sewer gas from the basement drawn up (Fig. 2), but the bedroom (A) where the confinements took place, the boudoir (B) where the patient chiefly lived, and the W.C. (C) "were practically in one." Besides the above, other but less important defects were found, such as a housemaid's closet, the waste-pipe of which opened directly into the soil-pipe (D).

Now, can it be reasonably doubted that this illness

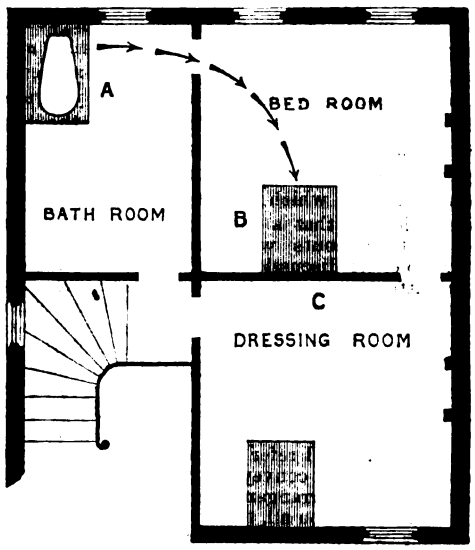


FIG. 2.

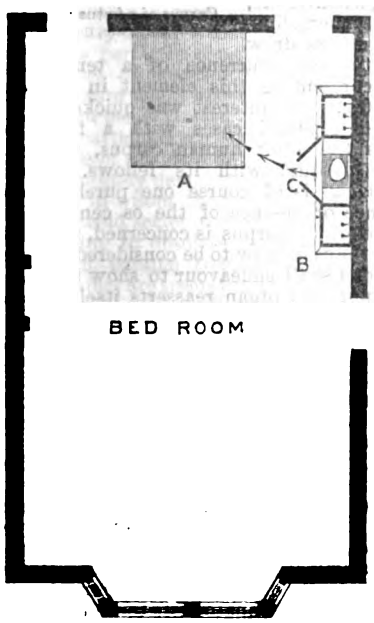
originated in this horrid state of things, since no other possible cause could be detected? Moreover, is not this a striking example of the way in which we are all placed absolutely at the mercy of workmen and plumbers? Here is the case of a member of the profession fully alive to the risks of defective sanitation, who in going into a new house spares no expense to have it properly drained, who employs a sanitary engineer for the purpose, with the results I have described above. It is a curious fact in connexion with this case, and I think it must be something more than a coincidence, that in the favourite professional street in which my friend lives I have myself seen four cases of puerperal septicæmia within the last five years, one of which proved fatal, and I have heard of three more, one of which proved fatal. Possibly there may have been more of which I am not cognisant. Now, in a street of 152 houses there can only have been a small number of confinements in five years, and if out of this small number seven were attacked with puerperal septicæmia, surely there is fair ground for suspecting that there exists some morbific cause localised in the street; for to suppose that there were seven cases of conveyed septicæmia in one street in five years is an assumption that is incredible. Now, all these houses are old, probably all were originally defective in their sanitary arrangements, and many may yet remain so. I do not wish to attach too much importance to the fact I have stated, but it is certainly striking and suspicious. I have often wondered whether in the good old days, when there was no such thing as a watercloset in existence, when foul smells were at least localised to the place of their origin, and when sewer gas was not ingeniously carried by a complex series of pipes to our very sleeping-places, true sanitation was not really better than it is now, when it is so much studied and so little practised.

Now let me show you a second example. This diagram (Fig. 3) represents the bedroom floor of a new house of considerable pretensions in Notting-hill, in which I saw a lady some years since, with her medical adviser, Mr. Hewer, in a very dangerous state from septic disease. The origin of her illness was discovered from the curious fact that her husband was lying ill at the same time in the bed in the dressing-room (C) with a severe diphtheritic sore-throat. This could hardly be a mere coincidence, and it pointed very strongly to some common cause of illness to which both had been subjected. The fact that his wife's illness showed no diphtheritic symptoms went for nothing in my judgment, for I have been long satisfied that septicæmia may be produced in lying-in women from zymotic poison—as, for example, the scarlatinal poison—without any of the specific

FIG 3.

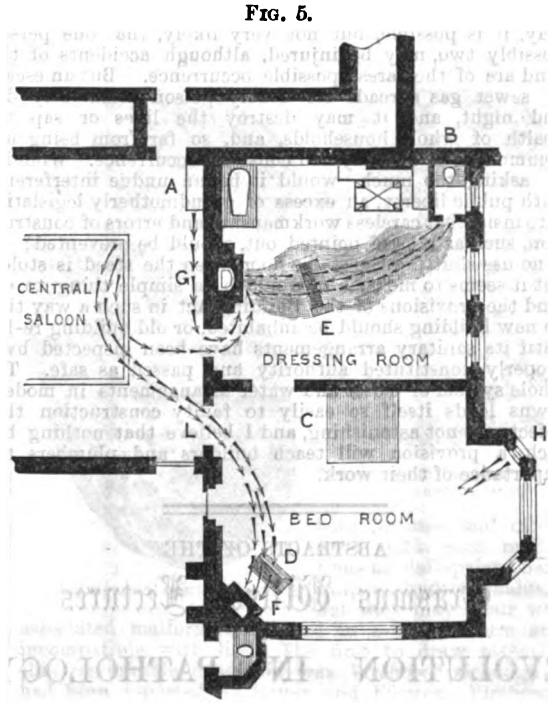
symptoms of the special poison producing it. Here the cause was not far to seek, for, amazing as it may seem, the waste-pipe of the bath (A), close to the bed (B) occupied until a few days before by both, went straight down the outside of the house to the main drain, into which it opened, so that the sewer was ventilated right into the dressing-room. As soon as this was detected, seeing that the patient must have been constantly inhaling fresh doses of poison, I had her removed, in spite of her critical condition, to her mother's house in a neighbouring street. The result most fully proved the correctness of the assumption as to the cause of her illness, for a marked change for the better at once occurred, and the patient was soon convalescent.



The next diagram (Fig. 4) represents a bedroom in a large house in the most fashionable part of the West-end, which had been recently taken and done up in the most costly way. I attended the lady of the house in her second confinement, and she lay in her bed at A. Shortly she developed well-marked septic symptoms, and I naturally investigated the sanitary state of the house to see if it threw any light on their origin. I could find nothing amiss. There was no bath or fixed washhand stand near the room, and the closets were at a distance, with the soil-pipe running down the outside wall, as it should do. It was not until some days afterwards that I discovered the extraordinary arrangement depicted in the diagram, which no one could possibly have suspected, and the knowledge of which the patient had given special directions should be withheld from me. At B is represented a very handsome and innocent-looking

Digitized by Google

piece of furniture which seemed to be a fixed wardrobe, to which purpose its ends were in fact devoted. The centre door, however, formed by a large mirror, opened on a concealed watercloset (C), which luxury no one could have looked for in such a situation. I subsequently discovered that this was a brilliant idea of her husband's, who actually had had a special soil-pipe carried through the centre of the house, which communicated directly with the main drain, with no ventilation, and who had thus contrived, at an enormous cost, to have a stream of sewer gas laid on close to his bedside. And be it remarked that builders and plumbers had carried out this ingeniously dangerous arrangement without giving him the slightest hint that it was either unusual or perilous. Of course as soon as I made this discovery I had the patient removed to another room, when her symptoms soon abated.



I could easily go on multiplying examples of this kind, but I shall content myself with one more case, which was thoroughly worked out, with very instructive results. It was that of a lady who was confined in the country of her first child, in a large and expensive house, newly built, and supposed to be supplied with all the most perfected sanitary arrangements. There was nothing particular about the labour, and for the first ten days the convalescence left nothing to be desired. On the eleventh day she got up and

FIG. 4.

lay on the sofa (Fig. 5, D) opposite the fire (F), which, as it was in January, was burning day and night. The day after, although she had a headache and felt poorly, she again got up and lay on the sofa. The subsequent day, although feeling very ill, she again insisted on getting up and lay on the sofa at E, in her husband's dressing-room. On the following day she was very ill indeed, with a temperature of 104° and a pulse of 130, and I was summoned to see her. It is needless to say more of her illness, which rapidly increased, except that, feeling satisfied it was caused by defective sanitation, I advised her removal to a house in the neighbourhood, in spite of the very grave symptoms that existed, with the most satisfactory result, for within twenty-four hours her temperature had fallen, and she rapidly became convalescent. Of course at this time nothing was known of what actually existed, but I was led to form this conclusion from the fact that a number of the servants and residents were suffering from sore-throats, and from being told that almost everyone who came to stay felt ill and out of sorts. Subsequently the sanitary state of the house was thoroughly investigated by one of the most distinguished sanitary engineers in London, from whose reports the accompanying diagram (Fig. 5) is copied. It is useless to enter into a description of all the abominations which were found to exist, which, in a house of the kind, in the building of which no expense was spared, were almost past belief. For the purpose of my story it will suffice to say that the smoke test showed that there was a very abundant escape of sewer gas into both the bedroom and dressing-room, which, from the fact that there were large fires burning constantly in both rooms, passed in a continuous current in the direction of the arrows. In addition, the plumbing work in the closet in the dressing-room had been so imperfectly done that its contents found their way out under the floor. Now, mark how thoroughly and curiously these facts prove the cause of the disease. The patient lay in the bed at C, which, from the accident of its being winter, and the current of sewer gas being drawn therefore to the chimneys, was quite out of its reach, and for the first ten days after her confinement, while she remained in bed, she was perfectly well. On the eleventh day, when she got up, she was placed directly in the current of sewer gas at D, and instantly got poisoned. On the twelfth and thirteenth days she was again exposed to the absorption of further and more intense poisoning; while immediately on her removal to fresh and uncontaminated air all her threatening symptoms disappeared. Remark also that there was nothing peculiar in the symptomatology, nothing different from an ordinary and rapidly progressing case of puerperal septicæmia. It seems to me that this instructive history is about as com-

FIG. 5.

plete a demonstration of the origin of puerperal disease from defective sanitation as anyone could possibly desire, and I can see no flaw in the chain of evidence.

It may probably be objected that most of these cases had been exposed for a length of time to the very influences which are supposed to have caused disease after labour, and that therefore the illness should have appeared antecedently. This is undoubtedly a fact difficult to understand, and of which I profess to offer no explanation. It is to be remembered that there are many things in connexion with puerperal fever "not dreamt of in our philosophy," and for which we are as yet quite unable to account. Doubtless future investigations will throw fresh light on this and other obscure points. It may be that delivery, and the exposure of large absorptive surfaces resulting from it, makes women susceptible to influences they previously resisted. It may be also—and I have seen many cases that lend weight to the assumption—that absorbed poisons may remain latent in the system, and only show their malefic influence after delivery. I well remember a terrible case which could not, so far as I can see, be explained except on this theory. It was that of a lady who had been residing in a hired cottage in the country, close to London, up to the time of her confinement. If I remember rightly,

Digitized by Google

she was confined before her medical man could reach her. Within twenty-four hours she was terribly ill, and was dead in a few days. The virulence of the septic influence may be judged of by the fact that one of the nurses in attendance pricked her finger, got rapid gangrenous poisoning, and had to have her arm amputated at the shoulder-joint. Is the conclusion not inevitable that the patient, who felt perfectly well on leaving the country, brought with her in some latent way the poison that developed with such deadly results? Some light is thrown on its origin by its being discovered that the cottage in which she had been living was in a most insanitary state, the details of which, however, I never learnt.

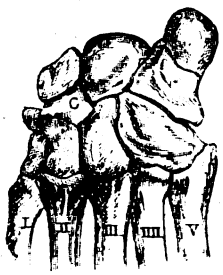
Now, of course, the question arises: If these risks are really so serious to lying-in women, as I contend they are, how are they to be avoided? Increased attention on the part of the profession may do something, but not much, for the demon plumber is abroad, and one may rest in fancied security that proper care has been taken, while the carelessness of a single workman may render all our precautions useless. The Building Act authorises the district surveyor to inspect every new building, and any fault of construction promising to be dangerous he has the power to have remedied; but in the very house the beams and floors of which he inspects, every bath and cistern may open into the sewers, and the contents of the soil-pipes may freely percolate under the floors; he may even be aware of these facts, and yet he has no power to interfere. Now, if a beam breaks or a floor gives way, it is possible, but not very likely, that one person, possibly two, may be injured, although accidents of this kind are of the rarest possible occurrence. But an escape of sewer gas spreads its deadly poison insidiously day and night, and it may destroy the lives or sap the health of whole households, and, so far from being uncommon, it is of daily and constant occurrence. Would it be asking too much—would it be an undue interference with public liberty, an excess of grandmotherly legislation—to insist that careless workmanship and errors of construction, such as I have pointed out, should be prevented? It is no use shutting the stable door when the steed is stolen, but it seems to me that it would be a simple thing to extend the provisions of the Building Act in such a way that no new building should be inhabited, or old building re-let, until its sanitary arrangements have been inspected by a properly constituted authority and passed as safe. The whole system of closet and water arrangements in modern towns lends itself so easily to faulty construction that defects are not astonishing, and I believe that nothing but such a provision will teach builders and plumbers the importance of their work.

ABSTRACTS OF THE
Erasmus Wilson Lectures

EVOLUTION IN PATHOLOGY.

Delivered at the Royal College of Surgeons of England,

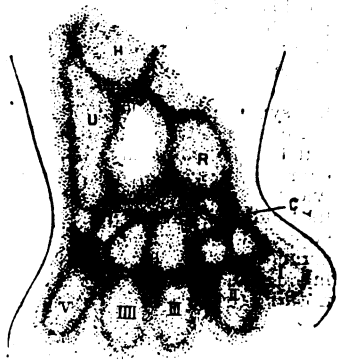
BY J. BLAND SUTTON, F.R.C.S.,
ASSISTANT-SURGEON TO THE MIDDLESEX HOSPITAL.



LECTURE I.

SUPPRESSION OF PARTS.

MR. PRESIDENT AND GENTLEMEN,—Last year I endeavoured to show that the three laws formulated by Professor Huxley as expressions of the principles concerned in evolution, in so far as they relate to anatomical details, are equally applicable to pathological anatomy. The first law—*There has been an excess of development of some parts in relation to others*—was abundantly illustrated under the term "hypertrophy." In the present course full attention will be devoted to the second law—*Certain parts have undergone complete or partial suppression.* A careful consideration of this law leads to important conclusions, and renders intelligible some very obscure conditions, which have excited more or less curiosity in the minds of pathologists.



The first example is merely chosen to serve as a clear instance of the process termed "suppression." Recent researches indicate, beyond all doubt, that an ossicle has been suppressed in the human carpus. In the manus of a very large number of vertebrates, beginning with tailed amphibians and passing onwards to primates, wedged in between the proximal and distal row of the carpal bones, we find an ossicle known as the "centrale." A typic carpus, taken from a baboon, is represented in Fig. 1.

FIG. 1.

Carpus of a baboon, showing the os centrale.

FIG. 2.

Carpus of a fœtus with the rudimentary centrale, c (after Leboucq).

This bone became very interesting when Henke, Reyher, Rosenberg, Kölliker, and others drew attention to the occurrence of a temporary nodule of cartilage representing this element in the carpus of the human fœtus. The interest was quickened when Gruber and Turner reported cases with a fully developed os centrale in the adult human carpus, taking rank with, and being coequal with its fellows. The illustration chosen (Fig. 2) is of course one purely anatomical, and the existence or absence of the os centrale, in so far as the function of the carpus is concerned, is of little moment. In most of the cases now to be considered the matter is very different, for I shall endeavour to show that in many cases where a suppressed organ reasserts itself, in some it gives rise to serious malformations, and in others is a source of danger, inasmuch as the parts are not infrequently the starting-points of abnormal growths. To trace the ancestral history of these structures and to decipher their meaning is, in many instances, exceedingly difficult, but the quest is surrounded with fascination, and is one of the most enjoyable occupations which fall to the lot of the scientific pathologist. It is rendered more delightful from the fact that the investigator is obliged to carry his inquiries into the remotest realms of biological science, and gather evidence in support of his case from animals which have long since passed away, now only known to us by their bony framework. All mammals possess in their brain a striking illustration of the truth of this remark, for the pineal body, imagined by the older anatomists to be the seat of the soul, has now been shown by Mr. Baldwin Spencer to be the remnant of a median eye, which still persists in a rudimentary form in lizards. It was most highly developed in extinct amphibians, being probably a functional sense organ of pretertiary periods. The fact of the pineal body originating as a tubular diverticulum from the thalamencephalon is very suggestive, and that it should be the seat of aberrant formations may be anticipated. Weigert, Virchow, Wilks, and Drs. Charlewood Turner and Silcock have described specimens of a cystic condition of the pineal body in the human subject.

One of the clearest instances of suppression, and at the same time one capable of indisputable demonstration, is connected with the disappearance and occasional reappearance of a third incisor tooth in man. The matter was first worked out and announced by Professor Albrecht (now of Hamburg) in quite a number of papers, that normally man inherits three incisors on each side in the upper maxillæ, but during development the middle (second) one of the three is suppressed. In many cases of cleft palate, however, more room is afforded, and the usually suppressed tooth attains a functional condition. The question was one of importance, and I was able in a paper read before the Odontological Society of Great Britain in December, 1884, to confirm this part of Albrecht's observation. Professor Sir W. Turner, a month later, adduced also confirmatory testimony in the

Digitized by Google

Journal of Anatomy and Physiology, vol. xix.; and the last contribution in this direction is by Windle and Humphry in the same journal. A careful analysis of the facts shows, beyond all doubt, that in the usual course of events an incisor tooth is suppressed in the upper maxilla of man; the only point admitting of any latitude of opinion is whether the missing tooth is the second or third incisor. As the case stands at present the balance of opinion is in favour of it being the second.

We must not forget, however, that supernumerary teeth are found in other situations than in the incisor series; indeed, they may occur in almost any part of the dental arch, and may vary in character from a perfectly formed enamel-covered tooth to a tiny conical mass of dentine. In determining whether an extra tooth is a supernumerary one or not, we must also take into consideration the fact that an excess in the number of teeth is occasionally due to the retention of one or more milk teeth. In order to comprehend the true significance of supernumerary teeth, it is necessary to bear in mind the morphology of these organs. In their essential features the teeth of a shark agree with those of a mammal, and in their development as calcified papillæ of the involuted epiblast in the buccal region the stomodæum—the two forms are in perfect harmony. In the case of the shark almost the whole of the mouth is beset with teeth, whereas in mammals they are normally restricted to certain very definite tracts. An unprejudiced survey of the facts ought to convince us that though the teeth of mammals are thus kept within narrow limits, yet the papillæ in the immediate vicinity of these teeth territories are potentially teeth, and it is perfectly consonant with what we know of the principles of atavism that these papillæ should occasionally declare their ancestry by developing as rudimentary, or even perfect, teeth. Nor is this form of atavism limited to this particular region; for, inasmuch as teeth are modified papillæ of the skin or integumental covering (and this may be absolutely demonstrated in the case of the young of the dog-fish, in whom the various stages may be clearly traced from placoid scales to teeth), so in those remarkable teratomata arising in obsolete canals lined with epiblastic tissues, calcified papillæ (teeth) make their appearance. Dentine and enamel are tissues which exist in scanty proportions in man, yet they formerly occurred in great abundance in the remarkable mailed-ganoids which are encased in an elaborate armour of these very extraordinary tissues.

If we admit the above opinions, then a rational explanation is forthcoming of certain interesting pathological conditions which occur in the mouth. For instance, some forms of odontomata may be considered as aberrant involutions of buccal epiblast and papillæ; the view is supported by the fact that this variety of neoplasm occurs in many mammals. There is also good evidence to support the view that the milk dentition is to be regarded as a set of teeth appearing in obedience to the law of inheritance. In many mammals they are, like the lanugo of the human fœtus, shed before the embryo quits the uterus. If supernumerary teeth can be regarded as atavistic, then we must consider certain pre-calcific stages of teeth in the same light; for instance, in the early stage a tooth consists of an up-growing papilla capped by a down-growth of epithelium. Suppose the development to advance no further, but growth to continue, the result is an aberrant formation—a neoplasm. Involutions of this kind have been detected by Malassez, and Mr. Eve has discussed their relation in connexion with multilocular cystic tumours of the jaws. The upshot of the argument is this: supernumerary teeth, odontomata (excluding the cementomata of herbivora), and multilocular cystic tumours of the jaws may be regarded as originating in the germs of teeth suppressed in the process of evolution of our species. The incisor tooth, to the consideration of which the early part of the argument was dedicated, may be considered, in all probability, as the last tooth in the order of suppression.

In addition to neoplasms originating in undeveloped enamel germs, we have to take into consideration a class of tumour usually described somewhat vaguely as adenomata, growing from the palate. Our knowledge of these cases is much advanced by the work of Mr. Stephen Paget on this subject. It appears that neoplasms, perfectly innocent in their nature, but full of epithelial nests, occur in the palate, and there are good grounds for believing that many of the growths variously described as glandular, alveolar sarcoma, alveolar carcinoma (!) &c., have their origin in little rounded masses of epiblast, which become enclosed between the two horizontal plates, which fuse together in the median line in order to separate the nasal and buccal cavities. The existence of such isolated epithelial islets has been affirmed by more than one observer, and a good account of them, with references to the literature of the subject, will be found in Lebouccq's papers on "Le Canal Naso-palatine chez l'Homme," and Note sur les Perles Epithéliales de la Voûte Palatine."[1]

In the museum of the Middlesex Hospital, standing side by side in the section devoted to injuries and diseases of the kidney, are two specimens; each in the words of the catalogue is thus described:—"A kidney, which is enlarged to three times its natural size, and is almost entirely made up of a congeries of cysts, varying in size from a walnut to a pin's head, separated from one another by a narrow band of renal tissue. The pelvis and ureter were not dilated. The normal shape of the organ is retained, but no distinction is visible between the cortex and medulla." The kidney, I have since been able to determine, was removed from a fœtus at term, and its general appearance may be gathered from Fig. 3. Few can have conducted many pathological examinations of fœtuses without encountering such a case. I have examined ten such kidneys. A goodly number are recorded in the Transactions of the Pathological Society, and many of the pathological collections in London possess examples of the condition. This cystic state is not confined to human kidneys, for I have studied them in calves, sheep, asses, and horses. Such kidneys are usually found in still-born fœtuses, and often coexist with such malformations as cleft-palate, hare-lip, talipes, hydrocephalus, &c.; but they may occur without associated malformations, and in a milder form are not incompatible with life. The first to draw attention to this remarkable condition was Virchow,[2] although cases had been reported by Rayer and Förster. Virchow considered the cysts to arise by ectasia of the uriniferous tubules, in consequence of obstruction to the tubules, the result of disease during intra-uterine life; in the majority of specimens the pelvis of the kidney is absent. The cysts contain fluid which numbers among its constituents urates. The ureter is excessively thin, but always pervious, and the renal artery excessively attentuated. Often the kidneys are of the horseshoe pattern. In rare cases a tract or a few patches of normal renal tissue is present. The researches of my friend, Mr. S. G. Shattock, put the matter on a totally different footing. By great good fortune a fœtal kidney in a less advanced stage and with a perfect pelvis came under his observation, and microscopic examination showed that the walls of the cysts were lined with tessellated epithelium. Comparison of sections from this kidney were carefully made with sections of the mesonephros (Wolffian body) of a human fœtus, and their identity established. Whilst Mr. Shattock was working in this way, I adopted an independent method, and compared sections of congenital cystic kidneys with

Digitized by Google

specimens prepared from an abnormally large paroophoron in a fœtus, beside numerous smaller ones. The conclusion derived from the study was irresistible—viz., that in these enormous cystic kidneys, whether they occur in the fœtus or adult, are to be regarded as persistent mesonephritic (Wolffian) tubules which have become cystic (retention cysts). The amount of mesonephritic tissue varies in different cases, and in most a certain proportion of metanephritic tissue is present. Mr. Shattock's observations on congenital cystic kidneys are not only directly confirmed by what we know of mesonephritic remains composing the paroophoron, and the great tendency they exhibit to form cysts, but they shed much light on the innocent variety of cystic disease of the testis. In this case the cystic spaces are lined with tessellated epithelium, and arise from the dilatation of the collection of mesonephritic remains familiar as the organ of Giraldès, situated between the testis and the epididymis. The general appearance of this affection recalls that of the congenital cystic kidney. (Fig. 4.) Thus developmentally, structurally, and in pathological tendency, congenital cystic kidney, the innocent form of cystic testicle, and paroophoron cysts are identical.

Among suppressed organs of pathological import must be mentioned the pedicle of the allantois—familiar as the urachus. Although normally persistent as a shrunken, impervious cord, passing from the summit of the bladder to the umbilicus, it may occasionally retain its patency for a long period after birth. In some instances it may grow equally with the bladder, retain a communication with that viscus, and give rise to a so-called bifid bladder. It may dilate unequally and form a chaplet of small cysts, and in some rare instances may serve as the starting-points of a cystic tumour (outside the peritoneum) of enormous dimensions. In one case I had an opportunity of examining and reporting upon with Dr. Aveling for the Gynæcological Society, the tumour weighed nearly five pounds. A careful account of some examples of this kind of cyst has been furnished by Mr. Lawson Tait in the *Gynæcological Journal*, vol. ii., in a remarkable paper on "Extra-peritoneal Cysts."

Among the most extraordinary instances of suppression of parts, with retention of an original function, known to me, is exhibited by the prostate. Morphologically, this organ, with its utriculus, glands, and muscle fibre, is to be regarded as a diminutive uterus. Careful analysis of its mode of development shows very conclusively that it is the homologue of the uterine cervix and upper segment of the vagina. These portions of the female reproductive organs are formed from that part of the Müllerian ducts which, in the oviparous vertebrates, constitutes the shell-forming segment. All surgeons and pathologists must be familiar with the small concretions so constant in the recesses of this organ in adults, and which have been so well described by Sir Henry Thompson in the Medico-Chirurgical Transactions (vol. xl., p. 78, 1857). In constitution and composition they agree with egg-shell, and they are formed in parts strictly homologous in reptiles, birds, and mammals. Thus man has in his prostate, morphologically, structurally, and functionally, an unimpeachable witness testifying to an ancestry with the feathered tribe, low down among the oviparous reptiles.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.—The annual meeting of this Association was held on the 28th ult. The report of the committee showed continuous prosperity, with a steady increase of funds. The following resolution was passed:—"That the Manchester Medico-Ethical Association expresses its approval of the action taken by the Apothecaries' Society of London, to obtain admission to the Conjoint Examining Board for England, together with the Royal Colleges of Physicians and Surgeons of London." The following gentlemen were elected office-bearers and members of committee for the year:—President: Dr. H. Simpson. Vice-Presidents: Drs. H. Ashby, W. H. Barlow, S. Buckley, and F. M. Pierce. Treasurer: Dr. D. Lloyd Roberts, F.R.S. Ed. Secretaries: Mr. J. Broadbent and Dr. A. Wahltuch. Committtee: Drs. F. H. Collins, A. Emrys-Jones, S. H. Owen, T. C. Railton, W. J. Sinclair, and W. Walter, and Messrs. H. A. G. Brooke, J. C. Clarke, J. Hewett, J. Foster, H. P. Ilderton, and G. H. Pinder.

THE Bournemouth Improvement Commissioners contemplate spending £9000 in a scheme for supplying the town with sea water for street-washing and sewer-flushing. The gas and water company have objected, and it is necessary that their consent to the scheme be obtained.

ABSTRACT OF THE

Lettsomian Lectures

ON SOME OF THE

MENTAL AFFECTIONS OF CHILDHOOD AND YOUTH.

Delivered before the Medical Society of London, January, 1887,

BY J. LANGDON DOWN, M.D. LOND., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE III.

Infantile Insanity.—Infantile mania is not of frequent occurrence, and has not been the subject of much comment. Dr. Down has observed recurrent attacks of acute mania in young children. Cases having well-marked delusions of suspicion have also been met with. The ordinary trustfulness of childhood has been replaced by painful mistrust. The lecturer had seen some cases of melancholia associated with manifest delusions, one boy believing that he resembled an animal. In one case of homicidal mania in a little girl who subsequently became epileptic Dr. Down thought that the maniacal paroxysm was really masked epilepsy. As puberty approaches attacks of mental aberration assume a special character; there is frequently unnatural introspection, and a critical hyper-conscientiousness becomes prominent. Sometimes such patients avoid making any positive assertion lest the exact truth should not be spoken. These cases cause great anxiety at the time, and occasionally end in a permanent break-down. Many, however, by careful management may be tided over the climacteric period of puberty, and then all may go well. It is important to be on guard against concealed suicidal impulse and to note its slightest indication, as the tendency in such cases is to melancholia, and in some cases to self-inflicted injury. Care should be taken that there is no sexual deviation. If present it should be treated as a physical evil, and to be corrected for the good of the body. Sexual deviations are readily recognised by the supra-orbital headache, dilated pupils, brown umber areolæ surrounding the eyes, averted look, and statuesque bearing. Occasionally the latter is so marked as to resemble a minor cataleptic state.

Moral insanity is met with in childhood and youth. Such are cases of purposeless theft, lying, or mischievousness. The subjects of this condition are sometimes intellectually bright, and have an amount of address which makes them extremely troublesome to their friends. More frequently moral insanity is associated in childhood and youth with some amount of mental backwardness. The backwardness may be very slight, but the manifestations of moral insanity may be multiform. A dangerous form of moral insanity is incendiarism. Many forms of low cunning are developed in backward boys by associating them with others of more wit. Under such circumstances the backward boy calls to his aid lying, theft, and deceit to compensate for his intellectual weakness. The moral sense in these cases may be regained or developed when removed from their injurious surroundings and submitted to appropriate training. Idiot *savants* are feeble-minded children who exhibit some faculties developed to excess. Some such could carve and draw with great skill. Extraordinary memory is often met with associated with very great defect of reasoning. One boy, in reading Gibbon's "Rise and Fall of the Roman Empire," skipped a line on the third page at his first perusal. Ever after, when reciting from memory the stately periods of Gibbon, he would, on coming to the third page, skip the line and retrace his steps just as when he first re-committed the passage to memory. Often the memory takes the form of remembering dates and past events. One boy never failed to tell correctly the name and address of every confectioner's shop he had visited in London, and could as readily tell the date of every visit. The faculty of number is usually slightly developed in feeble-minded children, while memory is fairly well developed; yet occasionally the power of mental arithmetic has been well developed. Improvisation is an occasional

Digitized by Google

faculty. Memory of tune is a very common faculty among the feeble-minded; they readily acquire simple airs and rarely forget them. In none of the cases of idiot *savant* had there been any history of the possession of a similar faculty by the parents or sisters or brothers. In one case a necropsy had been made. The boy had a remarkable, indeed perfect, appreciation of past or passing time. There was no difference from an ordinary brain, with the exception that there were two well-marked and distinct soft commissures. Dr. Down's explanation of the phenomenon was that, as every movement of the house was absolutely punctual, he had data from which he could estimate the time by accurate appreciation of its flux. All these cases of idiots were males. Every form of mental deviation may be met with in the congenital feeble-minded. They may become the subjects of acute and chronic mania, of acute and chronic melancholia, and of dementia. Occasionally under the influence of acute mania, the feeble intellect of the youth becomes fanned into a brighter flame. The taciturn may become loquacious; the timid and respectful, proud and defiant; the amiable and tractable, abusive and destructive. Three remarkable instances have occurred to Dr. Down of boys who had never been able to speak making use of well-formed sentences during the high febrile state of acute pneumonia or scarlatina. There are two ailments from which the congenital feeble-minded are remarkably free—chorea and hysteria. Chronic and persistent incoördinate movements may be seen, but not the acute attacks so common in a general hospital. Perhaps it is partly owing to the lessened emotional life of the patients. The same reason may account for the rare occurrence of hysteria. This defective emotional element in the feeble-minded spares them much grief. Epilepsy is a common complication of feeble-mindedness. Of the whole number of Dr. Down's patients 24 per cent. have been at some period or other epileptic. Dr. Kerlin of Pennsylvania gives nearly the same percentage. Epilepsy often appears for the first time at puberty, and subsequently disappears. Occasionally the status epilepticus supervenes with the worst possible results. Catalepsy is met with among the feeble-minded, but always associated with impure habits.

The *physical deviations* of the feeble mind are important. They are very prone to eczematous eruptions in the flexures of the joints and behind the ears. The skin gives evidence of degeneration in its tendency to unnatural unions, just as the petals of the corollifloral exogen indicate a lower grade than the distinct petals of the thalamifloral. So do webbing of the toes and fingers and adhesions of the lobules of the ears suggest marked inferiority. Abnormalities of the ear were frequent in people of a degenerate type: lobules absent, lobules adherent, helices defective, and the entire pinnæ misshapen or shrunken, are very common. The development of the hair offers some anomalies; some of the feeble-minded are hirsute over the whole body, and 11 per cent. have the eyebrows continuous over the nose. The tongue is very badly coördinated; at the usual time for commencing to speak, 36 per cent. were found to be speechless, and 30 per cent. could speak but little, whilst not more than 28 per cent. could speak fluently. Mastication is often defective; deglutition is often hurried. Rumination occasionally occurs. The appetite may be perverted, pebbles and other things being swallowed without ill effect. The organs of reproduction are ill developed—small ovaries and undeveloped or undescended testes. The reflex functions are defective. Constipation is common. Emesis difficult to excite. Absence of cough and expectoration when the subjects of phthisis was also to be explained in the same way. The vaso-motor system is very sensitive. Sudden change of weather easily excites gastro-intestinal trouble. Bolting food, or over-eating, or taking too much meat, or electrical disturbances are other common causes of catarrh of the bowels. Disseminated sclerosis, shown in the characteristic gait and scanning speech, may be observed; but more frequently pseudo-hypertrophic paralysis is manifested in the feeble-minded. Diseases of the liver and kidneys are extremely rare, owing to the discreet and temperate habits which such patients are accustomed to lead under medical guidance. Rheumatism is very exceptional. Diseases of brain and lungs are the chief causes of death, putting aside the diseases of childhood. Dr. Fletcher Beach found that about 2½ per cent. of the average daily number of inmates of the schools at Darenth die from epilepsy, or more than the mortality of London from all causes. The prevalence of phthisis as a cause of death depends very much on the nature of the soil on which they reside. In the year 1867 Dr. Down wrote a paper in THE LANCET "On the Relation of Idiocy to Tuberculosis," in which he showed how prevalent phthisis was among idiots, amounting to 39 per cent. of the general mortality. Nothing is more remarkable than the readiness with which feeble-minded children succumb to acute disease of any kind, or the way in which they are affected by climatic changes. The onset of illness should be narrowly looked for and promptly treated. The thermometer is of great value in detecting the early signs of disease and the need for early precautionary measures. Loss of appetite was the indication most relied on of illness before the introduction of the clinical thermometer. As to height and weight of idiots, Dr. Down's observations agreed with those of Dr. Shuttleworth and Dr. Tarbell of America. They are shorter and lighter, but the relative rate of growth of the two sexes of idiot children follows the same rule as that of normal children, and is subject to the same variations at puberty.

Diagnosis.—The diagnosis is important both for training and forensically. The profound cases are easily diagnosed, especially if associated with marked asymmetry of cranium or microcephalism. The congenital class is that which has to be considered in early life. The instinctive process of feeding is often acquired with difficulty, and indicates that there is no predominance of instinct in infancy. The young animal is on a higher platform than an idiot baby so far as instinct is concerned. There is a marked indisposition to make muscular effort. There is no responsive leap when the feet are allowed to touch the ground. No disposition to crawl. The power of standing is long deferred, and walking may never be attained. There may be much difficulty in diagnosing the accidental cases. They are, as a rule, fleet and mobile and mischievous to a degree. Irritated by constraint and intolerant of cephalic examination, they alternate their mischievous pranks with shrill shrieks and unmeaning cries. They rarely speak, are fond of feeling things with their tongue, and run about in search of fresh objects for indulging this freak. They live entirely in a world of their own. Slavering is a very common sign among the members of the three classes, arising sometimes from inattention, or from the hyperæmic condition of the salivary glands, from prognathous form and inadequate size of jaw, from want of muscular power of lip, from incoördinate movements of the tongue, and sometimes from a combination of two or more of these conditions. Automatic movements are also common. These may consist of rotatory movements of the head on its axis, from side to side, and rhythmical movements of the fingers before the eyes.

Backwardness.—There are a large number of boys and girls who are dull and backward, who develop tardily, but do eventually attain to a fair amount of intellectual power. These are the *enfants arrières* of French writers. For diagnosis the question to be answered is, Can we in imagination put back the age two or more years, and arrive thus at a time perfectly consistent with the mental condition of our patient? This would be possible with a backward but not with an idiotic child.

Absence of speech may be ascribed to deafness or congenital defect of hearing; to defective formation of the tongue, palate, or lips; to defective mental power, the child having no idea, or being incapable of converting ideas into words.

Anatomy.—The weight of the brain may be very considerably diminished in the microcephalic or Aztec types. The brain is not always simply retarded in growth. Too early synostosis could not be the cause of microcephalism. There is defect of development as well as of growth. The development of convolutions was not arrested equally at all parts of the brain. In one case—the brother of the patient whose brain was described by Mr. Marshall—the occipital lobe had developed but slightly. The convolutions were less complex, smoother, and with fewer secondary sulci than those of the orang or chimpanzee. The supra-marginal lobule, and the second connecting convolution were almost absent. The first convolution was very simple. There was a calcarine lobule, but not any accessory fold uniting the second ascending fold to the supra-marginal lobule. In these features the brain resembled the quadrumanous cerebrum. The want of symmetry, of an operculum, of the two internal connecting convolutions: the position of the bent fold in regard to the fissure of Sylvius; the complete junction of the calloso-marginal and the middle temporal or uncinate convolution—were characters

Digitized by Google

essentially human. Asymmetry of the brain is common. The occipital lobe is often undeveloped. Hypertrophy of the brain is not unfrequent. A huge cranium with completely ossified sutures may coexist with a hypertrophied brain. The cranium may be greatly thickened. More or less complete absence of commissures may be met with. The corpus callosum has been absent in 2 per cent., and the soft commissure in 8 per cent., of Dr. Down's post-mortem examinations. Pallor of the grey matter is of very frequent occurrence. Indeed, nothing is more striking than the frequent mention of whiteness of this part. Dr. Down could not but think that this phenomenon afforded indications for treatment and hopeful prognosis—as to the possibility of functional improvement of the brain.

Treatment resolves itself into physical and medical, and moral and intellectual training. Treatment should be begun betimes. Early training is of importance in preventing the growth of bad habits. Dr. Down avers that he knows nothing of cataclysmal improvements at seven and fourteen years of age. These ages are developmental crises full of danger. The most successful training is effected by placing the child with its peers, and not with its superiors. Intelligent children will not take part in the amusements and games of feeble-minded ones. It is important to rescue the feeble one from a *solitary* life, to give him companionship with his equals, and to place him in a condition where all the machinery moves for his benefit, where he is surrounded by influences of art and nature calculated to make life joyous, to arouse his observation, and to quicken his power of thought. In the families of the wealthy feeble-minded children do not receive the needful education and the necessary attention. It must always be kept in mind that the basis of all treatment should be *medical* in the large sense of the word. Success can only be attained by keeping the patient in the highest possible health. This is demonstrated by the increased intellectual torpor that accompanies deterioration of bodily health, and also by the diminished intellectual vigour observed in cold weather. A very liberal dietary is of great importance. It should contain a fair quantity of nitrogenous elements, and be rich also in phosphates and oleaginous constituents. Green vegetables are very essential as a valuable antiscorbutic. Too much farinaceous food should be avoided. Semolina, entire wheat flour, or macaroni are the best. The food must be easy to masticate. The bed- and sitting-rooms should be spacious, well warmed, and ventilated. The skin should be frequently sponged; the exhalation from it in the feeble-minded is something *sui generis*. A gravel soil, with well-made walks and plenty of out-door exercise and warm clothing, are most necessary. Summer brings with it a remarkable immunity from disease. Gymnastics, massage, and galvanism are employed to improve the condition of the muscles. Volitional movements should take the place of automatic ones. Simple ones are first practised. Finger lessons should precede tongue lessons. Dr. Down always remembers the pinioned Frenchman who entreated that his arms might be freed because he wanted to speak. The physical quality of the brain and other nervous centres must be improved, and this will bring the patient into practical relation with the external world and initiate reasoning. The *moral* training is of great importance. The patient's will must be brought into subjection to that of another. He has to learn obedience, that right-doing brings pleasure, and wrong-doing deprivation of pleasure. The affective faculties should be so cultivated that loss of the teacher's love should be felt as the greatest punishment, and *vice versâ*. In this way indications of untruthfulness, selfishness, obstinacy, sensuality, theft, and unkindness are checked. Corporal punishment should be strictly forbidden. Nothing is worse than deprivation of food as a punishment for an offence. Moral delinquency may be the result of mental excitement, the outcome of defective nutrition. The *intellectual* training must be based on a cultivation of the senses. They should be taught the qualities of form and the relation of objects by the sense of touch; the colour, size, shape, and relation by sight; the understanding of the various sounds; the qualities of objects presented to taste or smell. The concrete, not the abstract, should be taught. Dressing and undressing should be taught. Habits of order and neatness, of dexterity in the use of the knife, spoon, or fork, of precision in walking and handling, should be inculcated. Defective speech is best overcome by a well-arranged plan of tongue gymnastics, followed by a cultivation of the purely imitative powers. Monosyllabic sounds having concrete representatives should be first taught. The transactions of buying and selling may be easily arranged for amongst the patients themselves. House and school instruction should be supplemented by gardening and farming operations. The lathe, the fretwork machine, carpenter's bench, and printer's shop are useful appliances and means. For girls kindergarten occupations and the various elegancies of needlework may be the outcome of persevering effort. Music and dancing may, for all, alternate with dramatic entertainments, which appeal to eye and ear.

A CASE OF WOUND OF THE COMMON FEMORAL VEIN; SECONDARY HÆMORRHAGE FROM THE COMMON FEMORAL ARTERY; SEPTICÆMIA; DEATH.[1]

By A. PEARCE GOULD, M.S.,
ASSISTANT-SURGEON TO THE MIDDLESEX HOSPITAL.

THE wound of a vein is, as a rule, less serious and more easily dealt with than a wound of the corresponding artery, and for this among other reasons wounds of veins have received but scant notice at the hands of most surgical writers. Wounds of very large veins, however, are very grave injuries, and there are several interesting questions connected with their treatment which may be considered as still open to discussion. Having recently had to treat a case of wound of the common femoral vein attended with grave complications, I have thought an account of it might be considered worthy of attention.

On the evening of Oct. 11th, 1886, M. M——, an Italian ice-cream seller, was stooping down in the street, when on rising he came in contact with the knife of a cat's-meat woman who was standing by his side, the knife entering his left groin. Blood flowed very freely, and he went to a neighbouring chemist, who applied a pad and bandage and sent him to Middlesex Hospital. On his arrival at the hospital the hæmorrhage had ceased, but while the house-surgeon (Mr. Livermore) was preparing to readjust the pad the man vomited, and at once a full stream of venous blood spurted from the wound. A compress was firmly bandaged on and I was sent for.

I found the man pale, cold, and rather faint from loss of blood, and as the hæmorrhage had been so abundant I determined to secure the wounded vessel. An anæsthetic was administered by Mr. Fardon, and a Petit's tourniquet was applied to the thigh *below* the wound. The wound was a clean cut half an inch long, immediately below and parallel to Poupart's ligament and exactly over the common femoral artery; a probe passed into it slipped downwards and inwards. There was no alteration in the femoral or tibial pulse. I enlarged the wound by a vertical incision about three inches long, and turned out a considerable quantity of clotted blood which was lying beneath the fascia lata; upon this very free venous hæmorrhage ensued, which was with difficulty held in check by digital pressure above the wound. I then passed my finger into the bottom of the wound, and found that it passed quite into the common femoral vein through a wound which severed the whole anterior segment of the vessel. A ligature was passed around the vein above and below the wound and tied. This did not arrest the bleeding, which was then seen to come from the internal saphena vein, which entered the femoral just opposite the wound; a ligature was passed around this vein and tied. But blood still welled up from the wounded vessel, and a further search showed that another vein entered the femoral trunk just opposite the wound in the segment between the two ligatures. This vein was tied, and then all hæmorrhage was found to be arrested. The ligatures were of carbolised silk. The femoral vein was divided between the two ligatures. The man lost a good deal of blood during the operation, which was attended with considerable difficulty owing to the impossibility of completely arresting the hæmorrhage by pressure above and below. The femoral artery was clearly seen during the operation, but was apparently uninjured. The wound was very thoroughly irrigated with solution of

CASES OF WOUND OF THE FEMORAL VEIN.

Surgeon.	Reference.	Injury.	Treatment.	Result.
Langenbeck	Langenbeck's *Archiv*, I., 1	Wound of femoral vein during removal of sarcoma of groin	Ligature of femoral artery	Recovery
Oettingen	"International Encyclop. of Surgery," vol. iii. (Dr. Lidell's article)	Wound of femoral vein during removal of tumour of groin	Double ligature of vein; ligature of femoral artery	Recovery
McClellan	Ditto	Wound of the internal saphena vein at the entrance to the femoral vein, during excision of tumour in the groin	Lateral ligature of the femoral vein	Recovery
Roux	*Gazette des Hôpitaux*, 1853 (quoted by Nicaise)	Wound of femoral vein above saphena during removal of tumour in the groin	Double ligature of the femoral vein	Recovery
McClellan	Dr. Lidell, *op. cit.*	Wound of femoral vein and exposure of the femoral artery by a blunt hook	Ligature of femoral artery; compression of wounded vein	Gangrene of leg; amputation; recovery
Ollier	Quoted by Nicaise	Wound of femoral vein in groin	Suture of skin wound; light compression	Recovery
Delore	Ditto	Wound of femoral vein	Compression above the wound	Death from hæmorrhage
Roux	Ditto	Compound fracture of the middle third of the femur; wound of the femoral vein	Wound enlarged; hæmorrhage arrested by plugging	Recovery
Larrey	Quoted by Nicaise (*Clin. Chir.*, t. iii.)	Sabre-wound of groin dividing saphena vein at the entrance to the femoral vein	Ligature of femoral and saphena veins	Recovery
Garretson	"Medical and Surgical History of the War of the Rebellion," second Surgical volume	Wound of femoral vein	Double ligature of femoral vein; single ligature of femoral artery	Death
Leale	Ditto	Gunshot-wound of femoral vein and prostate	Compresses	Death on the 13th day
Pegue	Ditto	Gunshot-wound of femoral vein	—	Death on the 17th day
—	Ditto	Gunshot-wound of femoral vein	—	Death on the 18th day
—	Ditto	Wound of femoral vein	—	Death
—	Dr. Lidell, *op. cit.*	Wound of femoral vein and crural nerve	Compresses and styptics	Death
Agnew	Quoted by Lidell	Wound of femoral vein during ligature of artery for aneurysm	Ligature of artery	Recovery
Travers	"Surgical Essays," by Cooper and Travers	Wound of femoral vein during ligature of artery for aneurysm	—	—
Gensoul	Quoted by Nicaise	Gunshot-wound of middle of thigh, fracturing femur; secondary hæmorrhage from femoral vein	Ligature of common femoral artery	Death on the 7th day; no gangrene
Desprès	Quoted by Nicaise (*Soc. de Chir.*, Oct. 18th, 1871)	Wound of upper part of thigh; secondary hæmorrhage	Ligature of femoral vein	Recovery
Nelson	"Medical and Surgical History of the War of the Rebellion," Part 3rd	Gunshot-wound of groin; sloughing; pyæmia; secondary hæmorrhage from a wound of femoral vein by a needle	Ligature of femoral artery	Death
—	"International Encyclop. of Surgery" (Dr. Lidell), vol. iii.	Wound of femoral artery and vein	—	Death in a few moments
	Ditto	Wound of femoral artery and vein	—	Death in a few moments
Rose	Ditto	Punctured wound of femoral artery and vein	Double ligature of femoral artery and vein	Recovery
—	Dr. Lidell's article, *op. cit.*	Gunshot-wound of femoral artery and vein	Ligature of femoral artery and vein	Gangrene; death
Dougherty	"Medical and Surgical History of the War of the Rebellion," second Surgical volume	Gunshot-wound of femoral artery and vein	Double ligature of femoral artery and vein; amputation	Death
—	Ditto	Wound of femoral artery and vein	Amputation	Pyæmia; death
—	Ditto	Wound of femoral artery and vein	Amputation on ninth day	Death
Thomson	Ditto	Wound of thigh; secondary hæmorrhage	Ligature of femoral artery and vein	Gangrene; death
Thomson	Ditto	Wound of femoral artery and vein	Double ligature of femoral artery and vein	Death
Gayet	Quoted by Nicaise	Wound of femoral vein and profunda artery	Lig. of external iliac artery	Death

Digitized by Google

bichloride of mercury (1 in 2000), and was closed with catgut sutures, a drainage-tube being inserted at the lower angle, and dressed with sal alembroth wool. A flannel bandage was rolled around the limbs, and the man was returned to bed with the knee slightly flexed. A quarter of a grain of morphia was given hypodermically.

Oct. 12th.—Next morning he appeared comfortable; pulse 96; temperature 98·4°; sweating freely. The leg and foot were nearly as warm as the other side, and there was no œdema. The temperature rose in the evening to 101·2°; and the urine was drawn off by catheter, as none had been passed.

13th.—Temperature 103·6°; pulse 100; profuse sweating; patient restless at times. One grain of opium was ordered every six hours. The wound was dressed; there was no redness of the edges, swelling, or bagging. The drainage-tube was removed. At 9 P.M. the temperature was 104°, and, as the bowels had not acted, an ounce and a half of compound senna mixture was given.

14th.—Temperature 101°. Bowels acted five times during the night, and this diarrhœa continued through the day, in spite of the opium which was taken. There was slight œdema of the left foot and lower part of the leg.

15th.—Temperature 101°; pulse 108. Diarrhœa has ceased. The wound was dressed, and a considerable quantity of turbid serum oozed from it. The highest two stitches were removed, the edges separated, and the cavity was well washed out with corrosive sublimate solution (1 in 2000).

16th.—Temperature 100°; pulse 96; no sweating. On removing the dressing the edges were found sloughy, so the remaining stitches were removed, the edges separated, and the part well irrigated with corrosive sublimate.

17th.—Delirium set in; at 12 noon he had a fit, being seized with tremors and cough, followed by dyspnœa, the patient with wide-open mouth gasping for breath for four or five minutes. The wound was dressed and well irrigated. One-sixth of a grain of morphia was injected, but he slept only a very short time after it, and at night a mixture containing half a drachm of bromide of potassium, one scruple of chloral hydrate, and fifteen minims of tincture of hyoscyamus was ordered to be given every hour until sleep was obtained. The delirium was closely like delirium tremens. Four doses of this mixture produced no effect, and the man had a very restless night. At 4 A.M. one-sixth of a grain of morphia was again injected under the skin.

18th.—The patient has had two hours' sleep, and is much more sensible. The wound looks healthier. During the day he had three injections of one-sixth of a grain of morphia.

19th.—He had had a fairly good night and was better; the edges of the wound were granulating. He was quiet all through the day, and took nourishment well.

20th.—The improvement continued; in the evening he passed urine voluntarily for the first time.

At 12.30 A.M. on the morning of Oct. 21st, after a violent fit of coughing, profuse hæmorrhage came on, and a good deal of blood was lost before aid arrived. The artery was controlled above Poupart's ligament, and Mr. Livermore seized the bleeding point with pressure-forceps. I was sent for, and had the patient placed under the influence of chloroform. I found that the bleeding came from the common femoral artery; without difficulty I placed a silk ligature upon the vessel close below Poupart's ligament. The vessel was softened, and obviously unfit for a ligature as far down as the origin of the profunda, so a ligature was placed around both the superficial and the deep femoral arteries; this entirely arrested the hæmorrhage. The wound was again irrigated with the mercury solution, and dressed as before with alembroth wool. The limb was wrapped in a thick layer of cotton-wool, and hot bottles were placed in the bed.

The patient never recovered from the effects of the loss of blood, and he died in the evening of Oct. 22nd. During the last five days of his life the foot and leg became more œdematous, and especially was this so after the second operation. The foot and leg did not regain their warmth after the ligature of the artery.

The necropsy was made nineteen hours after death by Mr. Roger Williams. Rigor mortis was present, and the body was jaundiced in appearance. The two ends of the femoral artery were separated by about two inches, each secured by a ligature; in the upper end was found a rather firm reddish clot, which extended up to and obliterated the origin of the deep epigastric artery; the distal end was filled by a much smaller and softer clot, about three inches long. The tied end of the profunda femoris artery was found between the ends of the femoral artery. The upper end of the femoral vein was found with its ligature lying loose by it; there was no ligature over or near the distal end. A ligature was found around the internal saphena vein, and another around the external circumflex vein. The profunda vein entered the lower end of the femoral vein. There was a broken-down clot filling the external iliac vein from the entrance of the circumflex iliac vein and extending almost up to the vena cava. The left lower limb was deeply congested, and swollen from œdema and gas generated by decomposition. Liver and kidneys fatty. The spleen weighed 14½ oz., and was deeply congested. The endocardium on the right side of the heart was stained red.

Remarks.—I would submit the following interpretation of this case:—The wound of the vein was made with an infected knife. Antiseptic irrigation failed to remove all the infective material, which, remaining behind, set up inflammation in the wound and led to the breaking down of the thrombus in the vein. The femoral artery may have been bruised at the time of the original injury, although it showed no signs of it at the time, and the treatment pursued—plugging the wound, &c.—may have injured it, and so its walls quickly yielded to the septic processes in the wound, and secondary hæmorrhage ensued, necessitating ligature of arteries. Meanwhile the septic thrombus had been spreading up the iliac vein until all the direct channels for the venous blood returning from the lower limb were blocked, and with this moist gangrene occurred, its full development being prevented by the death of the patient from general blood-poisoning, accelerated by loss of blood.

The consideration of this case naturally divides itself into two heads—the occurrence of the septicæmia and the proper treatment of a wound of the common femoral vein.

1. *The septicæmia.*—Of the fact of septic infection of the wound, with the formation of a spreading, softening thrombus in the iliac vein, there can be no doubt; but exactly to determine how this infection was occasioned is a more difficult matter. My own impression is that the cat's-meat knife was the carrier of the infection, and that my antiseptic irrigation, although carried out with a special view to this contingency, failed to remove all the infective material. All the usual precautions in wound treatment were adopted: the ligatures were of silk, which had been boiled in carbolic acid solution (5 per cent.), and kept in the same liquid. To the occurrence of this septic infection of the wound the fatal result is due, for it prevented the healing of the wound by first intention, was an important factor in the production of the secondary hæmorrhage, led to the complete closure of the channels for the venous return from the limb, and induced the constitutional change which was manifested by fever, sweating, diarrhœa, delirium, and jaundice.

2. *The treatment of the wounded vein.*—From the "Medical and Surgical History of the War of the Rebellion," Dr. Lidell's article in Ashhurst's "International Encyclopædia of Surgery," and Nicaise's "Thesis," I have collected the following cases of wounds of the femoral vein. The cases in the accompanying table (page 259) illustrate several varieties of wound of the femoral vein: (*a*) wound of the vein during the removal of tumours, four cases, all ending in recovery; (*b*) accidental wound of the vein by bullet, sabre, hook, or fragment of bone, eleven cases—only three of these patients escaped with their life; (*c*) wound of the femoral vein during ligature of the artery for aneurysm, two cases; (*d*) secondary hæmorrhage from the femoral vein, three cases, one of which recovered; (*e*) simultaneous wound of the femoral vein and the femoral or profunda artery, ten cases, with only one recovery. As in so many other statistical inquiries the cases have varied so much in their nature, and in some instances the reports are so scanty, that this table cannot be relied upon as a safe and sufficient guide to the treatment of a wounded femoral vein. But at the same time it shows certain facts, the most striking of which is the variety of treatment that has been adopted, and the success that has attended almost every means used.

Ligature of the wounded vein.—The table shows four cases, in one of which the ligature was applied laterally; all these patients recovered, and no mention is made of subsequent œdema or congestion, still less of gangrene. On the other hand, Verneuil is quoted by Nicaise as having had three cases of lateral ligature of the femoral vein, all fatal. During the removal of cancerous glands from the groin on one occasion I had to tie the saphena vein at its juncture with the femoral vein. The man recovered, without any symptom referable to venous obstruction. In

Digitized by Google

M'Clellan's case of lateral ligature of the vein, he speaks of the wound as a large one. The relative value of the lateral and circular ligature is the same in the femoral vein as in other situations, and although many cases of successful lateral ligature of large veins are recorded, the fatalities are too numerous to warrant its repetition, except in the case of punctures and small wounds.

Ligature of the femoral artery.—The table shows in all six cases, three ending in recovery, and three in the death of the patient. The best known case is that of Langenbeck, who failed to secure the vein, and then, on ligating the artery, found the venous hæmorrhage stop. In one of the cases the ligature was placed upon the external iliac artery.

Ligature of the femoral artery and vein.—This was done in three cases for wound of the femoral vein only (including one case of wound of the ending of the saphena vein), with two recoveries; and in four cases for simultaneous wound of the two vessels, with one recovery and three deaths. The ligature of an artery for wound of the corresponding vein was first done by Gensoul in 1831; but Langenbeck's name is specially associated with this form of treatment, which has been advocated also by Tillmanns and others. Langenbeck urged that the danger of ligating the main vein of a limb was the occurrence of gangrene from venous obstruction, and that by tying the main artery the supply of blood to the limb was so reduced that this danger was obviated. There are two sufficient answers to this argument: in the first place, it has been shown that ligature of the main vein of a limb does not produce gangrene so long as the various accessory channels of venous return are patent; in the second place, ligature of an artery lessens very materially for a time the *vis a tergo* of the blood in the capillaries and veins, and therefore reduces the force which is opposed to the venous obstruction. I have three times ligatured the axillary vein while removing malignant growths from the axilla, and have not observed any serious effects upon the circulation, and many cases might be quoted to show that Langenbeck over-estimated the injurious effects of ligature of the main vein of a limb.

The treatment of a wound of such a large vein by compression is not to be recommended, especially in view of the fact that the hæmorrhage, when apparently stayed, is liable to burst out during any expiratory effort, as was the case in my patient. Ollier's case, in which the only treatment adopted was suture of the skin wound and light compression, is a very striking one, and may serve as a good example in like instances.

The best treatment, therefore, appears to be the ligature of the wounded vein, and should I meet with another similar case this is the practice I am prepared to follow. When the secondary hæmorrhage occurred, the question of amputation suggested itself, but such a course would have been quite unjustifiable in view of the success which has sometimes attended ligature of the femoral artery and vein. In my case it would have been doubly wrong, for it would have inflicted a most serious injury upon a patient already doomed to death from the septic thrombus in his iliac veins. In a table of cases of hæmorrhage from veins in the "Surgical History of the American War," fifteen cases of wound of the femoral vein are mentioned, of which only two recovered.

SOME CONSIDERATIONS IN REGARD TO THE CAUSATION OF SEX.

BY A. J. WALL, M.D. LOND.,
H.M. INDIAN ARMY.

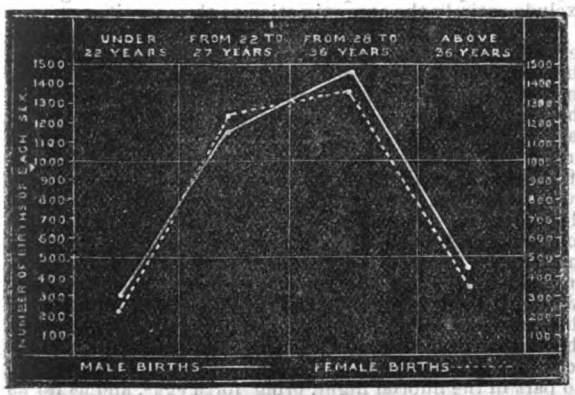
So many theories have been put forward as to the causation of sex that it would require much time even to state them. The object, however, in view at present is to propound no theory whatever, but simply to examine facts that may have a bearing on the subject, and, if possible, to bring out any relation that may be found to exist between the occurrence of sex and any well-ascertained circumstances in regard to the parents, and to draw therefrom any conclusions that may seem just.

In the lower animals there are so many different arrangements of the procreative process that it is not easy to determine what is the exact relation they bear to sex as seen in the higher members of the animal series. Of course, the essential point in all reproduction is the same—namely, the separation of a portion of the tissue of an organism, and its development after more or less change—a change sometimes so great as to surpass the creations of a fairy tale—into an organism like that from which it took its origin; and though in by far the greater number of animals the process has become modified, so that portions of tissue of two organisms unite before development proceeds, yet that it took its origin in the simpler method is evident from the fact that even so high up in the animal scale as birds the first step in the development of the ovum—cleavage—may occur without any interference of the male element whatever, though the process continues no further: a survival of great importance as evidence of an earlier and simpler method of reproduction. But, judging from the facts that intermediate between the simplest forms of reproduction and the complex ones, in which two individuals are required, there is a large class in which both sexual elements are placed in one individual, though not necessarily for self-impregnation, and also that even in the highest animals there is an occasional natural effort to revert more or less completely to this arrangement, it would seem that sex is merely an abortion of one class of sexual organ in each individual, and we must therefore look upon the sexual form which accompanies this as purely secondary. And widely different in appearance as the sexes in the higher animals often are, yet but remove the sexual organs and you have in each case a being with characteristics between the two. Moreover, if there is any imperfection in the development of the sexual organs, there is generally an approach in outward characteristics to the appearance of the other sex, showing that it requires the presence in perfection of one class of organ to exclude entirely the approximation to the opposite sex.

But the mode in which this suppression of one class of sexual organ has been brought about is exceedingly obscure, though a very cursory glance at the animal world would suggest that it is not always produced in the same way. In the class Insecta, for instance, we have in the well-known case of the honey-bee perfect females and sterile females produced from eggs impregnated by the male, but the larvæ of which are fed in different ways; whereas males are produced from eggs that have never received any of the male element at all—a position proved by the fact that if the communication with the spermatheca in the queen be interrupted, the ova then produced only bring forth males, and also that when the common bee is crossed with the Ligurian, only the queens and workers have any trace of the cross-breeding, the males being purely of the race of the queen from whom they proceed. In ants also it occasionally happens that the workers, who of course take no part in the nuptial flight, bring forth eggs, and as far as observation goes—certainly in Lasius niger and Formica fusca—these eggs invariably produce males. Now, whatever views may be held as to the cause of sex in man—and many of them are sufficiently eccentric,—no one has ventured to suggest that it is due to the absence or presence of impregnation by the male element. But even in the same group of animals sex is not always arrived at in the same way, for in this very class Insecta—in Chermes abietis for example—no male individuals have ever been detected, and perfect females lay eggs from which only females are produced. In aphides, again, after several generations of sexless forms, perfect males and perfect females are produced for normal sexual reproduction. In looking, therefore, for the cause of sex, we should be even more careful than usual in not generalising too hastily, and any evidence obtained should be applied in reasoning strictly to the group from which it comes till other observations show that it may be safely extended.

As in man differentiation of sex occurs by no means late in fœtal life, attention is naturally directed to the condition of the parents, and though we cannot with any prospect of success investigate all the circumstances relating to them, yet there is one fact often ascertainable with precision, and that is the age, which is necessarily correlated with some of the most important conditions of life. It will be, then, the present object to examine all the evidence accessible on this subject, and to see what light is thrown on the occurrence of sex; but it may be well to state at the outset that age *of itself* cannot be the cause, for both sexes appear to be produced at nearly all possible ages of the parents.

In regard to man, the examination of this question has not attracted the attention it deserves. Sadler, in his "Law of Population" (vol. ii., page 343), gives a table by which



Digitized by Google

he believes he proves that the older the male the greater is the proportion of male births; but as he admits that in only 381 families were the ages of both parents known to him, and as he classes together all offspring at whatsoever ages of the parents they may have been produced—a proceeding that will be seen in the sequel to be well adapted for defeating the purpose of the examination,—his conclusions are not worthy of serious consideration.

As this inquiry must be necessarily statistical, the first point to be aimed at in the statistics is their accuracy. Therefore, the Royal Houses of Europe were first included. They contributed in all 120 families, our own Royal Family giving 15 of them. The authority chiefly used was the well-known "Almanach de Gotha," and from the same source were taken 27 other families of princely rank. No family was utilised except those in which the dates of the births of both father and mother were exactly given. Next follow 890 noble English families from the "Peerages"—the volumes used being twenty-five years apart in date, so as, if possible, to include two generations. In addition, 163 families are taken from the "Gothaisches Genealogisches Taschenbuch der Gräflichen Häuser." These families had each of them several children, and the mother's house was given in the volume as well as the father's, ensuring, as far as possible, the accuracy of the date of her birth. Thus in all there are 1200 families with 6529 children, being 5·4 children to a family. Of these 6529 children 3381 were males and 3148 were females, or a birth-rate of 107·4 males to 100 females. This is something higher than the usual

CHART 1.

Ages of Mothers.

Showing the number of male and female births at different periods of the ages of the mothers.

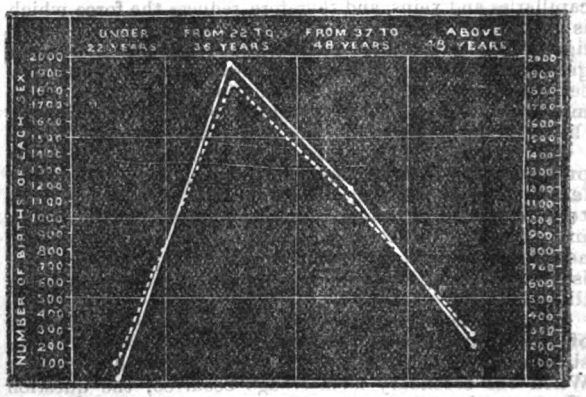
rate, which is generally given as 106 males to 100 females, but variations occur, and a much higher male birth-rate than this has been observed.

As the sexual life of the female is so much shorter than that of the male—being in these statistics thirty-four years, the earliest age of a mother being sixteen and the latest forty-nine,—it will be advantageous to consider first the influence of the age of the mother. Does, then, this proportion of 107·4 males to 100 females obtain equally in all periods of the mothers' lives? To ascertain this it will be convenient to divide the whole time of fertility in the female into periods corresponding to the natural stages of life. The earliest period, that of immaturity, may be taken as commencing from the date of the first birth at sixteen years of age till the completion of the twenty-first year. Within this period there were 589 births, of which 315 were males and 274 females, or a birth-rate of 114·9 males to 100 females—a great excess of male births over the average of 107·4, which occurs at all ages.

The next natural period is that of complete womanhood, when the sexual powers are at their height, which may be taken as from twenty-two to twenty-seven years, both years being included. During these years 2275 births took place, of which 1128 were males and 1147 females. This is equivalent to a birth-rate of only 98·3 males to 100 females—a very complete reversal of the usual frequency of the occurrence of the sexes.

After this the sexual powers undergo a decline, but it will be convenient to divide the remaining sexual life into two periods using the end of the thirty-sixth year as the dividing line. From the twenty-eighth to the thirty-sixth year inclusive 2823 children were born, giving 1489 males and 1334 females, or a proportion of 111·6 males to 100 females. Here the males again asserted their predominance considerably beyond the mean proportion.

The last period will be from the thirty-seventh year to the termination of sexual life at forty-nine years. Here 842 births occurred, of which 449 were males and 393 females, being 114·2 males to 100 females—a very great excess of male births, being only a fractional part below the excess noted in the period of immaturity.



There is, therefore, evidence that the proportion between the male and female births is constantly changing, and that the varying proportion bears a distinct relation to the sexual condition of the mother. Chart 1 will show more clearly than any words this relation between the age of the mother and the sex of the offspring.

We must now turn to the influence of the age of the father. But we have here a difficulty to contend with, which is due to the much greater length of the sexual life of the male. In the tables containing these statistics the age of the youngest father is nineteen, and the oldest eighty, giving a sexual life of sixty-two years. To investigate thoroughly an extended period like this would require a far larger number of families than is at present available.

In the period of immaturity in the male, which may be taken, as in the female, up to the end of the twenty-first year, there were but 24 births, of which 10 were male and 14 female, or a proportion of only 71 males to 100

CHART 2.

Ages of Fathers.

Showing the number of male and female births at different periods of the ages of the fathers.

N.B.—In this chart the dotted line begins too far above the plain straight line. The two ought to begin very close together, the dotted line being only slightly above the other.

females. This, taken together with the evidence we have obtained from the mother in the time of immaturity, when no less than 114·9 males were born to 100 females, shows how little capable the immature parent is of impressing its own sex on the offspring. But it shows, moreover, that the immature male has even less power of doing this than the immature female.

After the twenty-second year a difference is perceptible in the influence exercised by the male and female parent. In the female from twenty-two to twenty-eight years a considerable excess of female births takes place; but after that there is a decided decrease; whereas in the male there appears to be no great difference in the proportion of male to female offspring till considerably after thirty years. Thus from twenty-two to thirty-six years of age, both inclusive, of the fathers, there were 3820 births, of which 1997 were males and 1823 females, or 109·5 males to 100 females—an excess of males beyond the mean proportion.

In the period from thirty-seven to forty-eight years there were were 2281 births, with 1180 males and 1101 females, or a proportion of 107·1 males to 100 females, or a slight decline of males from the previous rate, and very close indeed to the mean proportion.

In the last period, that of decadence of sexual power, from forty-nine years to the limit of sexual life, here given at eighty, there were 404 births, with 194 males and 210

Digitized by Google

females, or a proportion of only 92·4 males to 100 females. That is to say, in the period of declining sexual power in the male the proportion of females born is greater even than at the period of the greatest energy of the female, from twenty-two to twenty-seven years. At the same time, the proportion of males produced by male parents in their declining years is considerably greater than at the age of their immaturity. Chart 2 illustrates these varying proportions.

(To be concluded.)

ON A CASE OF

INCISION AND FREE DRAINAGE OF THE LUNG FOR PHTHISICAL CAVITIES.

BY ARTHUR NEVE, F.R.C.S. EDIN., &c.

IN the very dawn of surgery it is probable that the chest was opened from time to time when abscesses pointed outside it. In this sense "pulmonotomy" is no new proceeding. But incisions through the thoracic wall for gangrene, deep-seated abscess, and bronchiectasis or tubercular cavity are truly modern operations, differing from the former as widely as the counter-puncture and thorough drainage of an abscess differs from the rude gash made by some Polynesian savage. The advance of visceral surgery has, indeed, only been rendered possible by the increased precision of diagnosis; and there is little cause for boasting of surgical advance, when in such a large proportion of cases the increased accuracy of diagnosis only makes us feel the more keenly our remedial powerlessness. It is only within quite recent years that notices of attempts to drain purulent collections in the lung itself have appeared in the journals. As far as I can make out, from reference to Dr. Neale's valuable Digest and the medical journals, the cases as yet are confined to one or two for abscess, several for gangrene, and more recently one or two for bronchiectasis. But that the operation has not taken a recognised position is shown by the fact that in Quain's "Dictionary of Medicine" it is only mentioned in connexion with gangrene, and then but casually as an alternative of tapping. The case which I have to record is as follows:—

A young man, haggard and wasted to a degree, was admitted into the C.M.S. Mission Hospital on April 10th, 1886. For a year he had been suffering from violent cough and profuse expectoration. His appearance was that of a man in the last stage of phthisis. His fingers were much clubbed. The expectoration amounted to a pint and a half or two pints in the twenty-four hours. It was tough, and in large flocculent, purulent masses. Microscopic examination showed a very considerable proportion of pus cells, with elastic fibres, &c., and swarming with bacilli. Examination of the chest revealed the presence of cavities in the upper and anterior part of the right lung, while the right base and most part of the left lung was fairly healthy. The left apex appeared condensed, with possibly commencing softening. For nearly three weeks the patient was treated with cod-liver oil, tonics, eucalyptus and creasote spray, and counter-irritation. During this time there was no improvement, and the patient (a troublesome one) was clamorous for something to be done. Accordingly on April 29th, having administered chloroform, I made an incision two inches long close to the right nipple, through which a corresponding portion of the fourth rib was resected, with the periosteum attached. The pleural surface was, as I expected, firmly adherent. I then forced my finger inwards and upwards in the direction of the cavities. There was no such large cavity close to the wound as I had hoped to find; but upwards it entered two small cavities. The tissues were hard, but friable. I did not attempt to open the cavities on the axillary side, deeming that they would drain by the bronchi into the wound. A large-sized drainage-tube, six inches long, was passed into the lung, and the wound closed by a pad of gauze and a sawdust bag. Hæmorrhage was quite inconsiderable, and the air whistling through the wound gave promise of good drainage. Within two days the expectoration by the mouth was diminished to three or four ounces, and was no longer accompanied by the distressing cough which the man had complained of. There was, however, much pain about the wound. It was daily washed out with corrosive sublimate solution, and pure oil of eucalyptus was poured into the tube. At first this gave rise to cough, but tolerance was established. Inhalations of creasote and eucalyptus were continuously maintained by keeping the pad on the wound moist with them. The discharge from the tube was chiefly muco-purulent; at first bloody, later thick and tenacious, but progressively less so. About the fourth week the patient began again to complain of the drainage-tube (which he had himself removed several times during the first two days); a little blood also appeared on the dressings; so, fearing ulceration into the vessels of the lung, I removed it altogether. In the early part of June the sputum continued healthier, and he went home. On the 24th he returned. The improvement was then striking, especially in the local signs. The chest around and above the wound was considerably contracted, and sucked in. The sinus was freely open, and upon coughing some mucus was expelled from it. The healthy area of the lung seemed increased. The apex of the left lung, however, showed more signs of breaking down. He remained under observation in hospital for two days, and was photographed. The expectoration was about ten ounces in twenty-four hours, but was chiefly clear and watery, with a few nummular masses similar to those of which it formerly entirely consisted. His cough troubled him only in the morning; he slept and ate well, almost ravenously, and gained strength, though but little flesh. He was then sent to a mountain sanatorium 8500 feet above the sea. Up to this point the improvement effected was entirely by means of the operation. Since that time I have not seen the patient, but occasionally receive reports from his friends. After September he became weaker. He is said to wander over the country, is seldom at home, and does not work. There still remained a small opening in the chest.

Remarks.—In resorting to pulmonotomy for a case of advanced phthisis, I was performing an irregular proceeding, though it was fully justified by the amount of the expectoration, by the limitation of gross lesions to one lung, and to a not very extensive area therein, and, therefore, by the possibility of effective drainage. An operation, moreover, offered the means of directly medicating the affected parts, and of delaying or arresting the advance of disease in the other lung, which would have rapidly determined a fatal issue. For these reasons I did not hesitate to avail myself of the willingness of the patient to undergo an operation which he was given to understand would alleviate his distress. The result was as satisfactory as I had anticipated. The cavities which were opened, and also those higher up in the apex, ceased to secrete such a large amount of sputum, and apparently cicatrised. In this they were assisted not only by the drainage and topical medication, but by the removal of a considerable portion of rib, with the consequent possibility of retraction of the thoracic wall. The slight amount of respiratory movement of the upper part of the chest and lung is probably the chief cause of the special liability of the apex to the formation of tubercle and its resulting cavities; but even this slight movement is probably unfavourable to the healing of such cavities when the pleural surfaces are adherent. I therefore think that in many cases of phthisis with apical vomicæ it might be beneficial to remove portions of the upper ribs, as in Estlander's operation for empyema. If a similar case presented itself, but with less abundant sputum, I should be disposed to try the resection of portions of the second and third ribs, with intra-pulmonary injections. As the preliminary to all operative methods, the usual antiseptic inhalations and other remedies should be fully tried. Having decided to operate, the aspirator should be used to confirm the diagnosis as to the position of the cavity. The first risk met with in operating is that arising from non-adhesion of the pleura. Circumstances may point towards adhesions, but the diagnosis must always be attended by uncertainty. Puncture and drainage of a cavity, where the pleural cavity is not shut off from the purulent secretion, would lead almost necessarily to a pyogenic pleuritis. If after resection of the rib the pleura is found non-adherent, it would probably be best to unite the lung by catgut stitches to the thoracic wall, and postpone incision into the lung for a few days, when the exuded lymph will occlude the pleural cavity; this might not be practicable on account of collapse of the lung, but at least it might be attempted by seizing the lung with a sharp hook, and effecting the suture promptly.

Digitized by Google

In making the incision it is not necessary to use a sharp instrument. The friability of the lung often permits of the finger being used, in which case dangers are avoided and information procured which no other instrument could give. In my case bleeding was insignificant, and most surgeons have found that if it occurs it is easily arrested. Drainage takes place less by gravitation than by the expiratory efforts; but position can do much towards helping these. Similarly, position, aided by inspiratory efforts, will effectually distribute antiseptic applications, such as iodoform dust, eucalyptus oil, &c., to subjacent parts of the lung, and their effect may be kept up by the use of volatile antiseptics in the dressing used. As in all my surgical cases for the last four years, I use large pads of cedar sawdust, to which I add creasote &c.; these act as respirators, filtering and warming the air. I may add that the operation cannot be taxed with failure because a permanent cure is scarcely to be achieved, inasmuch as legitimate operative interference is necessarily delayed until the disease has made great headway, and the local symptoms, grave as they may be, are but the manifestations of a graver constitutional disease.

Kashmir Mission Hospital.

CASE OF STRONGYLUS GIGAS.

BY R. CANNON, L.K.Q.C.P., L.R.C.S.I., M.D. CHILI.,
LATE SURGEON, ROYAL NAVY.

ON August 20th I was called to see a boy of twelve years of age suffering from febrile symptoms of three days' duration. He complained of headache, aching in the limbs, and general malaise. He had had epistaxis, his tongue was foul, and his bowels costive; temperature 39·50° C.; pulse 90. The night before I saw him he could not micturate, and on the morning of my visit he had done so without difficulty. In the chamber-vessel, which he had used in the upright position, a worm had been seen. The "patio," or court of the house, was asphalted and dry, and it was quite impossible that any earth-worm could have been introduced by chance into this vessel. I take this to be a case of strongylus gigas, of which only seven cases at all trustworthy have, according to Davaine, been reported. The worm was in three parts, and was of a reddish colour, as if blood-stained. It measured about ten inches. Around the head could be seen prominences, as if tubercles or rudimentary eyes; some fine membranous films, as if of a delicate cyst, were adherent to the broken parts. The urine contained no blood or any deposits; it was of a darkish colour, but not more so than one sees in febrile states. I at once put the specimen into spirit and have not since extracted it, contenting myself with examining it with a lens. It does not appear to me to be an intestinal lumbricus, and I have not the slightest doubt that it issued from the boy's urethra. He was not aware of having passed anything unusual until the vessel was brought to him by his mother. There could be no object in deception of any kind. The boy was treated with salicylate of soda and with nightly doses of antipyrine, and after copious bleeding had taken place from the nostrils the headache and febrile symptoms were in a few days quite relieved, and the boy had no other troubles in connexion with the urinary organs.

We know that this parasite is found in the kidneys and urinary passages of such animals as the weasel, hare, ox, dog, wolf, &c.; but in the present case the only animal that could have interfered would be the dog. I saw no dogs about the "patio," and, besides, it would have been ridiculous to suppose that a dog would have had the sagacity to deposit his strongylus gigas in a chamber-vessel; moreover, on the previous night the boy had been unable to pass his urine, and the parasite must have occupied the urethra or blocked its entrance into the bladder.

Cases have been recorded in which intestinal worms have found their way into the bladder. This, of course, might easily occur in the female, but in the male the difficulty would be great. The boy, in this instance, was a quiet sensible lad, not by any means hysterical or a trickster, and I think the case from its rarity is very interesting and worthy of the fullest investigation. Of course the interest turns on this worm being a specimen of strongylus gigas or not, and this fact I have no means of deciding. I showed the specimen to my friend Dr. von Schroeders, of this city, but he had no plates depicting the parasite. I also showed it to an American colleague, but, curiously enough, he had never heard of such a thing as strongylus gigas.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF EXOPHTHALMIC GOITRE TREATED BY THE CONTINUOUS CURRENT.

BY W. B. HADDEN, M.D., M.R.C.P.

DRUGS are uncertain, and unfortunately often useless, in exophthalmic goitre. I therefore determined to try galvanism in this case, and the result, as will be seen, was very satisfactory.

The patient was a single young lady, aged twenty-eight, a professional nurse. She consulted me on Jan. 15th, 1886. For nine months previously she had found difficulty in distinguishing the names of streets, and for three months her friends had noticed that her eyes were prominent. She had remarked some fulness of the throat for two months. When I first saw her the eyes were markedly prominent and somewhat injected. The thyroid was large, mainly on the right side, but not pulsating. The pulse was 140. There was no cardiac bruit. She had frequent and excessive perspiration. There were constant efforts at deglutition, and she suffered from borborygmi. The bowels were regular. There was no derangement of the catamenia. She expressed herself as feeling pretty well in herself; but on being questioned said she had some dyspnœa and dysphagia. She had never suffered from any illness except measles. I ordered a constant battery of ten cells to be used night and morning. The negative pole was placed on the nape of the neck, and the positive over the thyroid gland and also over the eyeballs, the eyelids being closed. Each application did not extend beyond ten minutes. There was a marked improvement in a month.

On June 22nd she was practically well. The right eyeball and the right side of the thyroid were still slightly full. There was no palpitation, from which previously she had suffered, and the pulse was reduced to 96. The perspiration and sensations of excessive heat had quite disappeared. I have seen her frequently since, and the improvement is maintained. She tells me that when her illness first began she used to sleep in cold weather with only a sheet over her. During the time she was under treatment her weight increased by more than one stone. No medicine was given except belladonna for two or three weeks; but this drug, which was prescribed at the very onset, was discontinued, as no beneficial result ensued. The battery was not used at this time.

Remarks.—The treatment of exophthalmic goitre by this method deserves a trial. I do not wish to dogmatise from one case; but I may mention that I have had quite recently the opportunity of seeing the beneficial effects of the continuous current in another patient.

Welbeck-street, W.

ON A CASE OF TETANUS SUCCESSFULLY TREATED WITH CHLORAL HYDRATE.

By J. HAWKES, M.D.

I THINK the following notes on a case of idiopathic tetanus treated with chloral hydrate throughout the greater part of its duration may prove interesting, as indicating the almost specific effect of the drug and the large doses tolerated in this often intractable complaint.

A healthy country lad, aged thirteen, employed in outdoor work, was taken ill with symptoms of tetanus about a week before my attendance was requested on Nov. 16th. When I saw him he was lying on his back in rigid opisthotonos; dorsal region and thorax prominently arched, and stretched towards the right side; head drawn back; eyelids partly closed: lips retracted, exhibiting marked

Digitized by Google

risus sardonicus; muscles of neck and trunk hard and board-like; lower extremities extended; breathing hurried and shallow. The boy had been unable to sleep. The jaws were firmly clenched to within about a quarter of an inch. I ordered belladonna liniment to the spine, powdered jalap with calomel, and a sudorific mixture three times a day. As he resided at some distance from my house, two days elapsed before I saw him again, when his condition had undergone no change. The bowels had freely acted. Linseed-meal poultices sprinkled with turpentine were applied to the dorsal region, and ten grains of chloral hydrate, with twenty grains of bromide of potassium, were given every four hours.—Nov. 21st: Has had two hours' sleep, the first he has had since the beginning of his illness. Decubitus natural; opisthotonos much relieved, but not disappeared. Countenance natural; lips no longer retracted, but the jaws are clenched as before. To continue treatment, and apply a mustard-and-linseed poultice to the nape of the neck.—22nd: Slight improvement. — 24th: The chloral to be increased to twenty grains and the bromide of potassium to thirty, and taken every four hours. — 27th: Can open his mouth more freely, and speak distinctly, but the rigidity persists in the abdominal and thoracic muscles; the neck is easier. To apply linseed poultice with turpentine to the neck as before. To continue the treatment.—Dec. 2nd: Lies placidly in bed; answers questions distinctly; sleeps for two or three hours, but never more than three; bowels act regularly; takes semi-solid food. To continue the treatment.—6th: Is going on fairly well, but some rigidity continues, especially in the trunk; can move the feet freely. The chloral treatment was now suspended for four days, and henbane with fœtid spirit of ammonia substituted, but no improvement followed.—10th: Ordered fifteen grains of chloral hydrate, twenty minims of tincture of lobelia, and twenty minims of compound tincture of cinchona, thrice daily.—13th: Belladonna plaster applied to the whole dorsal region. To continue the treatment.—17th: Has obtained further relief, the rigidity becoming less. To continue the mixture. Is wearing the plaster, which he feels to be beneficial.—22nd: Is altogether better. To continue the mixture and repeat the belladonna plaster.—24th: Is very comfortable, and almost convalescent.—29th: Was able to enjoy his Christmas dinner downstairs with the rest of his family. Appears to be fairly well. To discontinue the treatment.

Remarks.—This was a case of idiopathic tetanus brought on by exposure to wet and cold. It presented the symptoms of trismus very markedly, and there was absence of sleep for a long time. It appears to me that chloral alone or combined with bromide of potassium controlled the severity of the disease, and if it did not actually cure the malady it afforded time for nature to exert its recuperative power.

Northampton.

SURGICAL MISHAPS.

By E. L. HUSSEY, F.R.C.S.E.

ONE of the cases mentioned by Mr. Teale reminds me of a case formerly under my care.

In 1861 a young lady applied to me with a small tumour behind the angle of the jaw on the right side. It was tough and almost cartilaginous under examination, and the skin was generally adherent over the surface. The case had been seen by the late Mr. Hester and Mr. Owen of Oxford, and by Sir H. Acland. It was thought to be of a cystic nature, and the swelling had been injected with tincture of iodine. I cut through the substance in its whole thickness, and endeavoured to clear away the contents from each half; this could only be done to a very slight extent. The wound healed favourably. A second operation was undertaken some months afterwards. The skin was divided, and separated without difficulty from the tumour. This now appeared to be about the size of a large walnut and of a fibro-cellular structure. I cut off the exposed part, so as to clear the wound for a deeper dissection. Then, fixing a hook in the remaining part, I endeavoured to draw it forwards. This I was unable to do. The attachment was evidently very deep; the skull itself moved with the motions of the hook. I cut off, as deeply as I could, the part of the tumour which was transfixed by the hook, and closed the wound. This healed as favourably as after the former operation. The lady afterwards married, and she died from phthisis more than twenty years after the operation. There was not any fresh growth of the tumour. Being in communication with Mr. Cæsar Hawkins at the time of the operation, I mentioned the case as a disagreeable piece of active surgery. He told me that Mr. Liston, in a similar case, found, upon the death of the patient, that the tumour had its origin in the base of the skull.

Oxford.

HYDATID OF LIVER TREATED BY PUNCTURE; COMPLETE RECOVERY.

By FREDK. A. A. SMITH, M.D.

MRS. K——, aged forty-eight, struck her right side against the kitchen table about five months ago. She did not think anything about the accident, but soon afterwards felt a pain in the right side, which gradually enlarged and extreme emaciation set in. Cancer was diagnosed by several medical men, and one thought the ribs were fractured. When I saw the patient, she was extremely weak and emaciated, and looked like a woman dying of cancer. On examination the ribs of the right side were found very prominent, with bulging of the intercostal spaces. Percussion dulness extended over the median line and downwards to nearly three inches below the ribs. The tumour felt firm and smooth, and gave one the impression of an enlarged liver. At a spot, the size of a florin, an inch below the margin of the lower ribs and two inches to the right of the median line, slight fluctuation was felt. Diagnosing the case as one of either abscess or hydatid cyst, I plunged a No. 1 trocar and cannula into the centre of the fluctuating spot, in a direction upwards and backwards, and drew off about six ounces of limpid, straw-coloured fluid. A small piece of plaster was placed over the puncture and a towel tied tightly round the abdomen. Nothing more was done, and the patient got rapidly well and is still alive. The only precautions I took were to stretch the skin, so as to make the opening valvular and arrest the flow of liquid before the cyst was entirely emptied; thus no air was allowed to enter.

The interesting part of this case was the distinct history of a blow, and the rapid enlargement of the tumour and extreme emaciation. The fluid was examined carefully under the microscope, but no hooklets were detected.

ST. THOMAS'S HOSPITAL.

SUPRA-PUBIC LITHOTOMY IN A MAN AGED SEVENTY-TWO; CURE; SUBSEQUENT DEATH FROM APOPLEXY; REMARKS.

(Under the care of Mr. JOHN CROFT.)

THE following case is one of those in which the operation which was performed is specially advantageous. There were two large stones, an enlarged prostate, and a patient who was in a very poor state of general health. He was not in a condition to bear the prolonged administration of an anæsthetic, or the manipulation which would have been called for had the size of the stones permitted of lithotrity; therefore no very accurate measurement was taken of the stones before operation, the supra-pubic method being so clearly indicated.

J. T——, aged seventy-two, a labourer, was admitted into Edward ward on July 12th. About twelve years ago he noticed pain at the end of the penis on micturating; during the last two or three years the pain has increased. Micturition is and has been very frequent, he not being able to hold his urine for more than two hours. Has on several occasion had catheters passed, but has not suffered from retention of urine. On examination per rectum the prostate

Digitized by Google

was felt considerably enlarged laterally. On passing a sound the sensation of striking a stone was elicited, and appeared to be produced by the presence of a very large one or by a collection of calculi, stone being struck on either side as the sound was rotated. The urine was very offensive, alkaline, and contained pus. The patient was much enfeebled by suffering and age, by degenerated arteries, and a great tendency to bronchitis.

On July 17th Mr. Croft operated. Chloroform was administered. A catheter was with some difficulty passed into the bladder, and this was washed out three times with a solution of boro-glyceride, eight to ten ounces of this solution being left in the bladder, and the rectal bag injected with twelve ounces of fluid. An incision three or four inches in length was made in the middle line above the pubes. There was a fair amount of abdominal fat. The tissues in front of the bladder were unusually friable and vascular, the veins being somewhat varicose in appearance. A puncture was made in the bladder with the point of a scalpel; through this the forefinger of the left hand was inserted and the wound dilated. Two large calculi of lithate of ammonia &c. were extracted, together weighing over four ounces, one weighing 969 grains and the other 945 grains. No other stone was felt, but the middle lobe of the prostate formed a well-marked projection into the bladder. The opening in the bladder was not closed, but two stitches were placed in the upper part of the abdominal wound. The bag was removed from the rectum. A large drainage-tube was inserted, and the wound plugged with lint soaked in carbolised oil; over this was placed lint spread with iodoform and vaseline ointment and finely drawn carbolised tow and absorbent wool. Two hours before the operation the patient had had a rigor, and the temperature rose to 101·4°; in the evening it was normal.

For three days the patient was kept on his back, and a flexible indiarubber catheter retained in the urethra. The wound was dressed every two hours in a similar manner to that employed after the operation. For a long time the old man was very feeble and apathetic, requiring great attention and careful feeding and nursing. The catheter was of no service, and therefore removed.

On the 18th he had slept well after a subcutaneous injection of morphia, but complained of pain in the abdomen due to flatulence; warm milk instead of cold was given, and he was much easier in the afternoon. There was slight cough, and his breath was very offensive.

19th.—Wound washed out morning and evening with a carbolic solution. He perspires very much over the face and hands.

20th.—Restless, requiring the subcutaneous administration of morphia. Complaining of flatulence and cough, he was ordered an effervescing mixture of citrate of potash and carbonate of ammonia, and allowed three ounces of rum.

21st.—Allowed to lie on his side. Had an attack of convulsive character in the early morning, which lasted about fifteen minutes, during which he appeared to be only semi-conscious.

On the 23rd the bowels acted after medicine. The drainage-tube was removed on the 28th, and a sponge, which had been soaked in a warm solution of Condy, was applied over the wound. Wine was ordered, and a tonic of quinine and iron.

There was a gradual but slow improvement until Aug. 1st; during that day he complained several times of faintness and shortness of breath, but could move more easily in bed in the intervals. The urine was very offensive, and most of it came by the wound. Next day a broad strip of strapping was placed across the wound from hip to hip; and in the evening he was taken out of bed, and sat in an arm-chair for a time. The wound was kept open for more than a month after this date, and the bladder washed out daily. The temperature rose on the third day after the operation to 101·6°. This was the highest record, the reading after the fourth day varying from 96° to 98·6°. He was taught to pass a catheter for himself. When he left the hospital, the wound was firmly closed, there was no evidence of cystitis, and the man was apparently quite well.

It appears from a letter written to Mr. Croft by Dr. Thomson of Luton, who attended the patient, that the latter died suddenly on the 19th of October from apoplexy.

Remarks by Mr. CROFT.—This case is of special interest, as it is the first supra-pubic operation for stone performed at St. Thomas's since Cheselden gave up the high operation about a century and a quarter ago. He himself says that "he would not have left the high way but for the hopes he had of a better, being well assured that it might hereafter be practised with greater success." His prediction has come true. The incision into the bladder was a puncture not more than half an inch in extent; this was dilated with the finger until large enough to allow of the extraction of the stones. This lesion healed, when permitted to do so, very soundly and readily, although the exit of urine from the bladder was materially obstructed by the enlarged middle lobe of the prostate, which projected greatly into the bladder. It was only his age and debilitated condition that prevented the removal of this at the time of operation.

BULLET WOUND OF CHEST; WOUND OF LUNG; REMOVAL OF BULLET; RECOVERY.

(Under the care of Mr. CROFT)

BULLET wounds of the chest are not common in civil practice, and it is important that such should be recorded if only to increase our knowledge of the prognosis when they are treated under the most favourable conditions. That there was a penetration of the lung in this patient was proved by the amount of shock which immediately followed the injury, the hæmoptysis, the emphysema which was manifest around the point of entrance and about the swelling behind, which corresponded to this point, by the subsequent slight hæmopneumothorax, and the later development of localised pneumonia. No attempt was made to remove the bullet at first; the amount of shock was considerable, and it was not considered advisable to add to this or increase the risk of septic inflammation of the parts damaged by the passage of the bullet. For the following notes we are indebted to Mr. G. R. Anderson, dresser.

F. de C. C——, aged thirty-three, was admitted on Oct. 12th in a rather collapsed condition, suffering from a gunshot wound of the chest, of his own infliction. He used a five-chambered revolver, carrying a ·320 bullet. Before using it he threw back his coat and vest.

On admission the patient was pale; surface of body and extremities cold; beads of perspiration on the forehead; hands clammy. The pulse felt at wrist was rapid, thready, and small; respiration shallow. He spoke rationally and answered questions; seemed in a desponding condition, and expressed a wish to die. On examination, in front was found a small wound in the second intercostal space, on the left side, just internal to the nipple line. The shirt covering this region was blood-stained, blackened, and singed round a small hole corresponding to the wound. The patient wore no under-vest. On probing the superficial part of the wound the direction was found to be from before backwards and outwards. No rib was exposed. The tissues round the wound were emphysematous. On forced respiration this emphysema was increased, but air did not definitely escape by the wound. On examining the back, a small hard body was found over the vertebral border of the scapula about an inch and a half from the root of the spine, freely movable under the skin; some tenderness on moving it. There was emphysema about this also. The wound was dressed with carbolic solution (1 in 20), and a pad of iodoform gauze strapped firmly on. Mr. Croft saw the patient at 10.30 P.M. He had rallied from the shock. There had been very little external hæmorrhage, but there were signs of internal bleeding. Bright-red sputa. Dulness over left base behind; hyper-resonance in front. Emphysema was now detected as low as the pubes, extending backwards over the left loin; it also extended some little distance up the neck. It was not largely increased over the scapular region. Mr. Croft decided not to remove the bullet at once. The patient was given ice to suck, and the front and left side of the chest were covered with ice-bags.

Oct. 13th.—Retention came on; bladder emptied by catheter at 9 P.M. Some cough; bright-red sputa. Temperature 100·4°; pulse 82; respiration 36.

16th.—Some dyspnœa early this morning. Sputa merely blood-stained. Bullet wound has healed without suppuration.

17th.—Patient sleeps badly. No recurrence of dyspnœa. Catheter passed every eight hours. Temperature 98·8°.

18th.—Cough better. Sputa streaked with blood. Ice-bags discontinued. Temperature 98°; pulse 72; respiration 36.

20th.—Has control of bladder. Emphysema remains. At

Digitized by Google

the right base posteriorly, dulness, tubular breathing; and crepitations; above the left base also there is a small patch of pneumonia. Pulse 90; respiration 28; temperature 100·4°.

22nd.—Patient feels comfortable. Cough better. Temperature 98°; pulse 85.

26th.—Sleeplessness returned. Pulse 80; respiration 24.

29th.—Cough almost gone; no blood in sputa since the 15th.

Nov. 1st.—Mr. Croft removed the bullet; subcutaneous injection of cocaine (1 in 20) was given ten minutes before extraction. An incision of an inch and a quarter was made over the bullet; it was found to be beneath the muscular fascia; this was incised and the bullet withdrawn without difficulty; wound dressed antiseptically. The bullet was grooved on one side in screw-like fashion, flattened at the apex; on comparison with an unused bullet it was six grains short.

3rd.—Wound dressed; looking well. Temperature 97·4°; pulse 80.

10th.—Patient got up to-day; feels much better. Wound dressed with chlorinated soda solution three times daily.

20th.—Emphysema over abdomen, chest, and neck quite gone. Wound nearly healed; some swelling and hardness to left of incision still remains.

22nd.—A little suppuration in the wound; a drainage-tube put in.

25th.—Discharge decreasing; wound syringed out with weak solution of chlorinated soda solution.

Dec. 2nd.—Patient went out, there being still a little discharge from the wound. His mental condition has improved since admission, though he is still very desponding at times.

Jan. 31st.—Continues quite well.

LEICESTER INFIRMARY.

SUPRA-PUBIC LITHOTOMY IN THE ADULT; SUTURE OF BLADDER; PRIMARY UNION; REMARKS.

(Under the care of Mr. C. J. BOND.)

W. C——, aged forty-nine, blacksmith, very stout. Has had symptoms of stone for three years, also some enlargement of the prostate, the bladder being very irritable. At the time of operation the bladder was emptied and injected with sixteen ounces of boracic fluid, and the rectal bag then introduced and distended. On division of the abdominal wall, the bladder did not seem fully distended, so four ounces more were injected, and it was then opened in the usual way. A uric acid calculus, measuring 1½ in. in one and 1¼ in. in the other diameter, was removed by lithotomy forceps. Catgut sutures were used, the upper being passed first through the bladder muscular wall, slightly inverting the edges of the wound; the organ was then held up by this suture, and the others introduced. A drainage-tube was placed deeply in the abdominal incision, and the bladder again injected with boracic fluid, which came out clear. No catheter was left in, but a soft catheter was passed every three hours for the first two days, the patient passing urine naturally on the third day. On passing the catheter, however, on the evening of the day of operation, the bladder contracted violently, forcing the catheter out and driving some urine between the sutures through the wound. This, however, did not occur again, and apparently did not retard the primary union of the bladder wound at all. The drainage-tube was removed on the fourth day, the wound having healed. The temperature was normal throughout.

The supra-pubic opening was chosen in this case, on account of the enlargement of the prostate, the great depth of the perineum, and the irritability of the bladder.

Remarks by Mr. BOND.—This is, I think, a good example of primary union of the bladder wound after supra-pubic lithotomy in the adult, and the result is the more encouraging, because it shows that an escape of urine between the stitches within a few hours after the operation need not necessarily prevent union, provided *that the urine be healthy* and there be no cystitis with its accompanying urinary decomposition. I think it might be useful in the present probation stage of this operation to draw attention to the following points:—First, the difficulties of suturing the bladder in a fat adult, with large pelvis and stout abdominal muscles, are considerable, but can be best overcome by inserting the upper suture first, pulling the bladder upwards by this, and so drawing the edges into apposition; the bladder wall being thick, it does not seem necessary to produce much incision of the edges, but chiefly to avoid transfixion of the mucous membrane. Secondly, after considerable or even moderate distension of the bladder when the tension is relieved by the incision and rapid escape of fluid, the organ does not contract at all forcibly for some little time, but rather collapses; the posterior wall is driven downwards and forwards by the weight of the abdominal viscera on to the anterior, thus flattening the empty viscus; and unless the finger is introduced immediately after the incision, this bulging forwards of the posterior wall may render manipulation inside the bladder more difficult, and might possibly lead to injury if the point of the knife be held directly backwards. A slight difficulty was also caused in the case related by the rectal bag being introduced *after* injection of the bladder; it thus slipped up the bowel and, passing above the sharp peritoneal fold (which can always be seen like a broad ligament on looking into the pelvis), turned forwards and increased the bulging of the posterior wall mentioned above. In the distended bladder in the living and in the dead subject, as the peritoneum is pushed or rather drawn upwards it leaves an empty fold in the angle between the abdominal wall and the receding upper part of the anterior surface or summit of the bladder; this upper portion of the anterior surface is never wholly uncovered by peritoneum by distension, and the fold mentioned above is generally pulled upwards out of the way at the operation. The uncovered space in a distended bladder has, in fact, the shape of a triangle with apex cut off, with the base downwards on the pubes, its width here corresponding to the interval between the two Poupart's ligaments. Finally, in settling the important question whether after supra-pubic lithotomy the bladder wound should be left open and a tube placed in the bladder, or whether it should be sutured and primary union attempted, I think the condition of the urine may be a guide; if that be healthy, other things being equal, primary union will probably result after careful suturing; it seems better to pass a catheter frequently than to leave one in the bladder.

ST. VINCENT'S HOSPITAL, DUBLIN.

A CASE OF PERFORATING ULCER OF THE STOMACH.

(Under the care of Dr. QUINLAN.)

B. O'C——, aged thirty-eight, cook, was admitted on Oct. 11th, in great agony. She had for several years been suffering from dyspeptic symptoms, with occasional gastric irritation and habitual constipation, for the relief of which she constantly took purgatives. On the previous Wednesday night she had taken pills and a large dose of compound senna mixture, which had a powerful effect. Immediately after she was attacked by severe pain, which kept increasing. Early on Saturday morning the pain became intolerable, and her employer humanely called in Dr. Kendal Franks, who saw her immediately, and to whom I am indebted for the notes of the case while it was under his care. Dr. Franks found her in acute agony and resting upon her elbows and knees. With difficulty getting her to lie upon her back, he found slight distension of the abdomen, but no pain on pressure worth recording. The pulse was 110, the temperature normal, and the expression of the face pinched. She became worse and worse, with increasing temperature, and was removed to St. Vincent's Hospital on the Monday. The abdomen was then greatly distended, but there was no pain on pressure; in fact, pressure seemed rather to give relief. There was much vomiting, and nothing would remain in the stomach except a little iced brandy-and-water. Her bowels had not moved since the previous Thursday; the pulse was 120, weak and compressible. The temperature 101·2°. The facial expression was almost like that of cholera. As the end was evidently approaching rapidly, treatment was directed solely to relieve her great agony, this being accomplished by large hypodermic injections of morphia, along with hot poultices and poppy fomentations to the abdomen. Relief was thus obtained. At about 11 P.M. the patient said that all her pains were gone, and spoke quite rationally to the house-surgeon, Mr. Coen, who was looking after the hypodermic morphia. About a quarter of an hour afterwards she suddenly collapsed, and died immediately.

The post-mortem examination was made ten hours and a half after death, in the presence of Dr. Quinlan and Dr. Kendal

Digitized by Google

Franks. The deceased was a fairly nourished woman, and upon opening the abdomen the intestines were found distended with gas, and the contents of the stomach effused into the peritoneal cavity. There was much peritonitis in the upper and left portions of the abdomen. On examining the stomach, a perforating ulcer about the size of a bronze penny was found in the middle of the lesser curvature, and equally divided between the anterior and posterior aspects of the stomach. The ulcer was divided into two portions by a cord of gastric substance which stretched across it. Beside the ulcer there was a thickening of the gastric parietes about the extent of a crown-piece, and evidently the result of old gastric disease. On the inside of the lower curvature were three bright-red patches of congestion of the mucous capillaries, each about the size of a sixpence. The stomach contained a small quantity of dark grumous fluid, which was tested in the medical laboratory for mineral irritants, but with negative results.

The case was evidently one of chronic ulceration of the stomach, which had greatly thinned the parietes of the organ when the perforation occurred, probably as the result of the straining incidental upon the strong purgative dose already described. The remarkable feature, however, is the fact that, with extensive acute peritonitis accompanied by very severe agony, there was a complete absence of pain when the hand was pressed upon the abdominal surface.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Genito-urinary Disease in Animals.—Pathology of Colles' Fracture.—Extra-uterine Fœtation.—Rupture of Bladder. Cerebral Tumour.—Multiple Perforative Necrosis of Skull of Tubercular Origin.—Horny Growth on the Hand.

AN ordinary meeting of this Society was held on Tuesday last, Sir James Paget, Bart., F.R.S., President, in the chair.

Mr. BLAND SUTTON related some cases illustrating Diseases of the Genito-urinary Organs in Animals. The first specimen consisted of the kidney of a sloth which had lived in the Zoological Gardens twelve years. Occupying the pelvis of the kidney were two calculi; one was small and weighed 2 grains, the other 12·83 grains. Chemically they were found to be composed principally of oxalate of lime. Although renal calculi are not uncommon in domesticated animals, they seem to be excessively rare in wild ones. A remarkable case of distension of the vaginal, cervical, and uterine cavity of a hog deer was described, and a uterus from an agouti was shown, in which some pieces of placenta and fœtal membranes had been retained. Inflammation and suppuration of the mucous membrane (suppurative endometritis) resulted; the pus made its way along the left cornu and Fallopian tube, and an abscess formed in the ovary, which ruptured into the peritoneal cavity and brought about the agouti's death by acute peritonitis. Details of a case of inflammation of the oviduct of a fowl were related. The bird during life laid eggs of very small size, and without yelk. When the bird was killed the infundibulum of the oviduct was found adherent to the ovary, so that the ova could not fall into the duct; the intestines were matted together by inflammation. A pelvis of a baboon was shown with the viscera *in situ*. The uterus exhibited a severe retroflexion. During life the animal presented well-marked symptoms, which were attributed to the condition of the uterus. Some remarks were made regarding the existence of ripe ova and follicles in the ovaries of the human fœtus, and in those of the embryos of various and diverse species of mammals.—Sir JAMES PAGET thought it would be difficult to over-estimate the value of Mr. Sutton's work, for it illustrated the influence of conditions of human life on newly imported animals and the influence of close confinement on animals not submitted to the ordinary accidents of their life. It seemed that they became subject to varieties of the same diseases that affected human beings. He asked whether the diseases in animals just after importation differed much from those found in animals long resident in the Gardens. The diseases of animals in their native state might be thus differentiated.—Mr. BLAND SUTTON said that it was the first twelve months that settled the question whether the animal would be very diseased, or whether it would go on an indefinite time and become acclimatised.

Mr. D'ARCY POWER read a paper on the Pathology of Colles's Fracture, and drew attention to the large proportion of fractures of the lower end of the radius in which the lower fragment was comminuted into the joint. He believed that, from a pathological standpoint, this variety of fracture is more common than the simple form ordinarily described: and he held that, without dissection of the injured part, it was often impossible to distinguish the simple from the comminuted fractures, since the deformity might be identical. He related the case of a man, aged thirty-nine, who fractured his wrist, and sustained such other injuries that he died. During life, and even after death, when a more careful examination could be made, the wrist presented the symptoms of an ordinary Colles' fracture, and it was only upon dissection that the true nature of the injury was apparent. The lower end of the radius was seen to have undergone a very complete crushing, the wrist-joint being implicated in more than one place. Since the occurrence of this fracture, Mr. Power had examined several other cases which appeared to be of the ordinary type, but which, upon dissection, proved to be in reality comminuted. He exhibited the six specimens before the Society. He had also collected details of cases in which, after almost identical injuries, a fairly useful joint had resulted. He concluded his paper by observing that, although the pathological interest attaching to these cases was great, he believed that the clinical importance was but small, since it was difficult to distinguish between the two classes in the first place, and when that was done the final result appeared to be almost equally good. In examining the specimens preserved in the various pathological museums in London, Mr. Power had only found twenty-five cases of simple fracture, as against thirty-two, in which, the lower fragment of the radius being comminuted, the fracture had extended into the joint, thus bearing out the observation of Mr. Clement Lucas that pathological specimens showed a very large proportion of comminuted fractures.—Sir JAMES PAGET asked if the history of the manner in which the patients fell was known.—Mr. GILBERT BARLING had seen cases of simple, impacted, and comminuted fracture into the joint, but this anatomical knowledge would not be of therapeutical value.—In reply, Mr. POWER agreed with the last speaker, and said that indirect violence was the cause of all the fractures, but the exact method of its application was very difficult to discover.

Dr. GRIFFITH showed a specimen of early Pregnancy in the fimbriated extremity of a Fallopian tube, with large extra-uterine hæmatocele; also specimens of Decidual Casts from the Uterus, discharged in cases of tubal pregnancy. The patient, who had been under the care of Dr. Matthews Duncan, was a nullipara, aged thirty-two. The catamenia had been absent four months; she suffered from morning sickness, severe right iliac pain, and metrostasis. The usual signs of early pregnancy were present, and a small, rounded, not tender, swelling was found on the right side of Douglas's pouch. Eight days before death she passed a decidual cast; and three days later, after a severe attack of pain, she became collapsed, and remained so until her death. A large hæmatocele had formed, filling the pelvis and extending into the hypogastrium, in which the blood was coagulated and shut off from the general peritoneal cavity by recent adhesions between the omentum and small intestines, illustrating the usual anatomy of hæmatoceles, if the patient survive the effusion of blood for a few days. Dr. Griffith stated that, in spite of what had recently been written to the contrary, the large majority of effusions of blood of considerable size in this region are intra-peritoneal and true hæmatoceles, whilst the large subperitoneal effusions or hæmatomata, described by Mr. Lawson Tait and others, were, for the most part, a new disease produced in abdominal operations involving the broad ligaments, and were due to a vessel being left insecure in the broad ligament, leading to a sudden or gradual distension of it with blood. The decidual casts are probably diagnostic of extra-uterine fœtation, and are easily distinguished by their size and thickness from the menstrual casts of so-called membranous dysmenorrhœa. Both tubes present similar appearances of past disease, the outer third of each being dilated, and the mucous membrane partially destroyed; the inner two-thirds of each tube appeared healthy, but on microscopical examination the mucous membrane was found to be nearly destroyed, only a thin layer of the deeper part remaining, and the columnar

Digitized by Google

epithelium had disappeared from all parts. These conditions were probably the result of past destructive inflammation, and were sufficient to account for the arrest of the ovum in the entrance of the tube. The muscular wall of the tubes was thickened, as were the walls of the vessels.

Mr. BRUCE CLARKE showed a specimen and drawing of Bladder Ruptured at its Apex. All the coats were ruptured except the peritoneal coat, and the blood was extravasated in the subperitoneal tissue. The man, aged seventy-five, had a stricture of the urethra, and had been run over. The bladder was columnar in shape.—Sir JAMES PAGET said the muscular coat was much thinned.—Mr. W. RIVINGTON asked whether there was any sign of tunicary herniæ, which were most numerous about the ureters and urachus, and might be the cause of the rupture.—In reply, Mr. BRUCE CLARKE said he took it to be some sudden rupture without extravasation of urine, of which there was not as much as a teaspoonful between the ruptured coats.—Mr. E. HURRY FENWICK quoted Mr. Rivington's statistics to show the position of the rupture in one hundred cases. Eighty-eight times the rupture was situated on the posterior surface. A case of litholapaxy was mentioned in which there was vertical rupture of the bladder between the interuretal bar. The entire thickness of the muscular wall of the bladder was torn, but not the peritoneum; pelvic cellulitis resulted in death. The rupture had evidently been made by the evacuator having been used too violently in a small bladder. He referred to the case because of its illustrating an entirely new class of violence acting on the posterior wall—a uniform fluid pressure acting from within and tearing the viscus posteriorly and vertically. He contended that the occurrence of fatty degeneration and inflammatory softening were insufficiently recognised as causative elements in the production of rupture. These pathological changes affected certain parts more than others, and the posterior wall was a common seat of both changes. This was interesting in relation to the frequency of posterior rupture.—Mr. R. J. GODLEE inquired whether in the operation of litholapaxy it was possible that the lithotrite or catheter had caused the rupture.

Mr. GILBERT BARLING showed a Tubercular Tumour of the Brain, which occurred in the practice of the late Dr. W. Russell of Birmingham. It came from a boy aged twelve years, who died in 1859 from ascites and anasarca of renal origin. Epileptiform fits on the right side without loss of consciousness, subsequent partial paralysis of the right limbs and right side of the face, and jerky movements in the paralysed limbs were noticed. The tumour was situate at the junction of the anterior and middle lobes of the brain in the upper part of the left "motor" area. The surrounding tissue was not softened. A few bacilli were found in the caseous part of the tubercular mass. The tumour was very circumscribed, and gave rise to symptoms only five weeks before the patient's death.—Dr. OWLES asked whether there was any scrofulous disease of the kidney.—Dr. NORMAN MOORE thought there might have been tubercles in the pericardium. He had found tubercles in the adherent pericardium in children who had tubercle in other parts of the body.—Mr. BARLING, in reply, said there was no record of scrofulous or tuberculous disease in the kidney.

Mr. BILTON POLLARD showed the Vault of a Skull, in which there were four perforations, which had resulted from tubercular disease of the bone. The specimen had been taken from a female child aged ten months, when she first came under Mr. Pollard's care at the North-Eastern Hospital for Children. At that time there were four chronic abscesses on the skull, for which no cause could be assigned. They were opened, and found to be situated immediately over the bone. They were all scraped out. The smallest abscess healed in a few weeks, without causing perforation of the bone, but the others remained fistulous, and a fifth abscess formed over the occipital protuberance; this was treated like the others, and ran a similar course. Four months later sequestra, involving the whole thickness of the skull, were removed. Three of the abscesses then healed soundly, but that over the occipital protuberance never quite healed. After the removal of the sequestra the child rapidly wasted, and two months afterwards she died. There were a few patches of caseous tubercle in the lungs, and the bronchial glands were caseous; the mesenteric glands were enlarged. The skull presented four perforations, the borders of three of which were smooth and healthy, but there were signs of disease still present along the upper border of the perforation in the occipital bone. Mr. Pollard had examined some of the granulation tissue, and one of the pieces of bone which had been removed, but though they showed the microscopical structure of tubercle, he had failed to detect any tubercle bacilli in them. There were no signs of syphilis of the skull. Volkmann (*Centralblatt f. Chirurgie*, 1880, p. 8) had described similar cases, which he considered to be of tubercular origin. — Mr. G. BARLING had seen a similar specimen in a child less than twelve months of age. This child had a cyst in the back. Excision of the cyst was practised and two small sequestra of the laminæ of the vertebræ removed. Meningitis followed, and death supervened. At the necropsy circular sequestra of the bones of the skull were discovered. These were not due to syphilis, but a protracted search would probably be required before tubercular bacilli could be discovered, if at all.—Mr. W. G. SPENCER referred to a case of tuberculosis of the skin in a woman aged forty, in whom necrosis of the skull was present. Tubercle bacilli were found in the cutaneous lesion, which had some resemblance to syphilitic disease. — Mr. A. E. BARKER showed a specimen of tubercular disease on the inner aspect of the skull. It was removed from a child who had suffered from very extensive caries of the spine; there was no evidence of intra-cranial disease during life. After death a whitish patch over the greater wing of the sphenoid was found between the dura mater and bone; the disease had penetrated the bone and produced a rarefying osteitis of tubercular nature.—Dr. T. D. ACLAND testified from considerable experience to the difficulty or impossibility of finding tubercle bacilli in chronic scrofulous lesions.—Dr. DAWSON WILLIAMS said that inoculations in guinea-pigs with material from tubercular joints gave rise to generalised tubercle, the lesions of which showed typical bacilli, though they were not found in the inoculated material.—Mr. A. A. BOWLBY testified to the rarity of the affection of the cranial vault by tuberculous processes. He accepted Mr. Pollard's views of the specimen. He agreed that the presence of bacilli was not necessary to the diagnosis of tubercle. The bacilli might be there in very small numbers. The same paucity of numbers existed in lupus.—Mr. BILTON POLLARD, in reply, said that Volkmann had collected eleven cases, in some of which caries rather necrosis was the chief feature. In his own specimens the necrosed bone appeared to have been previously infiltrated by tubercular material.

Dr. EDMUNDS showed a specimen of Horny Papilloma of Hand from a woman aged seventy-five. It occupied a great part of the surface of the back of the hand. There was about an inch in thickness of horn. The papillæ of the skin were hypertrophied. The hand had been burnt seventy years previously.—Mr. B. SUTTON asked whether it was to be regarded as a horny epithelioma.—Sir JAMES PAGET thought the ulcerated surface resembled that of an epithelioma.—Mr. EDMUNDS said that the growth did not extend in depth below the cutis.

The following card specimens were shown:—Mr. E. H. Fenwick: Carcinoma of Prostate. Mr. Targett: Extra-peritoneal Rupture of Bladder.

CLINICAL SOCIETY OF LONDON.

President's Address.—Nephro-lithotomy.—Renal Surgery.

AN ordinary meeting of this Society was held on the 28th ult., Dr. W. H. Broadbent, F.R.C.P., President, in the chair. Owing to the lateness of the hour, the discussion on the surgical papers was postponed till the next meeting.

Dr. BROADBENT gave his inaugural address as President of the Society, and expressed his high sense of the honour and responsibility attaching to the post. If he had had an ambition outside and beyond the performance of his duty, it was certainly that of figuring as President on the honoured *rôles* of one or other of the Societies. Alluding to the progress which had been made in the study of morbid anatomy, pathology, and therapeutics, he congratulated the profession on the fact that every day tended to render practice more scientific, and that pathology and therapeutics now went hand in hand. Diagnosis was one of the most important elements of success in the career of medical men. A well-known barrister of his acquaintance, in his post-prandial chat, was wont to say that, to paraphrase an aphorism of Demosthenes, the first element of success at the Bar was good animal spirits; the second, good animal spirits; and the

Digitized by Google

third, good animal spirits. In the same way, he would be disposed to say that the great element of success in medicine was diagnosis. By diagnosis he meant careful and exact localisation of lesions. It was not diagnosis to say that a patient had paraplegia unless the nature and site of the lesion was ascertained. As to the mere fact of some cases proving exceptional, he recalled the saying of Sir James Paget, that "an exception to one rule was in reality the first indication of another and possibly unknown rule," and might therefore be the means of enabling the careful and attentive observer to carry out useful observation on a new line. He observed that in the Transactions of the Society the surgeons appeared to better advantage than the physicians—a state of things probably attributable to the fact that physicians' cases did not lend themselves to exhibition as did the surgeons' cases. The physician could, and often did, point to the arrest of phthisis in individuals and communities; the progress of Bright's disease might be staved off indefinitely if the patient only carried out the treatment laid down for him; but such cases scarcely admitted of being shown, and in any case did not appeal to the attention in the same way as the more palpable results of the surgeon's intervention. He deprecated anything in the nature of scepticism in regard to the use of drugs, and declared that when physicians used drugs they did so in good faith. Alluding to the class of drugs known as antipyretics, he said that, while very useful in a certain category of cases, the mere knowledge that they lowered the temperature was not a sufficient justification for their use. It was necessary for the physician to know *how* the temperature was lowered before he ventured to lower it. The mere existence of fever was not a sufficient reason, and there were many cases in which it was doubtful whether a reduction in temperature was desirable or beneficial to the patient. The physician was not in a position to say that a high temperature was *per se* a symptom to be combated, since it might be a necessary item in the evolution of the morbid phenomena. Referring to the employment of the salicylates in the treatment of acute rheumatism, he acknowledged that many of the inconveniences and sequelæ of that disease were abridged or prevented by its use. At the same time he enjoined a certain caution, especially in prolonged courses of the drug. He said that, since its use had become general, he had certainly seen deaths from rheumatic fever of a kind he had not met with before. In conclusion, he thanked the Society for the honour they had conferred upon him.

Mr. HENRY MORRIS read a case of Calculous Disease of both Kidneys, with remarks on the Surgical Treatment of Calculous Kidney generally. A woman, aged forty, was sent to Mr. Morris at the Middlesex Hospital on June 15th, 1886, by Mr. Nunn, for the purpose of undergoing an operation for calculous disease of the right kidney, associated with a purulent fistula of long standing in the right loin. The patient was very ill at the time, had passed several small calculi, and complained of severe pain in the right loin and frequency of micturition. Within a few days some pain had also been felt in the left loin. There was a history of albuminuria of long standing. On June 18th the right kidney was explored through an incision in the loin. The tissues round the kidney were condensed, indurated, and tenaciously adherent to the renal capsule; the kidney was small and hard. On cutting into the kidney several small calculi and some fragments of pyogenic membrane, but no pus, were removed. The operation was followed by no relief, and more intense pain was experienced on the left side. Partial and then complete suppression of urine followed, and the patient died comatose on June 23rd. At the post-mortem examination the left kidney was found very large and white, and with a great increase of cortical substance. It contained two cysts filled with pus, in one of which there was about two hundred small calculi. Numerous other calculi were scattered through the kidney. The right kidney was small, hard, and contracted, and one or two minute calculi were found scattered in its substance. There was no calculus in either ureter, and no other cause of ureteral obstruction present. It is argued from such a case as this that the surgeon may be easily misled by clinical symptoms, and also by abdominal exploration, to operate upon the wrong kidney —viz., one which, though the seat of a calculus, is not the organ which is exciting the present symptoms, these symptoms being caused by the second kidney having become calculous after it had undergone hypertrophy, owing to previous long-standing calculous disease in the first. Such cases are not favourable for operation, and differ vastly from the more numerous cases which are cured or relieved respectively by nephro-lithotomy and nephrectomy.

Mr. HENRY MORRIS read a case of Successful Nephro-lithotomy. A man aged forty-two, who for ten years had been suffering from symptoms pointing to renal calculus, was sent to Mr. Morris by Dr. George Johnson on May 4th, 1886. He was admitted into the Middlesex Hospital on May 12th, and operated upon on May 15th. A rough rounded calculus, weighing 23½ gr., was removed through an incision in the loin from the right kidney. There was no pus in the kidney. After the operation no urine whatever escaped by the wound, but blood in decreasing quantity was passed in the urine for some days. The wound healed by direct union. The patient sat up on the sixteenth day, and was discharged perfectly well at the end of the third week after the operation. For a long time prior to coming under notice he had taken very large quantities of brandy and laudanum to relieve pain; these were entirely discontinued from the time of the operation, as all pain ceased from that time. He has been several times seen since he left the hospital, and is in good health and passing natural urine.

Mr. HOWARD MARSH read a case in which very severe symptoms were due to two small Stones in an Atrophied and Movable Kidney; failure to detect the organ by an anterior lumbar incision; discovery by laparotomy; successful removal of the kidney. The patient, aged twenty-five, unmarried, was admitted into St. Bartholomew's Hospital on June 29th, 1886, with well-marked symptoms of stone in the left kidney, constant pain, severe exacerbations, frequent micturition, and pus and blood in the urine. As no improvement followed rest and medical treatment, it was determined to explore the kidney. For this purpose an incision, suggested by Mr. Willett, and which had several times been found highly advantageous for the removal of large kidneys, situated exactly half way between the spine and the middle line in front, and vertical in direction, was made through the abdominal wall and fascia transversalis. The kidney, however, could nowhere be found though a wide search was made. On a subsequent occasion the abdomen was opened in the middle line, and the hand passed in. The kidney was now easily detected, but found to be movable and atrophied. No stone, however, could be felt. The kidney was then removed by the ordinary lumbar incision. The patient made a bad recovery. On opening the kidney after removal two small stones were found in one of the calyces. The author drew attention to the important fact that, though the symptoms were very urgent, the stones on which they depended were of very small size. He pointed out that, though the incision in the axillary line is ordinarily adopted for the removal of a large kidney, the posterior lumbar incision is preferable for the purpose either of mere exploration or the removal of a stone from the kidney; and he discussed the means that may be adopted for the detection and removal of small renal calculi. He also raised the question how far the symptoms in the present case may have been due to the fact that the kidney was freely movable.

Mr. WILLIAM H. BENNETT read a case of supposed Nephrotomy for Scrofulous Disease. The patient, a married woman, aged thirty-seven, was admitted into St. George's Hospital under the care of Dr. Champneys on Dec. 25th, 1885, on account of abdominal tenderness, painful micturition, and a reniform swelling on the left of the umbilicus which rapidly increased, and by Jan. 8th extended into the left loin. On the 14th there was a sharp rigor, fluctuation became manifest in the mass, and a considerable amount of pus appeared in the urine, which was neutral in reaction and up to this time had only been slightly turbid. Exhausting vomiting set in, and the case was transferred to Mr. Bennett's care, who, on Feb. 3rd, laid open the tumour freely through the left loin, whereupon a large quantity of curdy partly caseating discharge poured out, with a foul urinous odour. On the finger being introduced into the cavity it entered what was apparently a disorganised scrofulous kidney, there being a large sac with irregular imperfect septa formed, so far as could be judged, by the undestroyed calyces running in the usual direction. At the inner aspect was a pouch-like offshoot, which was thought to be the dilated ureter. Great relief followed the operation; the patient was progressing favourably in every respect; the abscess contracting rapidly until Feb. 18th, when lung compli

Digitized by Google

cations set in, of which she died on the 28th. Post-mortem examination: There was a small wound in the left loin leading into a sacculated abscess of small size, at the inner and anterior part of which lay the kidney *absolutely intact*, not having been involved in the operation at all. The organ, on being cut open, was found in a condition of scrofulous disease, but had not broken down to any extent. Difficult as may be the differential diagnosis of renal and peri-renal abscess, Mr. Bennett was unacquainted with any case in which doubt had arisen, after free incision, as to the situation of the disease. In his case, so exactly in every way did the cavity resemble the interior of the kidney at the time of operation, that no surgeon could have doubted that the kidney had been laid open. Had the patient survived, as she might have done but for the occurrence of lung disease, the abscess would certainly have healed, and the case probably have been recorded as a successful instance of nephrotomy for scrofulous disease. As it seemed not impossible that similar sacculated abscesses may have been opened by other surgeons under the impression that the kidney had been incised, Mr. Bennett thought the case not without interest in connexion with the statistics of the result of treatment of scrofulous kidney by incision.

The following living specimens were shown:—Mr. R. J. Godlee: Removal of both Upper Jaws for Epithelioma of Hard Palate. Mr. R. W. Parker: An Unusual Form of Hare-lip. Mr. J. R. Lunn: (1) A boy with Ichthyosis; (2) Peculiar Deformity of Feet in an Ataxic Patient; (3) A man with Raynaud's Disease of the Feet; (4) A case of Myxœdema with want of Development of the Genital Organs.

Mr. HENRY MORRIS exhibited four Renal Calculi and cases illustrative of successful Nephro-lithotomy.

OPHTHALMOLOGICAL SOCIETY.

Treatment of Conical Cornea.—Calcareous Film of Cornea. — Choroidal Hæmorrhage. — Exostoses of Skull, with Atrophy of Optic Nerves.—Unusual Clinical Cases.—Acute Cerebral Disease, with Ocular symptoms.

AN ordinary meeting of this Society was held on the 27th ult., Mr. E. Nettleship, F.R.C.S., Vice-President, in the chair.

Mr. COWELL showed three patients with Conical Cornea treated by transverse incision, which he preferred to vertical incision. Text-books averred that conical cornea was commonest in women; but his experience was different. Two of his patients had asked that the second eye might be operated upon, they were so gratified with the results.—Dr. BRAILEY thought women were more commonly affected. He preferred a vertical section, but had of late simply made a vertical groove in the cornea and then stitched the edges of the groove together.—Mr. HIGGENS said that women were most frequently affected, and hypermetropic eyes were more prone to it than others. After operation a convex glass greatly improved the sight.—Mr. MCHARDY had seen it only in very young men. He preferred trephining to removing an elliptical flap; but the latter was attended with less pain and retention of aqueous fluid. The horizontal was better than the vertical section. — Mr. ANDERSON CRITCHETT observed that anterior synechia was noted in 50 per cent. of the cases operated on, and iridectomy was necessitated. He began with a minute vertical iridectomy, and ten days later another iridectomy outwards, and afterwards an elliptical portion of the cornea was removed.—Mr. LANG thought the incision should be wider than the size of the pupil, and so adhesion of cornea and iris could be avoided. He cut out a short, nearly circular ellipse.—Mr. HARTLEY concurred with Mr. Lang, and was struck with the apparent length of the scar in the cases exhibited.—Mr. COWELL claimed no originality for the vertical method, but thought it had fewer inconveniences than others. He would not employ a suture, for it set up irritation. The two surfaces of the cut cornea adapted themselves better if the incision were long.

Mr. MARCUS GUNN showed a living specimen of Transverse Calcareous Film of both Corneæ. The left eye had defective vision, and originally squinted. The chief features of interest were the causation and treatment. The man was a blacksmith, and had been exposed to blasts of cold air as well as to great heat. The vision in the right eye was still fairly good. Mr. Gunn proposed to scrape away the calcareous matter. There had been no keratitis or iritis. There was no family history of gout or rheumatism. The film reached to the extreme inner edge of the cornea, but did not slope. In these two features it differed from those shown by Mr. Nettleship.

Mr. W. H. JESSOP read the sequel to the case of Large Semicircular Hæmorrhage. The eye has recovered with perfect vision, and without a scotoma. He concluded that the extravasation had probably occurred into the nerve-fibre layer.—Mr. QUARRY SILCOCK said that the case of large hæmorrhage shown by him at the last meeting had resulted in a white patch of choroidal atrophy, which therefore justified his calling the case choroidal rather than retinal hæmorrhage.

Mr. W. LANG showed a case of Central Detachment of Retina of obscure origin in a widow aged sixty-three, a semptress.

Mr. E. NETTLESHIP showed a living specimen of Congenital Multiple Symmetrical Exostoses of Skull, with Post-papillitic Partial Atrophy of Optic Nerves. The boy, aged twelve, was much undergrown, but fairly healthy and intelligent. There were very large and perfectly symmetrical smooth exostoses in the temporal and mastoid regions and on the outer wall of each orbit, laterally, and at or near the situation of the anterior and posterior fontanelles in the middle line. The coronal suture could be felt as a groove on the temporal and anterior median exostoses. At the sides of the root of the nose there is a gap between the nasal process of the frontal and of the superior maxillary bones, but the central ridge formed by the nasal bones is normal. Numerous large veins emerge from or pass into the gap on each side of the root of the nose; and others are seen in the temporal regions. The eyes are too wide apart, the orbits being separated apparently by expansion of the median bones. When the mouth was opened the lower jaw was dislocated forwards, but without causing inconvenience; probably the shape of the glenoid cavity is much altered. The roof of the palate is very high and narrow anteriorly; with this exception, the facial bones seem to be quite natural. The smell and hearing were good. There was no other deformity. Both the optic discs were pale, with clear evidence of former inflammation. The left showed more change than the right. Vision is defective: right, 14 J.; left, 16 J.; less than $\frac{5}{60}$ with either. The refraction was hypermetropic, 3·5 D. He could read better with the aid of + 3 D. The head was of its present shape at birth, but the bosses have become less conspicuous as he has grown. The sight has been in its present state all his life, so far as could be ascertained. There were no other cases in the family.

Mr. P. H. MULES read a paper on some Unusual Clinical Cases. 1. Pseudo-sarcoma of iris. A case of solitary gummous tumour of the iris simulating sarcoma, in a child aged thirteen months. There was no iritis or other appearance of syphilis. The growth was dispersed by mercurial inunction in seven weeks, leaving the eye normal. 2. A deep and extensive crescentic ulcer of the cornea (Wecker's malignant ulcer), with splitting of the corneal layers to the apex, permitting passage of probe (a very rare condition), occurring in a man aged fifty-four, arrested by scraping and iodoform. The case was a crucial one, and Dr. Mules pointed to it as proof of the efficacy of scraping and antiseptics. 3. A second case of corneal ulcer in a man aged fifty-six suffering from Graves's disease. The ulcer was painful, and was complicated by posterior synechia. All minor treatment failed, and the cornea being in eminent danger of destruction, the lids were united over four-fifths of their length. The pain was at once relieved, and the ulcer healed rapidly without further treatment. The interest of this case was accentuated by the record of corneal losses from Graves's disease recently published. 4. A case of double auto-extraction, the result of accident, in a man aged sixty-seven, with retention of useful vision in both eyes. 5. Extraordinary foreign body retained in globe: a dart from puff and dart encapsuled for eleven days. 6. Scleral hernia from direct violence on the front of the eye; media transparent. Papilla with an irregular margin of sclera, forced out and destroyed; central artery reduced to white lines; vein retaining its normal patency. It was believed that this was the only case in which this accident had been observed.—Mr. CRITCHETT related the case of a lady who had been shot in the eye with a dart nine months before. During the enucleation of the eye for sympathetic ophthalmitis the dart was found to have penetrated the optic nerve, and lay outside the eye in the orbit.—Mr. G. A. BERRY had examined the

Digitized by Google

case of exophthalmic goitre, and the result seemed to be most satisfactory. Was it requisite to pare the edge before bringing the lids together? He had recently seen a similar case in which good results were obtained without paring the edges. —Mr. HIGGENS referred to the crescentic ulcers; they were more amenable to treatment by eserine and bandaging than by any other method of treatment.—Dr. BRAILEY thought that cases where there was no infiltration of the base of the ulcer did best with eserine; where there was infiltration, the galvano-cautery was very useful.—Mr. MARCUS GUNN said that in one case of fairly clear, greyish, serpiginous ulceration, extending half round the entire cornea, he had employed the galvano-cautery with great success.—Mr. SIMEON SNELL alluded to the value of quinine in two-grain doses three or four times a day.

Mr. G. A. BERRY read three cases of Acute Cerebral Disease with Ocular Symptoms. His first case was one of acute ophthalmoplegia externa in a little girl, aged two years and a half. There was a history of gastro-enteric catarrh five months before admission. The present illness began three weeks ago with cough and headache. Ten days before something wrong was noticed with the sight. There was almost complete ptosis of both eyes, with absolute divergence of eyeballs—in fact, a condition of almost complete ophthalmoplegia externa. The child was mentally very apathetic; once she had a severe screaming fit; the knee-jerks were absent. After treatment by iodide of potassium for two weeks, distinct improvement in the general condition began, and the ophthalmoplegia was less marked. There was a scrofulous condition of one finger. The pathology of ophthalmoplegia was reviewed. Perhaps the condition was dependent on tubercular disease about the ocular nuclei. The second case was one of megrim associated with spasm of convergence, in a girl aged eighteen. The possibility of hysteria being the cause was considered. On one occasion the patient had an attack of apparently insurmountable conjugate deviation of the eyes to the left. Extraordinary abnormalities of temperature of the body were observed. The corpora quadrigemina or the cortex might be the seat of the nervous lesion. The third case was one of recurrent attacks of bitemporal hemianopia. The patient was a man aged fifty-three, who had suffered from headache and drowsiness. Both temporal halves of the fields of vision were extremely defective up to about 5° from the points of fixation. On six occasions, at intervals of about one week, and for three or four days, vision became affected and the temporal fields of vision dimmed or obliterated, whilst at the same time the heart's action was markedly slower than during the periods of intermission of the ocular symptoms. Pressure on the chiasma in an antero-posterior direction might be the cause of the hemianopia.—Dr. GOWERS said the cases were difficult. He agreed with Dr. Berry that it was highly probable that different cases of external ophthalmoplegia had different pathological lesions, especially judging from what was known of ophthalmoplegia interna. The loss of light-reflex, usually attributed to degeneration, might pass away even in tabes. Where recovery took place, the lesion could not be a destructive one, though there might be some nutritional change. With regard to the first case, he doubted whether it could be due to distension of the aqueduct or to a simple tubercular lesion. Distension of the aqueduct was frequently met with without paralysis of ocular muscles. Sudden lesions were generally vascular. Thrombosis was common in children; in this case it was probable that a thrombus had occurred in the artery leading to the ocular centre. In the second case, he agreed that the case was not one of hysteria. Divergent strabismus was conclusive against hysteria. As to the third case, no doubt internal hydrocephalus was an occasional cause of pressure on the chiasma, and blindness. He referred to a case where first the decussating and afterwards the non-decussating fibres were affected by the distension of the third ventricle.—Mr. WARREN TAY referred to a case of Mr. Hutchinson's, which recovered.—Dr. SEYMOUR SHARKEY did not accept the tubercular theory of the first case. Many acute cases resembled tubercular disease and got well, but there was not any reliable evidence of recovery after tubercular disease of the brain. He had discovered diffuse inflammation of the basal ganglia when the cerebral symptoms had begun suddenly. He would regard the present case as one of this kind rather than as of thrombotic origin.—Mr. BERRY, in reply, considered that some vascular lesion was most probable in the first case. He had observed one case of external ophthalmoplegia, evidently of inflammatory origin. Spasm of convergence, so far as he knew, was rare; paralysis more common.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AT the ordinary meeting held on Jan. 14th, Mr. Wheelhouse in the chair, the following pathological specimens were shown:—Mr. Lawford Knaggs: Carcinomatous Ulcer of Pylorus. Mr. C. J. Wright: Pedunculated Fibroma of Labium—a large mushroom-shaped tumour ulcerated on the surface. Mr. Mayo Robson: Diseased Uterine Appendages—viz., tube occluded by caseous matter; distended tube with parovarian and small ovarian cyst.

A drawing of Lichen Circumscriptus was shown by Dr. Barrs of a case in which the eruption was produced by wearing flannel.

Mr. McGill exhibited a specimen of a large Cyst near the larynx, removed post mortem.

The following communications were made:—

On the persistence of Palsy in limited groups of Muscles. Dr. CLIFFORD ALLBUTT pointed out the frequency with which this occurred both in cerebral and spinal paralyses, and he held that the theory that it depended on the particular group of cells affected by the lesion was untenable, at all events in cerebral cases. Considering the muscular actions to be carried on by groups of mechanisms, he thought the will acted with diminished power and therefore imperfect control, resulting in the overaction of stronger muscles and consequent spasm through want of their proper antagonisers. This local disorder was to be treated by local means, and he recommended the use of elastic bands to assist in counteracting the spasm of stronger muscles, and spoke highly of the use of tenotomy, which should be done early, before any dislocation &c. could take place. —Mr. WHEELHOUSE said that he and his surgical colleagues had been led to make a very extensive use of tenotomy in the treatment of infantile palsies through the representations of a very skilful surgical mechanician, and had been much surprised at the results obtained.—Dr. MAJOR thought that in polio-myelitis anterior there could be no doubt, from the wasting and altered electric relations of the muscles, that the lesion did pick out certain groups of cells and leave others.—Dr. EDDISON agreed with previous speakers in the benefit to be obtained from surgical treatment.—Dr. CHADWICK thought that stretching the unopposed muscles by means of a splint was more reasonable than cutting their tendons.—Dr. CHURTON thought that in the gradual evolution of the nervous system the later formed parts might be more delicate than the older, and therefore lesions produced different effects; but tenotomy relieved the muscle by removing the irritation of its opponents.—Dr. GRIFFITH thought the same theory could not account for central and peripheral palsies. In lead-palsy there was very little spasm, and he thought deformity arose from the long continuance of the parts in a position like that seen in the cadaver.—Dr. ALLAN had seen excellent results from the use of elastic bands in the practice of Mr. Chauncy Puzey of Liverpool.

Pernicious Anæmia.—Mr. BATES described a fatal case in a patient aged forty-nine. The principal symptoms were shortness of breath, attacks of vomiting, and diarrhœa; there was also an attack of jaundice. At the necropsy the liver was slightly fatty, and the stomach walls were very thin, but had not yet been microscopically examined. Death took place after twenty-four hours' unconsciousness. Another case of the same kind was described, in which also there had been jaundice before death. The stomach was very thin.—Dr. BLACK recommended the use of alteratives in the treatment of anæmia.—Dr. ALLBUTT referred to the definite appearance of pernicious anæmia, as accompanied by extravasations into the retina, and in the curable cases remedied by arsenic rather than iron.—Mr. JESSOP spoke of three patients he had seen, all of whom lived in houses much exposed to sewer air.—Dr. EDDISON doubted the advantage of the term "pernicious." He thought many cases so called were due to ague or syphilis. In all cases he had seen the blood-cells were distorted.

Primary Nerve Suture.—Mr. ROWE described a case where the ulnar nerve and artery were both divided. After securing the artery he joined the cut end of the nerve (the proximal

Digitized by Google

being much retracted) with a carbolised catgut suture passed through the nerve. Two days after the operation the numbness was less. In five days and a half the sensation was the same, but there was some slight movement in the muscle. In thirty days sensation was slightly impaired, and motion was definite, but not perfect. Shortly afterwards the man pursued his occupation. Mr. Rowe referred to cases by Favel, Nélaton, and others; in some sensation partly returned at the end of the second day, recovery taking place at the end of a week. In a case of primary nerve suture reported by Laugier, recovery began on the day of operation. In Page's cases it occurred in nine days; in Pye's cases, in eight days; but there were some errors of localisation in the former. Mr. Rowe compared the rapid restitution of function in primary suture with the later development noticed in cases of secondary suture, referring specially to a case where the sciatic nerve was sutured by Mr. Wheelhouse, perfect function being only restored after several months.—Mr. WHEELHOUSE said that nerve suture was now established as a satisfactory operation, whether primary or secondary; but in one case by the latter he had known the effect delayed for three months. Referring to a case mentioned by Mr. Hartley where a painful tumour formed over the seat of suture of the median nerve, he said that probably some part of the nerve had failed to unite and had become bulbous, and he recommended a fresh operation to remove this.—Mr. JESSOP thought we should in future, in large wounds, fix more divided parts in apposition by sutures than has been the custom. One of the first cases of nerve suture on record was one where he had sutured the ulnar twelve years after division, first removing a bulbous end. On the seventh day the patient could localise a touch.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

AT the meeting on Dec. 23rd, 1886, the following communications were made:—

Malignant Disease of Pancreas and Liver.—Dr. DYSON related this case. The patient, aged forty-nine, was previously under his care for left pleural effusion, for which he was tapped, and he made a good recovery. His colour was suggestive of Addison's disease, and there was a history of alcoholism. The patient applied at the Sheffield Infirmary for relief because the tumour, which was situated in the epigastrium and which was somewhat movable, interfered with his work. The most noteworthy fact in the case was the complete absence of pain and digestive troubles until within a month of his death. During the last month, pain, vomiting, obstruction of bowel, hæmorrhage, and pyrexia supervened, and the patient died of exhaustion. At the necropsy the pancreas was found almost entirely invaded by scirrhus; the neighbouring glands were affected, and there were numerous secondary deposits in the liver, one especially large one in the left lobe. No other deposits. Left pleura adherent.

Tremor and Incipient Graves' Disease.—Dr. DYSON introduced this patient, an iron-turner, aged thirty-six. The tremors were fine and generally distributed, and probably due to chronic alcoholism. Cardio-vascular symptoms were the first to appear, and slight exophthalmos and Graefe's lid symptom came on quite recently. Pulse 150. He had also a slight internal squint and dilatation of the pupil of the left eye; no glycosuria. Many drugs had been tried for his relief, but none so far was obtained.

Some Clinical Features of Graves' Disease.—Mr. SNELL read this paper, based on cases coming under his observation. Referring to those in which the eye symptoms were the first to appear, he mentioned the case of a young woman, in whom the other cardinal symptoms had recently developed, and the patient was introduced by Dr. Dyson, under whose care she was now; also that of a woman, aged forty-five (introduced), with Graefe's and Stellwag's symptoms in right eye; no marked (if any) exophthalmos; slightly enlarged thyroid, and unobserved by patient; absence of other symptoms; left eye normal. Two monocular cases in females were related, besides the one above, as were also two instances of suppuration of both corneæ; the cases coming under observation first when the cornea was seriously affected in one (aged twenty-three), and destroyed in the other (aged forty). The question of Stellwag's (retraction of eyelids) and Graefe's (loss of coördinated movement of upper eyelid and globe on looking down) signs occurring independently of the usual train of symptoms of Graves' disease was discussed, and the following two cases in particular were related:—A young lady, with Graefe's and Stellwag's symptoms in one eye (right); no other apparent symptoms of exophthalmic goitre; greatly improved under treatment. A miner, aged thirty-six (introduced), the subject of miner's nystagmus. In both eyes Stellwag's and Graefe's signs were present; no exophthalmos, enlarged thyroid, or other symptoms of Graves' disease. The man seemed to possess some control over the lid phenomena. Among other points, the pathology was briefly touched upon, and support given by the cases related to a central disease theory (Sattler, Fitzgerald).

WIGAN MEDICAL SOCIETY.

Attendance of Medical Witnesses at Assize Courts.—A special meeting of the Society was held on Jan. 27th, Dr. Berry, J.P., President, in the chair, for the purpose of considering the present procedure in binding over medical witnesses to attend at assize and sessions courts, and the inadequate fees paid for the great loss of time involved. After some discussion upon the hardships entailed upon medical men by being compelled to attend as witnesses for a number of days at these courts, held in Liverpool, before their particular case is disposed of, and attention having been called to the fact that the scale of fees (namely, one guinea per day) was fixed thirty years ago by the then Lord Chancellor, when that sum was of much more value than at present, and there was not the same facilities for the saving of public time, the following resolutions were unanimously adopted:—1. "That it is most desirable that some alteration be made in the present procedure of detaining medical men as witnesses for a number of days at assize and sessions courts, and that adequate remuneration be allowed them for the loss of their time." 2. "That a subcommittee, comprising the president, vice-president, secretary, Messrs. Barnish and Brady, be appointed to consult counsel, and take the necessary steps towards calling the attention of the Crown to this grievance." 3. "That a report of the proceedings of this meeting be sent to the medical journals for publication."

Reviews and Notices of Books.

The Healing of Arteries after Ligature in Man and Animals. By J. COLLIS WARREN, M.D., Assistant Professor of Surgery, Harvard University; Surgeon to the Massachusetts General Hospital, &c. New York: William Wood and Co. 1886.

THERE is probably no theme in Surgery which has commanded a greater amount of interest and attention than the arrest of arterial hæmorrhage. The importance of the process is its just claim to attention, and this is for us greatly strengthened by the history of its gradual development, and the great names that are inseparably connected with the chief steps in the advance of our knowledge and in the improvement in our practice upon arteries. In spite of all that has been done there are many points yet open to discussion. It is still debated whether a ligature should be flat or round, large or small, permanent or temporary, single or double; and whether it should be applied tightly so as to partially sever the vessel, or more loosely so as only to compress it more or less firmly. For some years past Dr. Collis Warren of Boston has been studying with much care the minute processes occurring in the healing of ligatured arteries, and he has embodied his results in a valuable treatise. Dr. Warren has, of course, availed himself of the aid afforded by direct experiment on animals, and the series of vessels thus obtained, together with several human arteries removed at varying times after ligature, have formed materials from which he has been able to trace the entire process of healing. In removing the artery experimented upon, he has been careful not to dissect it away from the

Digitized by Google

body of lymph or "callus" in which it lay, but to remove the mass entire. By examining sections of specimens thus preserved the entire process can be followed far better than when the vessel is dissected out and examined alone.

In many points Dr. Warren confirms the statements of other observers, but several of his facts are so striking that they are certain to excite fresh inquiry. The relative *rôles* of the internal coagulum of Petit and of the various coats of the arteries have afforded much matter for discussion. Dr. Warren attributes to the internal clot a very subsidiary share in the cicatrisation of the vessel. Like others, he finds that the size of this clot is much affected by efficient antiseptic treatment; he does not believe that it plays any active part in the closure of the vessels, but that it forms a very suitable soil for the development of granulation tissue sprouting into it from the neighbourhood of the ligature. The part played by the tunica intima has been variously estimated. Dr. Warren finds that both in animals and in man the endothelium of an artery takes but a small share in the work of cicatrisation. In some specimens it was seen to be undergoing proliferation, and by this means to affix the internal clot to the vessel wall; this may not be seen at the seat of the ligature, but at the other extremity of the clot. The endothelium also proliferates to form a lining for the vascular spaces in the arterial cicatrix; beyond this it does not take any active share in the closure of the vessel, if Dr. Warren's experiments and statements are to be relied on. The tunica media appears to play a very important part, for it is found that a main and essential part of the cicatrix in an artery is composed of long oval cells with rod-shaped nuclei, which are derived from the middle coat, and are to be regarded as involuntary muscular-fibre cells. These cells shoot into the organising tissue wherever the elastic lamina of the intima is broken through, whether at the seat of ligature or at some distance from it. Outside this muscular layer of the cicatrix is a fibrous layer by which it is continuous with the tunica adventitia and the scar tissue in the sheath of the vessel. The fully developed scar of a ligatured artery is therefore seen to be formed of three distinct layers: an innermost, derived from the intima, and consisting of endothelial cells with and without newly formed elastic lamina; a thick central mass consisting of delicate mucous tissue and capillaries, with muscle-fibre cells; and an outer layer of dense fibrillated tissue. Among the many interesting facts observed in this inquiry is the opening out of the artery a short time after its ligature. At first the inner and middle coats are severed and the outer coat is strangled and the lumen of the vessel is completely obliterated. This is quickly followed by the formation of a callus of exudation material around the vessel; the outer coat is then disintegrated at the seat of ligature; this allows of its opening out and of its retraction, and through the aperture thus formed granulation tissue sprouts into the interior of the vessel from the surrounding callus. This process is very clearly seen in several of the diagrams which illustrate Dr. Warren's book, and which have all the appearances of faithful representations of facts. This growth of granulation tissue invades the internal coagulum, and within it blood spaces are formed which communicate with the lumen of the vessel. The muscular-fibre cells sprout out into the granulation tissue, and may sometimes be specially traced around the anastomosing blood channels. The time required for the formation of a complete cicatrix in a large artery is at least from three to six months. Dr. Warren has investigated the changes occurring in arteries in stumps, and the processes leading to the obliteration of the ductus arteriosus and the hypogastric artery. In these he finds corroboration of the above facts. Altogether this book is the record of a very valuable piece of work, and deserves to be carefully studied.

Hygiene of the Eye in Schools. By HERMANN COHN. Professor of Ophthalmic Science in Breslau. English Translation. Edited by W. P. TURNBULL. London: Simpkin, Marshall, and Co.; and the Midland Educational Company, Limited.

THIS is a much-needed work, and one that should be in the hands, not only of every surgeon, but of all those who have the care of children—schoolmasters and mistresses and tutors of all grades and classes, from the heads of our great public schools and colleges to the humblest National school teachers. The work is founded on an article in Eulenberg's Real-Encyclopedie, but the author has added a short and popular introductory chapter on the Anatomy of the Eye, as well as a few remarks on its physiology and pathology. The chapter is of course correctly and simply written, but a doubt may be expressed whether any ordinary layman could, in the absence of special education and dissection, follow the account of the eye and its defects here given. Something, however, will be done if Prof. Cohn can explode some antiquated notions which are very generally accepted—as, for example, the erroneous idea that a short-sighted eye is a good eye, and improves with age. Prof. Cohn very properly maintains without hesitation that a short-sighted eye is a diseased eye, and still more that progressive short sight is in every case ominous of evil for the future, so that not unfrequently at the age of fifty or sixty, if not much earlier, the power of sight, either from detachment of the retina, or from hæmorrhage, or, lastly, from atrophy and degeneration of the yellow spot, is irrecoverably lost. All ophthalmic surgeons will, we are convinced, agree with Professor Cohn in thinking that one of the main causes, if not the only one, is the continual looking at near objects, especially with insufficient illumination. The influence of this unfavourable condition is of course greatly intensified by insufficient food and other lowering causes. Professor Cohn is well known to have been amongst the first to publish statistics in regard to the development of myopia in schools; and his table of results obtained from the examination of 10,060 children has been often quoted. They show that in every school the number of short-sighted children increases from class to class, and that the average degree of myopia rises constantly from the village schools to the gymnasia. The eleventh chapter is devoted to School Desks, and opens with a graphic account by Fahrner of the position and movements of children under ordinary circumstances in writing, and shows clearly the effect of the form and height of the desk, and the position of the slate or copy-book in producing "round" or "skewed" backs; and careful descriptions are given of the proper form, height, slope, and back-rest of model school desks and school seats, in regard to which many points are noted that we venture to say have never crossed the minds of nine-tenths of the teachers in English schools. Prof. Cohn quotes with approval the remarks which have been drawn up by Prof. Esmarch of Kiel, and distributed to parents whose children were crooked. This report says: "School children become crooked and short-sighted by crooked sitting on bad school forms. They sit crooked when the form is too far off the desk, is too low for the desk, and has no back-rest." The proper form is then described, and it is noted that a readjustment of the seat and the desk should be made every six months to meet the requirements of growing children. Another very important chapter is devoted to the Day-lighting of schoolrooms. How many schoolrooms in the country are dark and dingy, dirty in their interior, with small windows, with bad ventilation, and with the desks all placed in a faulty position in regard to the little light that enters. Von Hoffmann of Wiesbaden has recently made the excellent suggestion that in every class-room Snellen's test-types should be hung up, and lessons ended as soon as the day-light is not strong enough to allow a healthy eye to read type No.

Digitized by Google

at a distance of six inches. The author expresses himself in the strongest terms in regard to the amount of light admitted into a school-room: "There can never be too much light in a school." Javal says, "The school must be flooded with light, so that the darkest place in the class may have light enough on a dark day." Prof. Cohn maintains that for every square foot of floor there should be at least thirty square inches of glass. The light should be admitted from the left of the scholars, and of course there should be no high buildings in close proximity to the school to intercept the light. The distance of the opposite buildings should be twice their height. From natural illumination the transition is easy to artificial illumination of schools. The author prefers gas, then petroleum, then oil; the relative illuminating power of these substances being—gas 100, petroleum 87, oil 63. The work concludes with admirable chapters on handwriting, drawing, print, and paper. We have said enough to show that this is a valuable book, and one that should be widely read. The present arrangements in the schools of England are simply disgraceful. We have only praise to accord to Mr. Turnbull for his very well executed translation.

Minutes of the General Medical Council, of its Executive and Dental Committees, and of its Branch Councils, for the Year 1886. With four Appendices. Vol. 23. London: Spottiswoode and Co.

THIS volume has now been issued, and includes a full report of the transactions of the Council and its committees, together with four valuable appendices. The first contains the Standing Orders of the General Council; the second, Visitation Reports on the Universities of Oxford, Cambridge, Durham, London, Edinburgh, Glasgow, Aberdeen, St. Andrews, Dublin, and the Royal University of Ireland. The third and fourth appendices contain respectively the second and third reports by the Statistical Committee of the General Medical Council regarding medical students registered as beginning the study of the profession in the quinquennium 1871-1875.

THE MOXON MEMORIAL.

A MEETING of the friends of the late Dr. Walter Moxon was held in the Royal College of Physicians on the 1st inst., to consider the question of perpetuating his memory by some suitable memorial. Sir William Jenner took the chair at 5 o'clock, and was supported by the treasurer and registrar (Sir Dyce Duckworth and Sir Henry Pitman). Letters were received from Sir A. Clark, Sir J. Lister, and Dr. Wilson Fox, expressing their regret at being unable to attend.

Sir WILLIAM JENNER opened the proceedings by explaining, in a few remarks, that the object of the meeting was to raise some visible sign which should be a lasting memorial of one now passed away, who was honoured for his scientific and professional work, esteemed for his zeal, and universally respected for his high and unsullied character as a man.

Dr. WILKS moved the first resolution, as follows: "That in the opinion of this meeting it is desirable to express, by public memorial, the widespread appreciation which exists of the high character and remarkable personal qualities of the late Dr. Moxon, and especially of the services he rendered in advancing medical science, and in otherwise promoting the highest interests of the profession." He said that as he grew older he was conscious of the ranks of the profession growing thinner around, and it remained for the few to hand down the names of those who had gone before. It was difficult for him to speak of Dr. Moxon, whom he had known as a pupil; but all who had met him were ready to admit that Moxon was no ordinary man. He was a burning and shining light that dazzled men by his brilliancy, so that his companions often ceased to converse and preferred to listen. He threw a halo round every subject he touched. Succeeding the speaker in the chair of Pathology, he soon mastered every detail in that science. Then passing to the chair of Materia Medica, he at once threw a new interest around a very unattractive subject. He was able to strike sparks out of rhubarb and senna leaves. In practice, he endeared himself both by his manner and acumen, and in treating patients his wit was constantly seen. Only the other day he heard of a story of a hypochondriac clergyman who had consulted Moxon. When the patient returned home his wife wanted to know what the doctor called his complaint. On this point the patient was a little doubtful, so it was determined to send his son down to inquire. When the son arrived Dr. Moxon said he could not remember the particular case, but if the son chose to look in his note-book he might there see for himself Moxon's candid opinion. The son looked, and found "a lanky parson with nothing the matter." The diagnosis was taken home and cured the patient. Moxon took pains in everything he did. At the College of Physicians his influence was soon felt, and he made strong friends. How gratifying it was to the friends and relatives to see the esteemed President at his grave, as a mark of respect to his memory, the speaker well knew. Two things they had to commemorate—Moxon's great genius and high scientific contributions to medicine, and his great personal worth, his pure heart, upright conduct, and general integrity. Many illustrious men died without evoking this feeling.

Sir JAMES PAGET, in seconding the resolution, said that Dr. Wilks had left little for him to say, who knew personally so much less of Dr. Moxon, for he had never seen Dr. Moxon at his work at Guy's Hospital; but this slighter acquaintance made the impression he had formed of him perhaps the more remarkable. He knew him only by repute, by his work, and by occasionally meeting him at societies or in consultation; but it was impossible to know him in that way without being impressed by his mental and moral worth. His mind was of a kind which gave free play to imagination, yet went on progressing towards the truth. To him it seemed at first strange and difficult to understand how this should be so, till he learnt that there was always present a most perfect appreciation of facts. At a consultation the beginning was illuminated, but the end was full of the most practical decisions for the patient's good. In society the charm of his wit was most fascinating. In the profession there never was a question but that what he intended to do was always the best according to what he conceived to be right. It was right that such good work should be recorded, and that a memorial should be raised which generations after would respect.

Dr. PAVY moved the second resolution, to the effect that subscriptions should be invited, and that an influential subcommittee be appointed to decide on the most suitable form of memorial. He spoke of the satisfaction it was to him to pay respect to one he had known as a pupil, colleague, and friend, and expressed a hope that part of the memorial fund should be devoted to perpetuating Dr. Moxon's memory at Guy's Hospital.

Sir DYCE DUCKWORTH seconded the resolution, and said that he had known the late Dr. Moxon for twenty-five years, and had often visited him when at work at Guy's. He had the highest appreciation of his character and work. He thought the memorial might be divided between Guy's and the College of Physicians, and hoped that it would be something worthy both of Dr. Moxon, of Guy's, and of the College.

Dr. BRAXTON HICKS and Mr. SIDNEY TURNER proposed that Mr. R. C. Lucas be treasurer, and Dr. G. N. Pitt and Mr. W. A. Lane secretaries to the fund.

The Treasurer of Guy's Hospital proposed a vote of thanks to the President for presiding, and to the Council for the use of the College, which Mr. DURHAM seconded, and to which Sir WILLIAM JENNER briefly replied.

HUNTERIAN SOCIETY.—The annual meeting of this Society will be held on Wednesday, the 9th inst., at 8 P.M., when the oration will be delivered by Dr. Galabin in the theatre of the London Institution, Finsbury-circus. The following is a list of office-bearers for the ensuing year:—President: Dr. Gervis. Vice-Presidents: Dr. Talbot King, Mr. T. R. Fendick, Mr. G. E. Herman, and Mr. G. J. B. Stevens. Treasurer: Dr. Fotherby. Orator: Mr. Clement Lucas. Secretaries: Dr. Charlewood Turner and Mr. John Poland. Council: Messrs. T. E. Bowkett, F. M. Corner, J. S. E. Cotman, G. B. Hicks, T. Mark Hovell, W. Rivington, R. G. Tatham, C. J. Symonds; and Drs. E. G. Gilbert, P. Horrocks, Pye-Smith, and Stephen Mackenzie.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 5, 1887.

WE understand that the promoters of a Teaching University in London are waiting on the Senate of the University of London for an official answer to their representations on the necessity for, and the functions of, a real University in London. In all past discussions on the threefold subject of the University of London in relation to medical degrees, the formation of a Teaching University in London, and degrees for average London medical students, we have not had the advantage of any definite statement from the authorities of the existing University of the policy which they were inclined to pursue, but have been obliged to be content with such side-lights as the present Vice-Chancellor has thrown thereon in his speeches at the last presentation of degrees and honours and at Manchester in November. From these speeches we have learned that the "pass" degrees are considered by the Senate to constitute "distinct honours," and that every successful candidate has an evidence "that he has passed no ordinary standard." We can now go a step further, for we are practically informed, in an article in the current number of the *Quarterly Review*, that the University relies on its past history. For instance, in medicine it is prominently put forward that "the University has probably influenced the profession profoundly and beneficially by confining its distinctions to the *élite* of medical students, and by setting up a high ideal of professional qualification." The author of the article writes as if he were in full knowledge of the views of the Senate, and he has perceptibly striven to justify its present position in—we will not say a complete *non possumus*, but in admitting only minor internal alterations in the character, management, and functions of the University. He also believes that it is in medicine that the University influence has been most powerfully felt and conspicuously successful, so that we must point out a few considerations on the other side of the question. We shall more particularly refer to the medical aspect of the question in our next issue, and will now confine our remarks more especially to the general question of degrees in all faculties.

The fundamental objection to the University of London is in its title. As the author truly says, "In the sense in which Oxford, Glasgow, or Bonn possesses a University—an organised body of teachers confederated for the purpose of attracting scholars, guiding their studies, and encouraging learning by appropriate rewards—London still remains without a local university worthy of its metropolitan position, its population, and its intellectual repute." The chief reason for the continuance of this reproach in the nineteenth century is the usurpation of the title "University of London" by a huge examining board in the metropolis of the empire. From its existence and from its having the power of conferring degrees of Bachelor and Doctor (*Lond.*), the public has been induced to believe that a body which has something to do with teaching as in other universities, and with definite collegiate attachments, really exists in this metropolis as in other centres of learning. This delusion has been strengthened and confirmed by the requirement of certificates of attendance on systematic lectures and hospital practice from medical graduates, although in the other faculties all such restrictions have long been cast aside. Its success as a medical university, even if this were to be admitted, only the more completely proves its failure in regard to the other faculties. Certificates of collegiate education are either valuable or useless. But the University requires them in one faculty and will have nothing to do with them in the others. So we are not any nearer now to a real University than in 1615, and we have to thank the University authorities for not assisting in bringing us any nearer to the ideal placed before us in the Appendix to STOWE'S "Annales" of that date.

The present University from its commencement has thrown cold water on the amalgamation of London colleges and schools, and in 1858 deliberately affirmed that, except in medical training, a collegiate education was unimportant to it, and availed nothing. Therefore it is not to be wondered at that the institutions which have since replaced "the divinity schools at St. Paul's, at Westminster, and at St. Peter's in Cornhill, the King's College in Chelsea, the Inns of Court and of Chancery, Doctors' Commons, the College of Physicians, St. Katherine's College, the College of Heralds, and St. Paul's School," are now no closer in affiliation and corporate union than were these places of learning in 1615. King's College and University College, the Science and Art schools, the Technical Institute of the City and Guilds of London, the Medical Schools, the Colleges of Physicians and Surgeons, the Incorporated Law Society, and the Inns of Court and the large public schools of London are as isolated, so far as the University of London is concerned, in this the jubilee year of its existence as were the bodies above mentioned, when a University of London only existed in the imagination of a few worthy scholars and teachers. The only reasons for this failure in duty on the part of the London University are that this work was not ambitious enough for its early promoters, and that it was pledged by its Charter to encourage many persons who pursue a "regular and liberal course of education both in the United Kingdom and elsewhere." Its first proof of encouraging a regular and liberal course of education was to admit, under pressure of Lord BROUGHAM (*teste* p. 45), unworthy certificates of studentship, and so, instead of rigorously demanding sufficient proofs of regular courses of study, it gradually drifted into the acceptance of more and more loosely given certificates, until they became no guarantees even of an honest, much less of a regular, curriculum of study. It is impossible to believe that the then Senate, had it been so minded, could not have overcome this difficulty. From such a passive position towards the affiliated colleges an open examination allowed a speedy retreat, but even then the authorities shrank from the logical carrying out of their views, and insisted on certificates from candidates in medicine being still forthcoming. The medical schools were in quite as eager competition for

Digitized by Google

students as the affiliated schools and colleges in the Arts Faculty.

The writer of the article above referred to most clearly indicates that he has no sympathy with any modifications which would change the cosmopolitan character (examining only) of the present institution into a metropolitan institution, having relations exclusively to London students, to London academical organisation, and to London teachers, and whilst gravely suggesting that the title of "university" now only means a "*studium generale*, a *schola*, a gymnasium, a corporate body and buildings dedicated to the pursuit of the higher learning," still uses it throughout in its older sense as perfectly applicable to the Imperial Examining Board in Burlington-gardens. What has this body to do with the *pursuit* of the higher learning? We should say, less than many of our first-grade schools, medical and scientific colleges, and yet the most perfect satisfaction is expressed with things as they are, and the whole article is as optimistic as even an official explanation could be expected to be. We have thought it expedient to comment on this past history in order that our readers may be fully aware that since 1858 the University of London has deliberately placed itself in the anomalous position of being only an "examining board" for the empire, and that as a result of such action it is only right and proper in the interests of local London that a true University should, if possible, be founded.

THE discussion which was raised at the Medical and Chirurgical Society on Tuesday week by Mr. BARWELL dealt with a matter of considerable surgical interest—the best method of dealing with hydatid tumours of the liver. The opinions elicited showed that the line of practice is not settled, and it may be well to consider some of the points involved.

One point to which only scant reference was made in the discussion, but which has important surgical bearings, is the great diversity met with in hydatid tumours of the liver. They may be single or multiple, superficial or deep, barren or fruitful; and if multiple, they may be closely grouped together or distinctly separated. These differences have great practical importance. A single superficial cyst may be readily dealt with by simple means, such as tapping. When a number of cysts are present, they may be so grouped together that when the most superficial are opened the others may be opened from their interior; but, on the other hand, they may be so situated that this is impossible, and a deeply seated inaccessible cyst may thus set up mischief, and cause the death of the patient, as in a case alluded to by Mr. WARRINGTON HAWARD. Fortunately these complicated cases are not common; in the majority of instances the tumours are favourably placed for operative interference. The simplest surgical means is tapping the tumour and removing some or all of its fluid contents. But it was pointed out at the meeting that this operation, simple and apparently safe as it is, is not absolutely free from danger, for sudden death has more than once occurred, which in one case at least was found to be due to the entrance of a small cyst into a hepatic vein, through which it passed to the heart. There is, further, the possibility of the leaking of some of the contents into the peritoneal cavity, and a fact incidentally mentioned by Mr. PEARCE GOULD is of interest from this point of view. He stated that while operating upon a case of very large suppurating hydatid, a quantity of omentum was suddenly forced out of the wound, and it was seen to be thickly studded with aborted hydatid cysts. This patient had been previously tapped on two occasions, and the question naturally arises whether the condition of the omentum was caused by an escape of hydatids from the parent cyst. On the other hand, however, it must be borne in mind that these accidents have occurred in a *very* small minority of cases, that tapping has frequently wrought a cure, and that sometimes it is used for diagnostic as well as for therapeutic purposes. If tapping is employed, how much fluid should be removed? Should the sac be emptied, or should only a small proportion of the fluid be withdrawn? On this point two opposite opinions are held, and clear and definite views are needed. The question turns upon the *modus operandi* of the operation. Is it that it causes the ectocyst to collapse away from the adventitious capsule, or is it that the withdrawal of fluid kills the hydatid and prevents the re-secretion of the fluid? Curiously different results of tapping are obtained. In some cases the cyst that has been emptied collapses altogether, and never refills; in other cases it refills with hydatid fluid indistinguishable from that obtained at first; in others, again, the fluid becomes increasingly albuminous after each tapping; in yet others the cyst suppurates. Surely we need more light on this question. We believe that some physicians think that where the nature of the tumour is obvious, it is better at once to proceed to a more radical mode of dealing with it than to trust to tapping, and they base this opinion upon the fact that the cases which are capable of cure by tapping cannot be recognised with certainty beforehand, but that they are just those in which a free incision and drainage is easiest and safest—so safe, indeed, as not to expose the patient to any appreciable risk. They would state the matter somewhat thus: Tapping is dangerous just in those cases in which incision and drainage are necessary for the cure; incision and drainage are free from danger in those cases in which tapping succeeds; therefore, to incise and drain all cases at once, in place of trying the effects of tapping first, is not to expose the patients to any additional risk, but to preserve them from the special risks occasionally attending tapping. Without asserting that this is the correct line of reasoning and practice, we must admit that there is reason in the view, although the perfectly just conservatism of surgeons will probably dispose them still to resort to tapping in apparently suitable cases.

The particular point, however, which Mr. BARWELL dealt with in his paper was the best mode of executing the operation of incision and drainage in superficial accessible cysts. He advocates an application to this case of a well-known surgical manœuvre—operation in two stages—which has had brilliant results in gastrostomy, and has been applied to the operation of enterostomy also. The object aimed at is a laudable one—the exclusion of the contents of the cyst from the peritoneal cavity; but the argument was defective in two essential points. Mr. BARWELL did not show that this escape of contents has been a serious sequela of the operation as more usually per-

Digitized by Google

formed, nor did he show that other means which have been adopted have failed to prevent it. We by no means assert the impossibility of supplying these gaps, but their existence is very evident as the case at present stands. Other means have been employed to attain the adhesion of the cyst to the abdominal wall before incising it, such as the introduction of acupressure pins, the use of caustics, and stuffing the wound made through the abdominal parietes with lint or gauze. Of all methods, we should certainly give the preference to Mr. BARWELL'S suture; it is less painful and more precise than any other; but it is doubtful whether the disadvantage of dividing the operation into two stages is not too heavy a price to pay for the supposed advantages. After the cyst has been freely opened, we have little doubt that the wisest plan is to allow the contents to escape completely, except the mother ectocyst; and not only so, but, as far as possible, the wall of the cyst should be explored for any bulging swellings formed by neighbouring cysts: all such swellings should be tapped and drained through the first. The vessels in the adventitious cyst wall are large and varicose, and the separation of the ectocyst may be followed by serious hæmorrhage. The question of irrigation is one of less moment; where the cyst has suppurated it is probably wiser to at once remove all the pus by irrigation.

One other point worth mentioning incidentally turned up in the discussion. Mr. HAWARD mentioned a case in which an unopened suppurating cyst caused the death of the patient, setting up fever and albuminoid degeneration of viscera. Mr. PEARCE GOULD mentioned a case of a large suppurating cyst which was unattended by any fever, and gave no sign of the purulent nature of its contents. There must be some explanation of the opposite results of an apparently similar condition. Is it that in one case the pus had wandered out of the cyst proper into the pleura or some other tissue, while in the other it was securely lodged within the parasite? But this is only one of many very interesting problems suggested by hydatid disease, the chief and most unexplained of all being the mode in which the parasite gains entrance to the human body.

THE President of the Local Government Board has filled the vacancy created by the death of Sir FRANCIS BOLTON, and has appointed an engineer to occupy this important office. It is convenient therefore at this moment to review the safeguards which London possesses against injury from so fertile a source of disease as contamination of water-supplies. Under the Metropolis Water Act of 1852, Section 4, every water company is required to "effectually filter all water supplied by them within the metropolis for domestic use before the same shall pass into the pipes for its distribution, excepting any water which may be pumped from wells into a covered reservoir or aqueduct, without exposure to the atmosphere, and which shall not be afterwards mixed with unfiltered water." In order to ensure the enforcement of this provision, the Metropolis Water Act of 1871 requires that "there shall be a water examiner, being a competent and impartial person from time to time appointed by the Local Government Board, who shall from time to time, in such manner as the Local Government Board direct, examine the water supplied by any company in order to ascertain whether or not the company have complied with the requirements of Section 4 of the Metropolis Water Act, 1852, and shall from time to time report the results of his several examinations to the Local Government Board; and that Board shall send a copy of every such report to the company to which the same relates; and the company may, if they think fit, on each occasion of such examination, be represented thereat by some officer, but such officer shall not interfere in the examination." The metropolis is therefore largely dependent upon filtration and chemical analysis for its preservation against water-carried diseases. Dr. BUCHANAN, in his Annual Report for 1881, summed up the position of chemical analysis as a safeguard against injury to health by stating that the chemist can tell us of impurity and hazard, but not of purity and safety, and this conclusion will undoubtedly be supported by those who are aware of the minute quantity of specific matter which is competent to produce injury to man. The evidence of mischief is, indeed, less readily found by the chemist than by the health officer, whose duty it is to discover the cause of outbreaks of sickness amongst those who are resident in his district. In London the machinery which would bring such illness to light is of so unsatisfactory a character that no substantial reliance can be placed upon it. The absence of any system of registration of disease is itself a noteworthy disadvantage; the division of London into some thirty-nine districts is again a serious obstacle to the investigation of any diseases which might be produced by the contamination of water-supplies. It is for this reason that we had hoped that the late Sir FRANCIS BOLTON'S office might be filled by the appointment of a medical man competent to perform such duties as we have indicated.

We are fully cognisant of the importance of engineering and chemical skill being brought to bear upon the control of water-supplies, but these touch but one side of the question, and nothing short of the exercise of watchfulness over the health of water consumers can give any guarantee of safety to those who in these matters are practically powerless to help themselves. The legislation of 1852 and 1871 could not have regard to this consideration; medical knowledge has grown since those times, and would itself be largely developed by continuous investigation into the effects upon health of water under different conditions. It has been too readily assumed that sewage when introduced into running water becomes oxydised in its passage down stream; doubtless there is much dilution of the impurity by the addition of other water, but it is difficult to say at what point below the intake of impurity the water regains its wholesomeness.

The drinkers of water supplied by the Thames have much ground for anxiety at the present time; the published reports of Sir FRANCIS BOLTON raise serious question as to the propriety of continuing those supplies which are derived from the Thames at a suspicious proximity to the localities of the discharge of sewage. Certainly, no health officer would be willing to accept as a sufficient basis for confidence the fact that water has been filtered, or that chemical analysis fails to detect impurity. The issues involved are of vital importance to Londoners, and cer-

Digitized by Google

tainly those who can exercise control in this matter ought not to leave the metropolis unprotected.

AMONG the proposals for reform in regard to the rules of procedure and customs of business in the lower House of Parliament, is one which must elicit the sympathy of the medical profession without respect to the party feeling or political principles of its members. We refer to the contemplated new rule that, "unless previously adjourned," the House shall "sit till half-past twelve of the clock at night, when the Speaker shall adjourn the House without question put." The phraseology in which this proposal is embodied is not remarkable either for English or elegance, but the idea is an excellent one. Half an hour after midnight is surely late enough for the making of laws. If we may not fall back on the old adage that "it is time for all good people to be in bed," it is an hour at which those who are engaged in work supposed to require fairly clear and energetic brain-functioning may, without any fear of being thought idle, avow themselves weary, and seek reliefand recuperation in repose. How very heavy is the fine imposed by Nature upon the class of public men who not merely turn night into day, but burn the candle at both ends by rising early and late taking rest, is too well known to those upon whom devolves the task of combating the advances of mind and body weakness and of fighting off death on behalf of the victims of this inexplicably mistaken policy. In the old days when the House first formed the evil habit which has come to be one of its cherished usages, early rising was not a practice to which the class of society from which members of Parliament were then commonly taken was much addicted. The legislators of the last century, and the early part of this, acted very much on the prudential principle enunciated by the late Lord BYRON and did not get up until the sun had warmed the world. We have changed all this, but with wondrous awkwardness and fatuity. We rise betimes, but do not go to bed any—or only a very little—earlier than did our great-grandfathers. This is bad enough when the muscular and general systems only are worked excessively, and the brain is practically allowed to lie fallow, as in the case of the man about town; but it is incomparably worse when the particular organ which most needs rest in sleep, and can only get it therein, is worked at the time when it ought to be slumbering.

It has been repeatedly urged that the work done by jaded law-makers at two or three o'clock in the morning connot but be less than the best of which the same minds are physically or intellectually capable. This appeal to the self-critical consciousness of our legislators in the first instance, and to the public, their constituents, in the second place, ought to be regarded as forcible; but, as a matter of history, it has not proved in a practical sense effective. The *argumentum ad hominem* may, perhaps, have greater success. Let it, then, be distinctly understood that recent Parliaments have shown a very serious percentage of brain-mortality—or, which is much worse, mind-ruin—as the result of late sittings which have to be endured after body and brain have been already wearied, if not exhausted, by a fair day's work in a Government office, in court, or with some tiresome occupation. It may be thought that such toil as members of the House of Commons have to face is not in itself very exhausting. That is a misconception, and it may readily be accounted for, because no one who has not personally experienced the weariness of habitually sitting out long debates can ever guess how the strength of body and mind is tried by the process. The time has passed, perhaps for ever, when the business of legislation in the Lower House was mostly left to the enterprise of younger sons of noble families and squires—in short, to men who could afford to be idle except in Parliament. The Commons of to-day are for the most part busy men, wholly apart from politics; and it is, therefore, more than ever desirable—we would say necessary—that a reasonable limit shall be put on the duration of sittings of the House. The Lords do not indulge in late hours, and seldom sit after dinner, except when questions of great moment or urgency are engaging their attention. It is with the Lower House we are chiefly concerned in connexion with the subject of "overwork," and we sincerely hope the very late hour (12.30 P.M.) selected by the promoters of this reform may be accepted as the limit at which measures for the enforcement of rest become publicly and personally indispensable.

Annotations.

"Ne quid nimis."

THE MEETING OF THE ASSOCIATION OF GENERAL PRACTITIONERS.

AT the meeting lately convened by the Council of the Association of General Practitioners debated questions with which the profession is now familiar were once more considered, and the resolutions passed respecting these may, alike in tone and matter, stand as guiding precedents in future discussions of the same character. The advantage of instituting a degree obtainable by London students on terms more reasonable than those required by the University of London was well brought out in a speech by Mr. Wheelhouse, the chairman on this occasion. Another question of considerable moment was not forgotten. In supporting the claims of the Apothecaries' Society, Mr. Wheelhouse and Mr. Wickham Barnes advocated no greater concession than the conjoint Colleges might conveniently grant, or, indeed, than it is incumbent upon them in respect to the expresed wish of the great body of their constituents to allow. The services rendered to the medical profession by the Society in the past call for some return, while to ignore its claims and the recognition afforded them by the last Medical Act can only tend to weaken the influence of the yet unborn conjoint qualification, which embodies the fairest promise which we now have of a common adequate professional status for London-trained practitioners in the future. The importance of the motion which was entrusted to Dr. Danford Thomas must be generally acknowledged. In asking for a representative voice in the government of the College of Surgeons the Members are seeking no more than their due, and it would be a graceful no less than a politic act on the part of the College of Physicians to afford recognition in a similar way to their Members and Licentiates. Personal representation as the counterpart of personal duty is the most characteristic feature of our national life. It is a principle than which none can be fairer. It is native and inevitable to every constitution composed of intelligent men, and, whatever its possible disadvantages, its history in the past has been marked by progress and prosperity. If the Councils of the Colleges have misgivings lest a deterioration of their professional

Digitized by Google

spirit or their qualifications might follow the application of this principle in their own case, we would bid them take confidence. Among their less prominent alumni are many men well able to appreciate the value of a high standard of professional education and practice, and it is not likely that their number will diminish. The Privy Council, it is satisfactory to learn, has interested itself in these proceedings. It engages to weigh the opinions of the Members, and we presume of the Licentiates also, before it ratifies any material change in the Charters of the Colleges. If, however, it should happen that ordinary measures fail to attain the desired object, the Practitioners' Association proposes to avail itself of other and more effectual help. The motion by Dr. Brierley asks for the appointment of a Royal Commission to inquire into the subject, and unless a request so reasonable can be turned aside by party influence, it is difficult to see how the claim for representation can fail to be conceded.

ALTERATIONS IN THE EXAMINATIONS AT THE UNIVERSITY OF LONDON.

WE are pleased to see, in the interest of the candidates, that the number of hours at the Matriculation Examination will be reduced from twenty-eight to twenty-five. They will now only be required to show a competent knowledge of one instead of two languages—viz., Greek, French, German, Sanskrit, or Arabic, in addition to Latin, and English language and English history, with the geography relating thereto. Mathematics; mechanics; and one branch of experimental science—viz., chemistry, or heat and light, or magnetism and electricity—are the science subjects carefully laid down to balance the classics. Experience has apparently proved to the authorities that chemistry can be taught at only few schools, and we venture to say that the other branches of experimental science will not be better taught. Moreover, if science has to be taught to schoolboys, why might not some choose one of the various branches of biology, which we, at any rate, believe to be more interesting and important? The only answer is that, however much boys may wish to prosecute such studies, teachers are wanting. But adequate teaching and instruments for experimental science exist in but few large schools and in the science colleges, and the preparation of the rest is *pure cram*. By cram we mean laying stress on a number of isolated facts without insisting on a knowledge of the principles which underlie them, or of the instruments by which they are demonstrated to exist. If the University of London were to insist on a sound knowledge of any one branch of learning—classics, mathematics, English, or an experimental science,—some advantage to real learning might result. Now it presents to the candidate merely an *olla podrida*, and cannot make up its mind whether its matriculation examination is the *terminus a quo* for its degrees, or the *terminus ad quem*, when the learning of the pupil is to come to a stop.

A practical examination with patients will be held in the Examination in Surgery at the M.B. Pass Examination. The recent visitation by the General Medical Council has led to the removal of one blot which was most forcibly insisted on by the official visitors. "There was no Clinical Examination; no operations were required on the dead subjects; no testing as to bandaging was employed; no recognition was required of surgical instruments or apparatus." Such shortcomings are simply and solely the outcome of the University regulations, and for them the examiners are by no means responsible. We think that other alterations on the lines suggested by the Visitors will have to be carried out, for the M.B. Lond. is a registrable qualification, and this must always include a sufficient examination in surgery as well as in medicine and midwifery, and as there are still a few students who do not present themselves to the corporations for examination, but are registered merely on their University degrees.

DEATH FROM CHRONIC LEAD POISONING

AN inquest was held recently at Islington touching the death of a woman aged about thirty-eight. Deceased had worked for many years at a white lead manufactory, and had from time to time suffered from "a touch of the lead,' or in other words had had "painter's colic." She is reported also to have indulged in alcohol, although the post-mortem examination failed to furnish evidence in support of the assertion. For some time before her death there had been weakness of the extensor muscles, yet this could not have been greatly developed, seeing that deceased had continued her occupation until within about ten days of her death. On the last occasion of leaving her employment she showed, in addition to her previous symptoms, signs of cerebral disturbance. As the latter became alarming she was removed from her home to the workhouse, where upon her admission she was found to be delirious. The delirium passed into insensibility, and this into death. She had no saturnine convulsions. At the necropsy the gums were seen to be bordered by a deep blue line, more deeply coloured on the dental than on the labial surface. The muscular coat of the intestines was greatly hypertrophied, though the bowel was not at all contracted. The colon was filled with solid fæces. The liver, spleen, kidneys, heart, and lungs were fairly healthy. The dura mater and arachnoid appeared normal. The meshes of the pia mater were filled with cloudy serosity, but there was no coagulated plasma, and none of that sulphur-like layer found in pronounced meningitis. The cerebral veins were full, but presented no evidence of ante-mortem blocking. In short, there was no intra-cranial disorder other than is found in cases of cerebral irritation from many other causes than lead-poisoning; nor, indeed, could the condition be better described than as what is commonly called "serous apoplexy." It is instructive to note that there had been no known disturbance of brain function attributable to deceased's occupation antecedent to her fatal illness. The surgeon engaged to attend the factory hands stated that 99 per cent. of the operatives had the blue line, and a man who gave evidence at the inquest, and who had only worked in lead for about three months over a period of three years, showed a decided discolouration of the gums. There was ample testimony to show that every precaution had been taken by the employers to protect their workpeople, both as regards legal imposition and voluntary action. We understand that there is the greatest difficulty to compel the operatives to habitually avail themselves of preventive treatment; but even allowing for this, we cannot help thinking that "white lead" making is still a dangerous occupation, and one alike calling for scientific aid and legislative enactment requiring regular medical inspection. The mere weekly attendance of a medical man is delusive in its supposed benefit to the workers in lead, for the existence of the blue line is not considered of sufficient moment to discharge operatives, and obviously many of them will rather conceal any slight subjective symptoms than run the risk of being invalided and so lose their source of income. We cannot subscribe to the opinion given by the medical man to the firm "that the blue line was not evidence of constitutional affection." It is true it may not be accompanied by other manifest signs or symptoms, but, for all that, it proves that the metal has been absorbed into the circulation, and that thus it may be slowly and silently working irretrievable mischief in the tissues—mischief which at any time may show itself in colic, palsy, or even in fatal activity in the brain. An analysis of portions of the liver, made by Mr. A. P Luff, showed traces of lead.

THE CLINICAL SOCIETY.

The address given by the new President to the Clinical Society on his taking the chair for the first time was, as such addresses are likely to be, eminently characteristic. The address showed a good many traits of Dr. Broadbent's mind; but it showed none better than this—his appreciation of, and interest in, all the branches of the great tree of medicine. He is not one of those who cry "Diagnosis, diagnosis, diagnosis," and then neglect the treatment. Neither does he sympathise with the anatomical to the exclusion of the clinical or experimental pathologist. Like the true practical physician, he believes that all the knowledge of a medical man should be utilised to the full for the benefit of the patient. His remarks on reducing the temperature by special antipyretic drugs struck us as particularly philosophical and practical. Who knows, indeed, what other actions antipyretics may possess? The other actions may be deleterious, innocuous, or harmless. It is tempting, but useless, to speculate as to the probable effect of antipyrin on other than thermogenetic functions. We require more actual knowledge of the action of these drugs on the nervous centres and heart. The value of presidents' addresses consists in their being historical, as well as ornamental, useful, and introductory. The medical historian of the future will find in these addresses a representation of the feelings and thoughts of eminent physicians and surgeons; he will also find in them indications of the aspirations of the times at which they were delivered, and of the special tendencies of knowledge.

THE ELECTION AT ST. BARTHOLOMEW'S.

The vacancy in the staff of St. Bartholomew's Hospital, caused by the resignation of Dr. Wickham Legg, is likely to prove the occasion of a severe contest. From the list which we append below it will be seen that the number of candidates is exceptionally large, for the system that prevails at this hospital of encouraging junior members to hold the temporary staff appointment of "casualty physician" necessarily lays open the office of assistant-physician to a considerable number of claimants. Many of the candidates, too, are well known for their scientific attainments and important contributions to medicine. Dr. Samuel West, who has been medical registrar to the hospital for several years, and medical tutor in the school, has very great claims, which we should like to see duly acknowledged. Amongst the many earnest and able workers in the ranks of young physicians, few have done so much both in clinical and pathological research as Dr. West. Dr. Percy Kidd, another candidate, is also favourably known for his contributions to pathology, especially in pulmonary disease. Dr. Ormerod is equally well known as a careful investigator in neurological science. Dr. Vincent Harris has done good work as a physiologist. Besides these gentlemen, there are others named more or less known outside the limits of their school, and the governors will have no little difficulty in making a judicious selection. We must emphatically protest against the retention in this hospital of the ancient method of election by the whole body of governors. It involves great hardship on the candidates, and places them in a humiliating position; whilst it by no means follows that the candidate who is best qualified will be elected. Surely it is time that this state of things were altered, and the election placed by the statutes in the hands of a select committee, which should exclusively consist of members of the medical staff, who alone are capable of forming a correct opinion of the merits of candidates. This plan is now adopted at many hospitals, and would, we feel sure, while it did away with the degrading canvassing whereby members of a learned profession have to stoop to solicit the votes of individuals who have no interest in or knowledge of what constitutes the real claim to a position on a hospital staff. Another suggestion has been made which is worthy of consideration—viz., that the staff on the medical side of St. Bartholomew's Hospital should be increased by the addition of a physician and an assistant-physician. There is ample room for such enlargement, and it would harmonise with the number of members on the surgical staff. If carried into effect, such a change would create two more medical vacancies, and there would be no difficulty in filling them from among the following names of gentlemen who are candidates for the post of Assistant-Physician, now vacant:—Oswald A. Browne, M.A., M.B. Cantab., M.R.C.P. Lond; Arthur Temple Davies, B.A., M.B. Cantab., M.R.C.P.; Archibald Edward Garrod, M.A., M.B. Oxon., M.R.C.P. Lond.; Samuel Herbert Habershon, M.A., M.B. Cantab., M.R.C.P. Lond.; Vincent D. Harris, M.D. Lond., F.R.C.P. Lond.; Wilmot Parker Herringham, B.A., M.B. Oxon., M.R.C.P. Lond.; Henry Lewis Jones, M.A., M.B. Cantab., M.R.C.P. Lond.; Percy Kidd, M.A., M.D. Oxon., F.R.C.P. Lond.; Joseph Arderne Ormerod, M.A., M.D. Oxon., F.R.C.P. Lond.; William Edward Steavenson, M.D. Cantab., M.R.C.P. Lond.; Howard Henry Tooth, M.A., M.D. Cantab., M.R.C.P. Lond.; Samuel West, M.A., M.D. Oxon., F.R.C.P. Lond.

DIPHTHERIA AT EALING.

A SERIOUS outbreak of diphtheria has occurred at Ealing The disease appeared at the close of the week ending January 22nd, and continued to increase until Thursday, January 27th, when fresh cases ceased to occur. In all up to the time named twenty-three cases were discovered, and three cases terminated fatally, one of them in the person of Mr. Charles James Fox Kenworthy, of Kerrison Lodge, The Park, Ealing, a gentleman thirty-four years of age, and very much esteemed. One of the remarkable features of the outbreak was that not a single instance of an attack was met with amongst the poorer classes—a fact which presupposes that neither water-supply nor drainage is accountable for the outbreak. The idea that milk is the source of the contagion seems pretty general, and Dr. Corfield has, we understand, been called in to inquire into the matter. He is reported to have inspected the principal dairy farm at Ealing in company with the medical officer of health, and after inspecting the ninety-six head of cattle on the farm, together with the cisterns, the drainage, and the sheds, has come to the conclusion that everything is unexceptionably good. The suggestion, therefore, is that if milk be the cause of the evil, it has been imported into the locality—a suggestion the more probable because such importation is rather extensively carried on. The whole subject is still under investigation, and as the elements of the problem are narrowed down to a few we should hope the solution of the mystery will be definitely solved.

UNIVERSITY OF EDINBURGH.

WE have hitherto studiously declined to enter into the painful details of the scandal now agitating the University of Edinburgh and, through it, the public. Everyone must regret to see a man in the position of Professor Rutherford bringing charges of a gross character against his assistant, and having to acknowledge them groundless and to retract them. We have no right to speak judicially, even if we had the means of investigating all the facts of the case; but we are all interested in the welfare and the fame and reputation of the University of Edinburgh; and we think it not only a discredit, but a misfortune, that no notice has been taken of this matter in its earlier stages by either the Senatus or the University Court. The Senatus is an exclusively professorial body. And it is a fault of the

Digitized by Google

University that all arrangements seem to regard too exclusively the interest of the professors. Scarcely from such a body could effective intervention have been expected. But the University Court is more responsible. It has powers of censure. In it the public, the graduates, the students, as well as the professors, are represented. And yet it has allowed this matter to grow to a height that is damaging to the reputation of the University and of the professor more immediately affected, to say nothing of his assistant. We shall want fresh guarantees in the new legislation for the Scotch universities against the recurrence of such scandals as this, and in favour of those assistants whose work is only second in importance to that of the professors, but whose emoluments are so small and so liable to discontinuance with the cessation of dignified relations with the professor. Even now, and with its present powers, the University Court ought to intervene, and it would satisfy the public that the University of Edinburgh is a school where scandal may not be raised with impunity.

AVIAN TUBERCULOSIS.

THE October number of the *Journal of Comparative Medicine and Surgery* (Philadelphia) contains an interesting article upon Avian Tuberculosis by Mr. Bland Sutton. The bibliography of this subject is comparatively small, and Mr. Sutton's contribution is therefore all the more welcome. The disease affects mainly, if not entirely, graminivorous birds, and its occurrence in birds of prey may often be attributed to their feeding on tubercular smaller birds. As an illustration of this in another class of animals Mr. Sutton cites the case of a python which died with tuberculosis of the liver, having been fed on fowls, pigeons, and ducks, "which are exceptionally liable to tuberculosis." The marked characteristic of avian tuberculosis is the selection of the alimentary canal and associated organs for the seat of the disease. Large nodular masses form in the intestinal walls, and may give rise to actual obstruction, or eventuate in peritonitis. The lymphatic vessels in connexion with the bowel are often dilated and plugged with caseous material; whilst the liver and spleen show abundance of miliary deposits, resembling in their early stages those produced by such parasites as gregarinidæ. The portal circulation in birds is peculiarly suitable for the secondary infection of liver and spleen. Microscopically, the tubercular nodules consist in early stages of a central focus of round and giant cells, with bacilli in and around the cells; in older nodules the caseous centre is surrounded by an epithelioid zone, and that by a "bacilliferous zone" in which large giant cells occur, and that finally by a zone of inflammatory cells. The bacilli, which are perfectly homologous with the bacillus tuberculosis of Koch, occur in vast numbers; and careful observation shows that in the liver they are arranged in masses corresponding with minute vessels, whose lumina they completely plug. Mr. Sutton finds here an illustration of "amœbic warfare," to which attention was first drawn by Metschnikoff, and subsequently by Mr. Sutton himself in his lectures at the College of Surgeons. The bacilli gaining entrance by the food invade the walls of the intestine, and thence enter bloodvessels, where they encounter leucocytes, which by fusion constitute "giant cells," and take up numbers of the bacilli. He compares the tubercular nodule to a battle-field, the older masses containing most giant cells and indicating the traces of the past struggle in the caseous débris of dead cells and the extending zones of contending cells and bacilli. The disease is probably propagated by contamination of grain with the excreta of affected birds; yet hitherto attempts to detect bacilli in the excreta have failed. Mr. Sutton, however, adduces collateral evidence in support of this, and gives some striking facts upon the propagation of disease among parrots and other birds from neglect and overcrowding. In conclusion, he points out that the high body-temperature of birds doubtless favours the luxuriant growth of bacilli within their tissues, and suggests the possibility that the tubercular bacillus may have been evolved from some harmless form, "and that its peculiar character of thriving best at a temperature equal at least to that of the human body was first acquired by being transplanted to a medium, the chief constituents being *animal excreta*."

THE SHOP HOURS BILL.

THE Shop Hours Act, 1886, came into operation at the beginning of the present year. The limitation expressed in this measure, though it does not err on the side of stringency, has achieved a definite good. Something has been done to restrict the almost incessant work which from week to week was telling with unquestionably serious effect against the health of many young men and women. It cannot be said that the allotted period, seventy-four hours per week, is unduly short. It might, we imagine, be still further curtailed in the case of a good many shops without serious injury to trade. We do not pretend that shop labour is at all times arduous. Both as regards muscular and mental activity it is often, no doubt, sufficiently exacting; but, apart from such considerations, the atmosphere of even large establishments is frequently by no means well adapted to the preservation of health. On this subject we have before spoken at some length, and need not therefore now discuss it further. One evident advantage possessed by this Act is the elasticity conferred upon it by granting power to local authorities to modify its provisions to a reasonable extent in conformity with the local fluctuations of trade; and since in any calling two-thirds of the voting strength must support a proposed alteration, there is reason to expect that this liberty will not often, if ever, be abused. The right of keeping open shop on Sunday is denied to all callings, except those of publicans, keepers of restaurants, tobacconists, and news-agents. Even these, perhaps, might without much public inconvenience be included within the terms of the Bill, provision being made if required, as in the case of chemists, for occasions of real emergency. It has been found impossible so far to apply in the working of the Shop Hours Act the costly machinery of inspection. We sincerely hope that no such system may be required, and that public opinion may act as somewhat of a substitute. Where business premises consist of shop and factory combined the inspectors appointed under the Factory Act are available, and the need of their services in such cases has unfortunately been proved by experience. There is a tendency on the part of some employers to use their workshop employés after the allotted work period to reinforce the staff of ordinary shop-servers. Such an abuse, it is obvious, can only be remedied by careful and frequent inspection. Having thus considered some of the leading features of the new Bill, it is hardly necessary for us now to speak at greater length upon it. Even in its present somewhat imperfect form it must relax considerably the too great strain of business life, and we are convinced that employers will find themselves repaid in the quality and amount of service rendered in the shorter period for the working time which they appear to have lost.

HEROIC DOSE OF TURPENTINE IN CROUP.

IN an obstinate and dangerous case of diphtheritic croup, which had extended into the larynx, after painting with boracic acid, and subsequently with a chloric acid application, without benefit, the child's condition becoming worse and worse, Dr. Lewentaner of Constantinople, before resorting to tracheotomy, remembering a paper by Demlow in which turpentine was recommended in these cases, determined to give it a trial, and s

Digitized by Google

administered with his own hands a teaspoonful of the pure oleum terebinthæ, giving after it some warm milk. In a quarter of an hour the laboured laryngeal breathing had given way to normal respiration sounds. That night the child slept well and was quite free from the brassy cough which had previously been present. The next morning he was quite lively and was found playing with his toys. All trace of false membrane had disappeared from the pharynx, which merely presented a reddened surface. Convalescence was rapid and uninterrupted. The turpentine, however, caused an eruption on the face, trunk, and extremities, having much the same appearance as the rash of measles but of a brighter red. The spots completely faded in two days, and were followed by no sign of desquamation.

THE REGISTRAR-GENERAL'S ANNUAL REPORT.

THE forty-eighth annual report of the Registrar-General has just been issued, and contains the detailed vital statistics of England and Wales for the year 1885. It is satisfactory to note that the usual delay in the appearance of these annual reports has been abridged by more than three months, which encourages the reasonable hope that the increasing portion of the public which is interested in the national health statistics may in the near future anticipate the publication of the Registrar-General's detailed annual report, at any rate before the close of the year following that to which its statistics relate. The Registrar-General of Ireland has set a good example to the Registrars-General of the other portions of the United Kingdom in this matter, for his report for 1885 was issued early in July last. On the other hand, the detailed report of the Registrar-General for Scotland for the year 1884 has not yet been issued. It is true that an approximate annual summary of the vital statistics of each part of the United Kingdom is published in various forms within a few weeks of the close of each year, but this does not lessen the force of the unquestionable fact that the value of all vital statistics depends in great measure upon the promptness with which they can be issued after the occurrence of the facts with which they deal. Great as is the interest attaching to the exhaustive series of tables contained in the Registrar-General's Annual Report for 1885, it is impossible to ignore the fact that at the present moment that interest is considerably discounted by the fresher interest felt in the summary of the figures for 1886, which is now due. The year 1885 completed the first quinquennium of the current intercensal decade 1871-80, and was, as the Registrar-General reports, "the fifth consecutive year in which the death-rate did not exceed 19·6, the lowest death-rate in any year previous to this quinquennium having been 20·3." The mean rate in these five years fell to 19·3, from rates that had steadily declined in the four preceding quinquennia from 22·6 in 1861-65 to 20·8 in 1876-80. It is impossible to doubt the substantial improvement of the public health implied by these figures. The great saving of life in recent years has been mainly due to decrease of child mortality, and of mortality from the principal zymotic diseases. At the same time it is eminently satisfactory to note, from the report now to hand, that while the decline of mortality in the five years 1881-85, compared with the mean for the whole registration period 1838-85, was most marked under thirty-five years of age among males, and under forty-five among females, the death-rate in the quinquennium at each of the twelve age periods was below this general average. This must be especially satisfactory to those who have refused fully to recognise the advantage of the decreased mortality in early life, because after middle life the death-rates continued to increase after the decline in the rate of child mortality, and of the gross death-rates at all ages had set in. The report just published contains some special and interesting statistics upon the marriage ages of bachelors in different classes and occupations; on the mortality from hydrophobia in England and Wales in the thirty-eight years, 1848-85; and upon the local age and sex distribution of mortality from diabetes in the thirty years, 1856-85. We shall have occasion to refer to these subjects in a further notice of the report just issued.

ACUTE SPREADING GANGRENE.

IT is not often that examples of this terrible and fatal disease are met with, improved methods of treating wounds and the wounded having almost effectually banished it from the list of surgical accidents during treatment. A short account of a case, which was admitted under the care of Mr. Sydney Jones at St. Thomas's Hospital, will therefore be of interest. The patient, a fairly healthy-looking man, aged forty-three, a gardener, who said he had previously enjoyed good health, fell, on Tuesday, Jan. 25th, and ran a rusty spike into his left leg, about four inches below the knee, making a long punctured wound upwards and backwards, wounding a vessel in the position of the anterior tibial artery. The hæmorrhage appears to have been easily arrested, and the man was sent home and put to bed by his medical attendant. He suffered severe pain in the leg until the Thursday morning, when it began to swell and the pain ceased; the swelling rapidly extended and the leg became discoloured. On Friday midday he was sent to the hospital, and was then very ill, but apparently unaware of his serious condition. The leg was swollen from the foot almost up to the groin, and emphysematous crackling extended, chiefly on the outer side of the thigh, to the hip, and downwards over the foot, which was cold and without sensation. The leg was gangrenous, the region of the wound very tense, cold, and purplish-black, with vesication. Above the knee there was brownish pigmentation of the skin, and this, like the œdematous swelling of the thigh, was most marked on the lateral aspects. His tongue was dry, pulse rapid and compressible, and examination of the urine showed the presence of much albumen. Amputation above the middle of the thigh was performed soon after admission, but the patient, who did well for a time, died somewhat suddenly on the following afternoon, four days after the receipt of the injury. There was slight emphysematous crackling in the subcutaneous tissue of the stump, and tenderness along the femoral vein on the morning after the operation.

WARMING RAILWAY CARRIAGES.

IT is very strange that the repeatedly urged proposal to warm railway carriages by a complete system of pipes heated with the waste steam and the hot air from the engine has not been carried into effect. There would be no serious difficulty and comparatively little expense in putting this plan in operation. At the moment we write it is warm enough for spring weather; a day or two ago the weather was wintry. The cold may return, and, if it should, we shall be shivering under burdensome rugs, even in first-class compartments, while those who travel by the more genial appliances of locomotion across the Channel are taking matters more easily, and, if not actually enjoying themselves—by reason of the intolerable slowness of even fast trains on the Continent—will be, at least, free from perils by chill; not, indeed, because railway companies across the silver streak are one whit more considerate of the comfort and well-being of their passengers, but because the weather being less severe, the ills and grievances of a railway traveller's life are less difficult to bear. It will be well if the companies begin to warm their carriages at once; if not, they must be compelled to do this small service to the

Digitized by Google

public. Meanwhile, let those who travel in cold weather insist on securing as many foot-warmers as possible in the compartment, and have them frequently renewed, so that the atmosphere of their carriage may have the keen edge taken off its icyness.

ANTIPYRIN IN PHTHISIS.

ANTIPYRIN has been shown to have various uses, but if the success which has been reported by Dr. Zakrzhevski in a paper contributed to the *Russian Military Medical Journal* attends the practice of other medical men, this drug will hereafter be looked upon as almost a specific. While under ordinary methods of treatment the mortality of phthisical patients in the Helsingfors Hospital was 50 per cent. during the eight months in which the antipyrin treatment has been carried out not a single case has proved fatal, many of the patients having, on the contrary, improved so decidedly as to be able to return to their homes. The author much prefers the hypodermic method of administering antipyrin, as the effect is produced in less than an hour, whereas when the drug is given by the mouth no effect is produced for from one to three hours. The action of antipyrin is to increase the force of the cardiac contractions, and so to raise the blood-pressure. In phthisical patients it slows the pulse, but never quite to the normal rate. It also slows and deepens the respirations, and the digestive functions are improved. No albuminuria or other sign of renal disturbance was observed. With regard to the dose Dr. Zakrzhevski finds that it should be regulated by the strength of the patients. In a man with phthisis, who was still fairly robust, a full dose of ninety grains was required in order to produce the best effect; whereas in greatly debilitated typhus patients ten or fifteen grains were quite sufficient, and in cases where there was decided exhaustion it was found that a dose of sixteen or seventeen grains was the largest that it was advisable to give.

A FATAL CASE OF SCURVY.

AN inquest held recently at Greenwich shows how narrow is the margin of protection afforded by lime-juice against outbreaks of scurvy when ships are ill-found or the crews unhealthy. In this case the patient, who died just on entering the Seamen's Hospital at Greenwich from syncope, embarked at Calcutta in the ship *Aladdin* on August 12th last. After nine days he showed symptoms of disease, which the captain thought was due to syphilis, and treated him accordingly, but it ultimately proved to be scurvy. Another member of the crew was also affected, but more slightly. Evidence was given which showed that the diet was confined to salt meat, bread, peas, rice, tea and coffee, and water, which was very bad. Such a diet would eventually lead to scurvy, and the date of the occurrence of the outbreak would depend upon the powers of the resistance of each individual member of the crew. The two men who were attacked probably had the seeds of the disease in them when they left Calcutta. We have repeatedly drawn attention to the fact that a very large proportion of crews are recruited direct from hospital. So long as they can pass muster before the agent, they are content to engage for the voyage. As Mr. Harry Leech used to say, more ships are lost through the unseaworthiness of the crews shipped than of the vessels themselves. It is certainly a strange anomaly, that while the captains of ships can have emigrants medically examined the crews are not inspected. The Board of Trade, too, is also responsible for the maintenance of the defective dietary still in vogue in the mercantile marine. In these days of cold storage fresh provisions could easily be served out during the whole voyage; but then the rules and regulations of the Board of Trade stand in the way, and fresh meat may not be substituted for salt, unless the weight of fresh meat is equivalent to the regulation allowance of salt, which is absurd; and it is quite unreasonable to expect owners, if they have already gone to the expense of putting up a cold storage-house, to pay the difference between one pound of fresh meat and one pound of salt—a difference of about 2¾*d.*, which would represent a considerable sum on a long voyage and with a large crew. Some time since a large shipping company proposed to introduce a fresh meat supply throughout their vessels, and at their request a well-known authority drew up a diet scale, in which he proposed to substitute twelve ounces of fresh mutton for every sixteen ounces of salt pork and beef allowed by the mercantile marine scale. This very reasonable proposition was not, however, accepted, and for a time the matter was allowed to drop. We hope, however, the Board of Trade will become alive to the importance of improving the dietary of the mercantile marine; with the improved methods of preserving and storing fresh provisions, there can be no excuse for adhering to the antiquated method of provisioning ships still adhered to. There is no reason whatever why the sailor should now be predisposed to scurvy any more than an agricultural labourer. Lime-juice, no doubt, is an excellent preventive, but it is an artificial resource, for if ships were provisioned in accordance with the opportunities now afforded by cold storage and hermetically sealed tins of vegetables, it would become unnecessary and useless.

THE GEORGE THOMPSON FELLOWSHIP IN MEDICINE.

THE conditions and regulations regarding this Fellowship of £100 yearly, founded by G. Thompson, Esq., of Pitmedden, have just been issued by the Medical Faculty of Aberdeen University. The object of the founder was to enable a Graduate in Medicine of the University to pursue further studies and researches at a foreign or some other British school of medicine or hospital. The Fellowship will be tenable for two years, will be awarded after the last term of graduation for the year, and will be open for competition to all who in that or the preceding year have passed all the examinations for graduation in the University. The examination for the Fellowship will be held early in July, will be conducted partly in writing, partly *vivâ voce*, and partly practically, and will be confined to three of the subjects of the medical curriculum.

MERCURIAL PERIPHERAL (?) NEURITIS.

CLINICAL, histological, and pathological facts grow apace in the subject of diseases of peripheral nerves. The number is great of morbid processes known to the clinical physician in which peripheral neuritis has been found. Alcoholism, tabes dorsalis, diphtheria, endemic neuritis (béri-béri), leprous neuritis, saturnism, mercurialism, typhoid fever, rheumatic fever, and probably other continuous fevers, including tubercle and phthisis, are all accredited causes of lesions of peripheral nerves. Many of these causes do not act equally on the whole length of a nerve. Curiously enough, the changes may occur at intervals in the length of a single nerve. This variety has been badly named "segmental." It contrasts strongly with the Wallerian degeneration of the whole length of the nerve, though in this degeneration the first part to undergo change is that next the point of section, not the terminal plate, which would be furthest away from the source of nutrition. M. Letulle communicated recently to the Académie des Sciences the results of some histological investigations into the conditions of the nerves in mercurial paralysis as experimentally induced in animals. The results are remarkable, and require further investigation. The alterations were segmental, as above explained,

Digitized by Google

and peri-axial, but not in the least inflammatory. The special character consists in the progressive destruction of the myeline sheath, with preservation of the axis cylinder, but without increase in the number of nuclei of the neurilemma. Letulle speaks of them as trophic changes. Clinically, mercurial paralysis differs from saturnine forms in the preservation of normal electrical reactions, absence of amyotrophy, and persistence of deep reflexes. But further minute study of these paralyses is certainly desirable in the light of most recent knowledge.

THE HOME SECRETARY AND THE CONVICT THOMPSON.

WE are glad to see that the Home Secretary has promised Mr. James that a careful inquiry shall be made into the facts of the case of Thomas Thompson, now under sentence of death in Durham gaol for the murder of his child at Gateshead. We have reason to believe that there are unmistakable proofs of melancholia in Thompson's family. If there are any cases of murder, more than others, in which it is proper, and indeed imperative, to investigate and give due weight to facts proving an element of insanity in the murderer, it is in such a case as Thompson's, where the murderer kills his own child. It would be painful indeed to see such a man executed without the fullest proofs that he had escaped the evil inheritance of his family.

CHOLERA AND QUARANTINE IN SOUTH AMERICA.

IS is quite evident that cholera is on the increase in South America. On the east coast Uruguay and the Argentine Republic are affected, the disease having commenced at the important ports of Monte Video and Buenos Ayres. Inland there has been a somewhat wide diffusion into the centre of the Argentine Republic and also as far north as Paraguay. At Monte Video the increase which is taking place is considerable. On the western coast of the continent the disease appears so far to be limited to Santiago. The first spread of cholera to South America is believed to have taken place in connexion with a very considerable emigration of Italians to the district of the River Plate; but it is not easy to determine which locality became first affected. The attitude of the several Governments concerned is thoroughly characteristic of nations wedded to the quarantine system. Each one begins by denying or minimising the news as to cholera, and then when all are alike infected they set up a rigid system of quarantine between themselves.

TREATMENT OF TYPHOID FEVER BY INHALATION OF COLD AIR.

M. A. SOKOLOFF, of the Military Hospital of Krasnoeesky, published some time ago interesting researches on a new method of treatment of typhoid fever. The author had remarked that the patients suffering from this disease who were placed in tents could without inconvenience respire air at a temperature of zero, and that coincidently the temperature of the body fell from 40° C. to normal. He was thus led to conjecture that inhalations of cold air might be employed with a therapeutic object in view. He experimented on twenty-three cases, and found that inhalation of air nearly at zero caused a more or less pronounced defervescence, though the action is, as might have been expected, less lively than with cold-air or cold-water baths, and is at the same time more transitory. He found that the action varied under different conditions, the defervescence being least from midday to 6 P.M., and greatest between the hours of 7 and 10 in the evening. The effects were less during the first fortnight, the defervescence effected being less than 1° C., and lasting for only an hour and a half or two hours, whilst they were greater after the first fortnight, the defervescence amounting to more than 1° C. and lasting for several hours. The duration of the inhalation was found to be of little importance, a *séance* of ten minutes' duration being equal to one of twenty minutes. The best time was from twelve to fifteen minutes. The defervescence was not in direct ratio to the temperature of the air inspired, and air at very low temperatures did not act any better than air at somewhat higher temperatures, because exposure to the former had to be curtailed. Depression or excitation of the patient diminished or suppressed the antipyretic action of the inhalations. The general effects of inhaling cold air were that the respiration was diminished in frequency by about four times in the minute, and became deeper; the pulse was lowered on the average six beats, and became more full. On the other hand, the skin and mucous membrane became less dry.

THE APOTHECARIES' SOCIETY AND PRESCRIBING CHEMISTS.

READERS of THE LANCET of Jan. 8th may remember the case of a chemist at Bedworth, named Homer, visiting and attending a child till it died. The facts were investigated by the coroner, and the jury found that the chemist had been guilty of a breach of the law in attending, prescribing, and giving a certificate of death. A correspondence has been sent to us by Mr. Upton, clerk of the Society, showing that the Society was ready to prosecute the chemist, and gave him notice of their intention to commence proceedings. Thereupon Mr. Homer pleaded to have the proceedings stayed, and promised that the Society should have no more occasion to complain. The Society then drew out a form of undertaking to be signed by the chemist, and agreed, on these conditions, to abandon proceedings. The Society deserves praise for action in this matter, and not least for its readiness to forbear on a promise of good behaviour, which we anticipated in our notice of the case. There are many culprits who have not given any such promise, who should not be so leniently dealt with.

SALICYLIC ERUPTION.

BURNING sensations in the skin, œdema of eyelids, and patches of bluish-red erythema were noticed by S. Rosenberg to follow the administration of four grammes of salicylate to a sempstress. A bullous eruption appeared on the site of the erythema as the result of continued use of the drug. Three days after the discontinuance of the drug the vesicles dried up. A fresh experimental observation was made, with a similar result. The urine gave a distinct ferric chloride reaction. The inunction of salicyl ointment was followed by burning and red patches on the skin with blueness of face, and the urine showed the salicyl reaction.

THE CRICHTON ROYAL INSTITUTION, DUMFRIES.

IT will doubtless be remembered that about the middle of last year Dr. Lennox, assistant medical officer at the Crichton Royal Institution, Dumfries, charged Dr. Rutherford, the medical superintendent of that institution, with subversion of order in the house, and also complained of the inferior quality and deficient quantity of the food supplies. The General Board of Lunacy held an inquiry into these charges, and the result of their investigation has been published. The conclusions which were arrived at are as follows:—(1) The charge of want of discipline is unfounded; (2) the statements made by Dr. Lennox respecting the food are undeserving of confidence, the supplies being satisfactory, although on a considerable number of occasions the cooking of the food appears to have been unsatisfactory

Digitized by Google

(3) that the estimate of the cost of the food is unsupported by facts, and shows an ignorance of the cost of the food of patients in other asylums; and (4) that the charges against the management were prepared and brought forward in a way which deserves strong censure. Two medical commissioners who visited the asylum at the request of the Board of Lunacy also reported most favourably of the discipline and food-supply of the establishment. The case has excited much local interest, and Dr. Rutherford is to be congratulated upon the result of the inquiry and the termination of an episode which must for some months have been a cause of considerable mental annoyance.

IMPENDING RUIN OF SPANISH PHARMACISTS.

La Vara de Esculapio states that since the beginning of July—that is to say during the last six months—nine pharmacies in Madrid have been closed, and that forty more will certainly follow their example before July, 1887; also that unless the present arrangements about military pharmacies are entirely changed an additional seventy will probably close at some subsequent date. If this prophecy comes to pass, the Madrid pharmacies will in a short time have been diminished by 109! In this country chemists have to compete with the stores and seem to have good reason to complain, but we never hear of such wholesale closures as are being carried out in Madrid, where, though the military pharmacies may to an unjustifiable extent supply civilians at something like cost price, as is alleged, no medical man thinks of such a thing as dispensing his own medicines. *La Farmacia Española*, referring to the subject, suggests that the doctors and pharmacists should combine together and demand the consideration of their rights from the Government.

UNIVERSITY EXTENSION IN SCOTLAND.

A MOVEMENT is at present in progress among the Scottish Universities for the organisation of systematic courses of extension lectures upon all departments of science and literature, similar in range and aim to those which were initiated in England upwards of twelve years ago by one of our best known educationists, Professor Stuart, M.P., and which have been so successfully carried on by the University of Cambridge, particularly in the mining and manufacturing districts of the north of England and the midlands. It is hoped in Scotland to overcome the difficulty of supplying regular and complete instruction, so far as the Universities are concerned, by uniting their available lecturing power; so that while any town would naturally in the first place be supplied, as far as possible, from the nearest University, any desired course might be drawn from a more distant one. The project of establishing "extension colleges"—i.e., centres of regular teaching—is already under consideration in several of the most important county towns and manufacturing centres throughout Scotland, especially in connexion with the local jubilee movements.

TUBERCLE INOCULATION DURING CIRCUMCISION.

DR. ELSENBERG, writing in a Polish medical journal, gives an account of a case where tubercular infection was conveyed to a child during circumcision through the filthy practice of sucking the wound. Several cases of this kind have been previously recorded by Lindmann and by Lesmann, who recorded ten instances of infection by one operator. The interest of this case lies chiefly in the doubt which at first existed as to the nature of the ulceration, which had very much the appearance of a chancre, but which on microscopical examination showed the existence of tubercle bacilli. The operator was apparently in pretty good health, having only a trifling cough, but tubercle bacilli were found in his sputum, and in the inter-arytenoid space some distinct tubercles were seen by means of the laryngoscope on an infiltrated base.

EPIDEMIC DIARRHŒA.

IT is unusual to hear of any epidemic prevalence of diarrhœa during the winter months, yet there is little reason to doubt that a large number of persons in London have during the last few weeks suffered from this malady, and this in a manner which raises a strong suspicion of community of cause. The subject is one that would likely enough escape attention, for the ailment is not of a character to influence death returns; nevertheless, diarrhœa is sometimes associated in its etiology with other diseases of a serious nature, and we cannot regard the appearance of groups of cases of this affection without some anxiety as to its meaning. Health officers would render valuable service by placing themselves in communication with medical practitioners in their district, for the subject is well worthy of investigation.

THE COSTS OF THE ELECTION OF DIRECT REPRESENTATIVES.

WE are asked to remind our readers that the costs of the election of Mr. Wheelhouse and Sir Walter Foster are still undefrayed by the contributions that have been received, and that subscriptions will be gladly received by Dr. Robert Saundby, Edmund-street, Birmingham.

DISPENSING BY MEDICAL MEN IN FRANCE.

IN the French Medical Bill, which has been drawn up and published, the old law which permitted practitioners residing in towns, villages, or communes where there was no chemist's shop to supply medicines to their own patients is now proposed to be altered, so that dispensing may be done only in cases where there is no chemist within four kilometres. Upon this *Le Practicien* remarks that it is to be hoped that all rural practitioners, who would simply be unable to exist under such conditions, will protest most energetically against this alteration, drawn up, as of course it is, by persons who have no knowledge of the conditions of medical practice in the country.

THE JACOB TESTIMONIAL.

IT is gratifying to observe that the Jacob Testimonial is likely to be a great success. The subscription-list includes the names of many eminent physicians and surgeons in the United Kingdom, whilst the popularity of the movement is shown by the support it receives from the rank and file of the profession.

THE BLOOD IN LEUKÆMIA.

DR. PRUS, a Polish observer, having studied the composition of the blood in five cases of leukæmia, writes (*Medycyna*, No. 39, 1886) that crystals of leucin are only found in the form of leukæmia which is accompanied with swelling of the glands. In general the number of Bizzozero's plates is very considerable, while the crystals of Charcot and Neumann are but seldom found. The movements of the white corpuscles are greatly increased.

DEATHS OF EMINENT FOREIGNERS.

THE following deaths are recorded:—Prof. Aug. Nonat, formerly a well-known and highly esteemed Parisian gynæcologist, in his eighty-third year; Dr. Antonio Garbiglietti, Dean of the Royal Academy of Medicine of Turin; and Dr. Pieter Hendrik Suringar of Amsterdam.

SMALL-POX IN AUSTRALIA.

NEWS from Melbourne is to the effect that, there having been no increase in the cases of small-pox amongst the passengers landed there and at Adelaide from the Nord-deutscher Lloyd steamer *Preussen*, those who were detained in quarantine have been released.

FOREIGN UNIVERSITY INTELLIGENCE.

Halle.—Dr. Oberst has been nominated Extraordinary Professor of Surgery.

Prague.—Dr. Emil Kaufmann has been recognised as Privat Docent in Otology in the Bohemian Faculty.

Vienna.—The Ministry of Education has addressed an inquiry to the Professorial Senate as to the necessity of establishing a third ophthalmic clinic—that is, one in addition to those under the charge of Professors von Stellwag and Fuchs. A committee has been appointed to report on the matter.

LECTURES will be delivered in Gresham College, Basinghall-street, E.C., on the Glands, on the 8th, 9th, 10th, and 11th inst., at 6 P.M., by Dr. E. Symes Thompson. The subjects of the respective lectures, which are illustrated by diagrams and free to the public, are the Structure and Function of the Absorbents; the Glands in Health and Disease; Diseases of the Glands; and the Surgical Treatment of Glandular Disease.

SEVERAL practitioners residing in and on the borders of the hamlet of Mile-end having consented to notify the occurrence of cases of infectious disease coming under their notice, the guardians have resolved to allow a fee of 2s. 6d. for each case so notified.

IN reference to the honour conferred on Prof. Billroth, to which we alluded last week, we may remark that the Vienna surgeon is the third medical professor who has in recent years attained the dignity of the Austrian peerage, the other two being Rokitansky and von Brücke.

SEWAGE SLUDGE.

THE best method of dealing with sewage sludge is one of the most pressing questions of the day. The importation of foreign guano has tended materially to reduce the expectation of any reasonable pecuniary return by the sale of sludge for the cost incurred by its separation from the fluid which accompanies it. Nevertheless, this removal is necessary in the interest of the purification of the effluents which now discharge into our rivers, and it may be hoped that the many experiments which are being carried on for this purpose may at last end in success. Mr. William J. Dibdin read an interesting paper last week on this subject, in which he pointed out that the solubility of a portion of the suspended matter in solutions of lime seemed to have been entirely overlooked; that the use of an excessive quantity of lime, while affording a rapid settlement of the sludge and a more or less clear effluent, dissolved a by no means inconsiderable quantity of the offensive matters previously in suspension. Chemical precipitation was incapable of removing more than a limited quantity of the oxydisable organic matters in solution in London sewage. Of the various chemical agents, sulphate of iron was superior to alumina for sewage purification, the latter being valuable chiefly for its effect in removing some of the colour from the effluent, but leaving the matters actually in solution. He regarded sewage sludge presses as a convenient mode for converting the sludge into a semi-dry portable form, but doubted the successful use of the material thus prepared, and said that, in place of the farm, in many cases the furnace appeared to be the ultimate destination of the offensive matter. In the case of the metropolis the conveyance of the sludge to sea was the only available remedy, but where local conditions were favourable, he refrained from saying other methods of disposal were undesirable.

Another paper by Mr. William Santo Crimp on Filter-presses for the Treatment of Sewage Sludge was also read at the same time, the author pleading for the filter-press as a ready means of disposing of the sloppy mass of putrescent mud produced daily in sewage precipitation works. He argued that the offensive and useless mass might be quickly converted into a practically inodorous manure, which was superior to ordinary farm-yard manure.

A very ingenious method of separating the liquid from the solid portion of the sludge was exhibited last week at Walthamstow, in Essex, where arrangements have been made for the application of Mr. Astrop's system of converting sewage sludge into dry powdered manure. At Walthamstow the sewage is run into a tank, where it is subjected to precipitation by lime, and, after the supernatant water is run off, the sludge is pumped into an adjoining building which contains Mr. Astrop's water-extracting machine. It is received first into a large sludge-vat, in which are two hollow perforated metal cylinders covered with fine wire gauze, and which are kept constantly revolving against brushes which keep the gauze clean; a partial vacuum is created in these cylinders by pumping, and about 60 per cent. of the moisture is extracted. The sludge then passes by a sluice valve on to an endless travelling web of wire gauze, having the same sized mesh as the cylinders, and occupying the whole width of the machine. The web is supported by rollers, and also passes under rollers, as well as over one of Körting's exhaustors, by which 10 per cent. of the moisture is removed. The sludge then passes between a series of rollers provided with scrapers, whence it falls into a hopper, and thus reaches a disintegrating cage on the lower floor; here it is exposed to a blast of warm air, and at the end of this process it contains but 5 per cent. of moisture. By this time it is in the form of a powder, which falls through the meshes of the disintegrator on to an Archimedean screw, and by this means is conveyed to a distance, where it is packed into bags. There is but little doubt Mr. Astrop's system will supersede other methods of fluid deprivation, and it can evidently be worked at a very small cost. The value of the product for manure is said to be considerable, but this must be determined more fully by future experience. The method is, however, a very convenient one; the machinery occupies but a very limited space, and is in every way inexpensive.

THE MEDICAL ATTENDANCE ORGANISATION COMMITTEE.

THIS Committee consists of the following gentlemen:—Chairman: Sir T. Spencer Wells, Bart. *Medical:* Dr. J. Ford Anderson, Dr. F. H. Alderson, Mr. E. C. Barnes, Mr. M. G. Biggs, Sir Andrew Clark, Bart., Dr. Alfred Carpenter, Dr. M. Corner, Dr. A. D. Ducat, Mr. W. G. Dickenson, Dr. J. Grey Glover, Dr. Alex. Grant, Dr. John Gordon, Mr. Ernest Hart, Mr. H. Nelson Hardy, Mr. Timothy Holmes, Mr. G. T. Keele, Dr. Alfred Meadows, Dr. W. M. Ord, Dr. H. Campbell Pope, Dr. Gilbart Smith, Dr. J. C. Steele, Dr. Walter Smith, Dr. G. Stoker, Mr. W. E. Steavenson, Dr. Dunbar Walker. *Lay:* Sir T. Fowell Buxton, Bart., Mr. W. Bousfield, Mr. W. G. Bunn, Rev. Canon Erskine Clark, Mr. H. N. Hamilton-Hoare, Lieut.-Col. Montefiore, Mr. F. D. Mocatta, Mr. Claude G. Montefiore, Rev. Geo. S. Reaney, Mr. C. J. Radley. Secretary: Mr. W. G. Bunn, 5, Lamb's Conduit-street, London, W.C.

The meetings of the committee, which are well attended, take place on alternate Tuesdays, from 4 to 5·30. So far not much has been done save to pass the following resolution:—"That any future plan for the medical treatment of the working classes should be conducted upon the principle of assurance, with a small fee at each attendance, or upon each prescription made up. Special terms should, however, be arranged for the admission of persons requiring immediate treatment, who should be compelled to join, and be expected, within one month of recovery, to continue as ordinary members, with the sanction of the medical officer under whom they wish to be registered." Such a resolution, of course, carries us but a little way in this difficult

Digitized by Google

question. All will agree that it is desirable that the payments of the working classes should be on the principle of assurance—i.e., that they should be periodical, in sickness and in health, in order that they may be of moderate amount, and most would agree to a little extra payment at each attendance or on the dispensing of medicines as a check upon the tendency to make frivolous demands on the medical men. The difficulty begins when we come to details and to formulate schemes and rates of payment which will really satisfy good general practitioners. All the recent attempts to organise medical attendance on the working classes have been more or less unsatisfactory, including those of the Metropolitan Provident Association. They have not improved on the demoralising notion prevalent among the working-classes that medical attendance is to be had for next to nothing. It could not be expected that medical men should identify themselves with an Association which at low terms took patients of all classes without respect to fitness. It remains to be seen whether any modification of the provident dispensary system can be got to work satisfactorily in London, where the conditions of life are exceptional. It is not proved yet that any new discovery works better than the old club system, supplemented by those accommodating terms on which medical men have always been ready to attend the humbler classes in the emergencies of sickness and disease.

THE VICTORIAN JUBILEE AND SANITARY IMPROVEMENT.

A PUBLIC conference was held at the Paddington Vestry Hall on Jan. 25th to consider proposals for commemorating the Jubilee. The following proposals were made:—(1) A recreation ground; (2) a public library and museum; (3) a town hall; (4) the Imperial Institute; (5) and the purchase of the canal basin and wharves, and the removal of the dust-collecting business from the parish. This last proposal had reference to the following motion, which Mr. Mark H. Judge intends to propose in the Jubilee Committee if sufficient support should be forthcoming from the inhabitants:—"That in the opinion of this Committee, the dust-collecting and other trades which are carried on in connexion with the canal basin between Warwick-crescent and Praed-street, besides being a continual menace to the health of the parish, are, during the summer months, a serious danger to the inmates of St. Mary's Hospital, and a source of annoyance to the Great Western Railway Terminus, which is so often visited by Her Majesty the Queen and the Ministers of the Crown; that the Committee, therefore, considers that no better memorial of the Victorian Jubilee could be devised in Paddington than for the Vestry to purchase the canal basin and adjacent property in order that this long-standing nuisance may be abolished and the site suitably utilised for residential and other purposes."

This scheme was supported at length by Mr. Mark Judge, and by Mr. Edmund Owen on behalf of St. Mary's Hospital.

NATIONAL HEALTH SOCIETY.

ON Friday evening, Jan. 28th, a meeting was held at the Paddington Baths to inaugurate a course of health lectures to be given by Dr. A. T. Schofield, under the auspices of the above Society. The meeting was largely attended and the audience representative of every grade of society, showing how general is the interest in the all-important subject of health. In the absence of Lord Randolph Churchill, who was detained in the House of Commons, the chair was taken by the Rev. J. C. Ridgway. Among the gentlemen on the platform were Sir Crichton Browne, Sir Spencer Wells, Dr. Priestley, Dr. Thorne Thorne, Mr. F. Treves, Rev. Dr. Clifford, and Mr. Shirley Murphy. After some introductory remarks by the chairman, Sir Crichton Browne addressed the meeting, dwelling on the importance of the work of the National Health Society in its efforts to prevent the origin and spread of disease by imparting knowledge through such lectures as Dr. Schofield's to all classes; Sir C. Browne also remarked that a special feature of these lectures would be the avoidance of technical terms and complicated expressions, and he went on to draw a favourable comparise between the physical condition of Englishmen and an other nation in the world.

Sir SPENCER WELLS pointed out that the average lengt of life was twenty years longer now than it was fifty yea ago; this he attributed to efforts at sanitary reform, such those of the National Health Society.

Mr. F. TREVES said the National Health Society wa strictly a missionary society, inasmuch as it appealed t individuals; in this he was supported by

Dr. THORNE THORNE, who said it was essentially th work of ladies to go among the poor, and to impress upo them both personal and general sanitary principles.

The Rev. MARSHALL TREDDLE and Rev. Dr. CLIFFOR spoke warmly in favour of the scheme of the propose Paddington Park.

Dr. SCHOFIELD then announced that the lectures woul take place at the Baths, at 8 o'clock on the following even ings:—Feb. 1st: Prevention of Disease. Feb. 4th: Eatin and Drinking. Feb. 8th: Use and Abuse of Stimulant Feb. 10th: Mind and its Culture. Each lecture will b followed at 9 o'clock by an ambulance lecture and demon stration; either course may be attended separately o together.

After a vote of thanks to the Chairman the meetin separated.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5933 birth and 3734 deaths were registered during the week ending Jan. 29th. The annual death-rate in these towns, whic had been equal to 26·5, 24·1, and 22·8 per 1000 in th preceding three weeks, further declined last week t 21·1. During the first four weeks of the current quarte the death-rate in these towns averaged 23·6 per 1000 and was 0·7 below the mean rate in the correspond ing periods of the ten years 1877-86. The lowes rates in these towns last week were 11·1 in Derby, 14· in Birkenhead, 16·2 in Salford, and 17·4 in Wolverhampton The rates in the other towns ranged upwards to 26·1 i Liverpool, 26·4 in Blackburn, 27·9 in Manchester, and 30·6 i Bristol. The deaths referred to the principal zymoti diseases in the twenty-eight towns, which had bee 485 and 392 in the preceding two weeks, further decline last week to 371; they included 130 from measles, 76 fro whooping-cough, 54 from scarlet fever, 41 from diarrhœa 37 from "fever" (principally enteric), 33 from diphtheria and not one from small-pox. No death from any of thes zymotic diseases was registered during the week in Derby whereas they caused the highest death-rates in Bristol Preston, Leeds, and Huddersfield. The greatest mortalit from measles occurred in Hull, Bristol, Leeds, and Hud dersfield; from whooping-cough in Halifax and Hudders field; and from scarlet fever in Sheffield, Bristol, an Salford. The 33 deaths from diphtheria in the twenty-eigh towns included 22 in London and 3 in Manchester. Small pox caused no death in London and its outer ring, or i any of the twenty-seven large provincial towns. Onl 1 case of small-pox was under treatment on Saturday las in the metropolitan hospitals receiving cases of this disease The deaths referred to diseases of the respiratory organ in London, which had been 731, 591, and 531 in the preceding three weeks, further declined last week to 432, and were 128 below the corrected average. The causes of 90, or 2· per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Portsmouth, Norwich, and Wolverhampton. The largest proportion of uncertified deaths were registered in Blackburn, Plymouth, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 29·9, 26·1, and 23·7 per 1000 in the preceding three weeks, rose again to 24·7 in the week ending Jan. 29th; this rate exceeded by 3·6 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·6 and 18·7 in Perth and Edinburgh, to 29·7 in Glasgow and

Digitized by Google

30·8 in Paisley. The 616 deaths in the eight towns last week showed an increase of 25 upon the numbers in the previous week, and included 19 which were referred to whooping-cough, 18 to measles, 15 to scarlet fever, 10 to diarrhœa, 7 to diphtheria, 6 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all 75 deaths resulted from these principal zymotic diseases, against 72 and 65 in the preceding two weeks. These 75 deaths were equal to an annual rate of 3·0 per 1000, which exceeded by 0·9 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 27, 26, and 20 in the previous three weeks, further declined last week to 19, of which 16 occurred in Glasgow. The 18 deaths from measles, of which 15 were returned in Glasgow, showed a marked increase upon the numbers in the previous two weeks. The fatal cases of scarlet fever, which had been 13 and 16 in the preceding two weeks, were 15 last week, and included 12 in Glasgow and 3 in Dundee. The 10 deaths attributed to diarrhœa, of which 6 occurred in Glasgow, exceeded those returned in the previous week by 3. The deaths referred to diphtheria and "fever" scarcely differed from the numbers in the previous week; diphtheria caused 5 in Glasgow and 2 in Edinburgh, and 3 of the 6 deaths from "fever" were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 213, 181, and 165 in the preceding three weeks, further declined last week to 155, and were fewer by one than the number returned in the corresponding week of last year. The causes of 80, or nearly 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 36·2 and 33·2 per 1000 in the preceding two weeks, further declined to 28·2 in the week ending Jan. 29th. During the first four weeks of the current quarter the death-rate in the city averaged 32·0 per 1000; the mean rate during the same period did not exceed 22·7 in London and 22·4 in Edinburgh. The 191 deaths in Dublin last week showed a further decline of 27 from the numbers returned in the two preceding weeks, and included 6 which were referred to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 4 to whooping-cough, and not one to measles, diphtheria, diarrhœa, or small-pox. Thus the deaths from these principal zymotic diseases, which had been 21 and 13 in the preceding two weeks, were 14 last week; they were equal to an annual rate of 2·1 per 1000, the rates from the same diseases being 1·9 in London and 1·2 in Edinburgh. The fatal cases of scarlet fever, which had been 8 and 4 in the previous two weeks, rose again last week to 6; and the deaths due to fever and to whooping-cough showed a considerable increase upon the low numbers in the preceding week. The deaths both of infants and of elderly persons showed a further decline from the numbers in recent weeks. Five inquest cases and 5 deaths from violence were registered; and 47, or nearly a quarter, of the deaths occurred in public institutions. The causes of 35, or more than 18 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Surgeon-Major John Godfrey Rogers, M.B, Medical Staff, has been appointed a member of the Distinguished Service Order for operations in the Soudan.

Surgeon General R. Lewer left England on the 27th ult. for Hong-Kong, to take over the appointment of Principal Medical Officer to the British troops stationed in the China command.

Staff Surgeon Parke left Alexandria on the 3rd inst., to join Mr. Stanley's expedition for the relief of Emin Pasha.

ADMIRALTY.—Deputy Inspector-General of Hospitals and Fleets Dugald McEwan, M.D., has been promoted to the rank of Inspector-General of Hospitals and Fleets in Her Majesty's Fleet, and has been appointed Honorary Physician to Her Majesty, vice — Salmon, deceased.

The following appointments have been made:—Fleet Surgeon Henry C. Woods, to the *Victoria and Albert;* Staff Surgeon Alfred E. Delmege, to the *Osborne;* Staff Surgeon Richard J. Barry, to Portsmouth Dockyard, and Staff Surgeon Henry T. Cox, to the *Duke of Wellington*, additional.

ARTILLERY VOLUNTEERS.—5th (Isle of Wight, Princess Beatrice's) Volunteer Battalion, the Hampshire Regiment: Acting Surgeon T. Q. Wiley resigns his appointment.—5th Surrey: Acting Surgeon W. A. F. Bateman to be Surgeon.

Correspondence.

"Audi alteram partem."

THE UNIVERSITY OF LONDON AND ITS NEW REGULATIONS.

To the Editors of THE LANCET.

SIRS,—Dr. Harris, in his letter in THE LANCET of Jan. 29th, has opened up a question of great import to those proceeding to graduate in medicine at the University of London. From the first appearance of the new regulations, in August of last year, we have anxiously awaited some higher power than ourselves to take up the cudgels on our behalf. It has been stated that the regulations in regard to the competition for honours at the Preliminary Scientific Examination (which are practically the same as those recently issued for the Intermediate Examination in Medicine) have worked satisfactorily, and from this it has been argued—upon very scanty data—that there will be a successful result from the new rules for the Intermediate Examination. But the difference between the two examinations seems to us most apparent. At the former the candidate usually presents himself before he has entered a medical school, and, the subjects being not strictly medical, he has no very strong wish to gain honours, and therefore does not run the risk of a failure. But, in the latter examination, there are subjects—anatomy and physiology—in which he will greatly covet honours; and yet, if he essays to secure them, he has to imperil his pass in the whole examination, and perhaps in the end will be only "recommended for a pass," in which case no record of his proficiency in the other subjects of the examination will be made. No student, after two years' work, will now be able to compete for honours without the misgiving that he may lose six months of his most precious time on account of his desire to acquit himself well at this very important examination. Is this the manner in which to encourage a high standard of work? If one paper only *must* be given, let it comprise a certain number of "honour" questions, which could be answered or not at the discretion of the candidates; or let there be a return to the old regulations. This letter, we believe, bears out the feelings of the majority of those who are now studying for their degree.

We are, Sirs, your obedient servants,

SIX UNDERGRADUATES OF THE UNIVERSITY OF LONDON.

Feb. 1st, 1887.

TREATMENT OF HYDROPHOBIA WITH THE POISON OF THE VIPER.

To the Editors of THE LANCET.

SIRS,—In my studies of hydrophobia I have been interested to observe how frequently of late curious methods of treatment have been proposed which have been considered original by those who advocated them, but which are simply resuscitations of old and discarded methods. I have not thought it important before to criticise any of these because they seemed to receive but little attention; but I have very recently seen in so many medical journals in America and in Europe recommendations of the employment of the sting of the viper as a preventive of hydrophobia, that it seems worth while to point out two facts: first, that the suggestion is by no means new; and second, that it has been tried and found wanting, and has been very properly abandoned.

More than a hundred years ago, in 1784, M. de Mattheis, surgeon to the King of Naples, seeing a dog said to be mad, and which went into a convulsion when water was offered it, bethought him of a viper which he had with him, and let it bite the dog's throat. The dog's head swelled immediately, the dread of water ceased, and the dog recovered.[1]

[1] See London Medical Journal, vol. v., p. 220, 1785.

Digitized by Google

In 1788, Fabbroni[2] reported the case of a man supposed to have hydrophobia, who was treated by the application of a viper to each of his legs. The patient seemed to be relieved for a moment, but died in half an hour.

These are the only cases I can now recall in which this astounding method of treating hydrophobia has been carried out, and it cannot be considered strange that it is not at present generally adopted. Other curious methods of treatment may be found described in many books on hydrophobia and rabies, and not a few are included in a paper on "The Treatmen of Hydrophobia Historically and Practically Considered," which I read before the American Medical Association in 1884, and which was published in the journal of this Association on Aug. 16th of that year. A reference to some of the books referred to, or to the paper just mentioned, would save some writers from error as to the originality or practicability of the methods which they propose for the treatment of this disorder.

I am, Sirs, yours respectfully,

Philadelphia, Dec. 25th, 1886. CHARLES W. DULLES, M.D.

RECENT PASTEURIAN DEATHS.

To the Editors of THE LANCET.

SIRS,—In the tables appended by your Paris Correspondent to his most interesting letter in your last issue, I find that Arthur Wilde who died at Rotherham after being treated at Paris is stated to have died of pulmonary disease. This is not correct. According to the account given in the *Rotherham Advertiser* the man was mortally ill before any symptoms of lung affection showed themselves, which occurred only a few hours before his death. It was stated that the remains of an old lung affection were found after death, but this could not have been the cause of death. His mother, who nursed him, who is a woman of great intelligence and the matron of an orphanage, assured me that he had nothing wrong with his lungs since he had an attack of pneumonia in his childhood, and that he had enjoyed excellent health afterwards. Her description of his case agreed with that given in the *Rotherham Advertiser*, and also with the description of the cases related by Professor Peter, especially in the commencement of the symptoms at the seat of inoculation—the intense prostration and some frothing at the mouth. These are not the usual symptoms of "congestion of the lungs," of which he is said to have died—indeed, the term is too vague for scientific use; there could have been no pneumonic consolidation, or that would have been mentioned. I observe by the table that M. Pasteur acknowledges the death of Smith, or Goffi, who died at St. Thomas's Hospital to have been due to hydrophobia, though at the inquest the question was left in doubt. It is reported that the rabbits inoculated from Goffi's spinal marrow died of rabies in seven days. According to the statement of M. Pasteur, made after the death of Louise Pelletier, this would prove that the inoculations were the cause of death, and would greatly strengthen Prof. Peter's case. At any rate the facts should be made known without delay, in order, on the one hand, to remove suspicion from M. Pasteur's treatment, or, on the other hand, to warn possible applicants against the risk it involves.

I am Sirs, yours truly,

JOHN H. CLARKE, M.D.

St. George's-terrace, Gloucester-road, S.W., Jan. 31st, 1887.

THE QUEEN'S JUBILEE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Will you permit me to say a few words in reply to Mr. Cheyne's letter, inasmuch as I wish to correct a most important error which I am sure he has inadvertently made—viz., that the proposed hospital is only for the treatment of diseases of the "throat, ear, skin, eye, rectum, &c.," whereas he has omitted to mention "orthopædic surgery" in all its branches, which will, of course, include diseases of the "spine and joints." There is also connected with this institution a surgical appliance department, for the purpose of supplying various mechanical instruments to distressed persons on their obtaining the requisite number of letters from the subscribers to this department, and I venture to think that this branch (surgical appliance department) is most important and of absolute necessity to the poor, who abound in thousands in the immediate neighbourhoods, such as Chelsea, Fulham, &c., who cannot afford the time to obtain such articles from more distant institutions. It was this branch that induced the promoters to add to the programme most of the special organs for treatment, such as the throat, ear, skin, and eye, and to these they have since added a department for the treatment of disease of the nasal and pharyngeal cavities by the most advanced methods, as beyond the cost of a few inexpensive drugs, the same establishment and employés can be utilised for carrying out the latter, and the medical staff is, of course, honorary. With regard to the in-patients, though the number of beds is somewhat limited, there is every prospect of success of adding more, as a great many influential persons have already promised their support, but who do not and will not contribute to other charitable institutions, for the reason that they are not allowed any privilege with regard to the internal administration of such beyond a few patient's letters of recommendation. Another all-important item is that, by the establishment of this institution, it will afford opportunities to many medical men to become attached to a hospital, and so develop "latent talent which would otherwise lie dormant."

In conclusion, I beg to state that this hospital will be governed by a committee consisting of an equal number of lay and medical members, and that by strictly adhering to all matters of professional etiquette and economy the Queen's Jubilee Hospital will, I hope, be an ornament to the profession.—I am, Sirs, your obedient servant,

THE SECRETARY.

The Queen's Jubilee Hospital, Gloucester-terrace, Queen's-gate, S.W., Jan. 1887.

*** We are still decidedly of opinion that such a hospital is not needed.—ED. L.

HOSPITALS, THE SICK POOR, AND ALL ENGLAND.

To the Editors of THE LANCET.

SIRS,—In a kindly notice of Sir Andrew Clark's original proposal, formulated in a scheme over my signature in *The Times*, for affiliating every parish, congregation, village, or hamlet through its clergyman, minister, local doctor, or other representative, with the Hospitals Association, by the formation of a Hospital Society, you have misunderstood the proposal in one important particular. It is not desired nor will it be attempted, to assume a kind of Providence over the provincial sick, and to invite them up to fill our London hospitals. On the contrary, the provinces will be left to look after their own sick poor and hospital administration, and all that we propose to do is to bring our intimate connexion with metropolitan and provincial hospitals to the aid of those who come in contact with the sick poor in all parts of England, with the object of locating difficult cases of disease or infirmity in the most suitable institution that may be available, always giving the preference to the one which is easiest of access to the particular case which needs such assistance. The scheme has excited very general interest; the conference in May, under the presidency of Sir Andrew Clark, promises to be a genuine success; and, as the proposal aims at aiding all the hospitals by exciting a wider interest in their work among all classes of the people, Sir Andrew Clark or myself will be very glad to hear, or to receive offers of co-operation, from any member of the profession who may wish to know more of our proposals and intentions.

I am, Sirs, yours truly,

The Lodge, Porchester-square, W. HENRY C. BURDETT.

THE MERE PRESENCE OF BLOOD IN THE PERITONEUM NOT A REASON FOR ABDOMINAL SECTION.

To the Editors of THE LANCET.

SIRS,—The novelty and importance of such a question as that dealt with in your leading article on pp. 227-228 induces me to trespass again on your extreme goodness to me in the matter of space in your columns.

I shall pass over the strong objections to the conclusions of Dr. Hunter's thesis as afforded by what we see in the human peritoneum, which proves conclusively that its

[2] Ibid., vol. ix., p. 69.

Digitized by Google

functions and its pathology differ most materially from those of the peritonea of rabbits and dogs. I wish only to point out that there is a vast difference between the mere presence of *blood* in the peritoneum artificially injected and the presence there of a *bleeding point*. It is the latter and not the former which demands prompt surgical interference, and in the presence of which the expectant treatment is absolutely criminal. No experiments on the lower animals can help us in deciding how to stop the bleeding from a ruptured tubal pregnancy, for no animal except the human is known ever to be the subject of such an accident.

I am, Sirs, yours truly,

Birmingham, Jan. 29th, 1887. LAWSON TAIT.

TYPHOID AND HYDRANTS.

To the Editors of THE LANCET.

SIRS,—In your issue of Jan. 8th there appears a paraphrase of a letter by Dr. H. Ward on Water Hydrants. I beg to point out that in publishing this Dr. Ward exceeds the bounds of professional etiquette. I, as medical officer of health for the Cowpen District, should have received some intimation of such "inquiry" and letter. I have refuted the assertions brought forward in this letter, which was published in several of the local papers, and written in a very offensive style. The Local Government Board requested a special report from me on the prevalence of typhoid during 1885, which I forwarded to them with the suggestion about the hydrants. They have taken no notice of the latter, and have asked me to report to them upon the carrying out of my recommendations. I attributed the epidemic of last year to wind-pressure upon the open outfalls of the sewers forcing the drain-traps. The epidemic of 1884 I proved conclusively to be caused by sewage pollution of one of the heads of the water-supply, which I condemned. I made seven quantitative analyses of the water and sent them to the Local Government Board, and they confirmed my decision.

I am, Sirs, yours truly,

R. LAING, M.R.C.S., L.R.C.P.,
Medical Officer of Health, Cowpen District.

Northumberland, Feb. 1st, 1887.

RELIEVING THE DUKES.

To the Editors of THE LANCET.

SIRS,—The year before last 148 cases of typhoid fever were treated at St. Bartholomew's Hospital, and 118 at St. Thomas's; and it seems probable that at all the London hospitals 1000 cases of typhoid are treated annually, at a cost of about £16 each. Now, since the Metropolitan Asylums Board is required by law to take charge of all cases of fever arising among the London poor, it follows that by admitting these cases the hospitals are relieving, not the poor, but the rates; and, further, since it does not matter to a man how much of his total for rent and taxes is rent and how much taxes, the only effect of reducing rates is to increase rents, and the hospitals are really benefiting the landlords to the extent of £16,000 a year. A better course would be for the hospitals to contract with the Asylums Board for the care of their typhoid cases; they could do the work cheaper and better than the Board can do it for themselves, and the cases would be available for clinical instruction. Especially is this course advisable at the present time, when so many beds are standing vacant for want of funds—not less than 300, I am told, at Guy's and St. Thomas's

I am, Sirs, your obedient servant,

X.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

PROPOSED CHILDREN'S HOSPITAL AT GATESHEAD.

The proposal to have a Children's Hospital at Gateshead has been for some time before the public, and we all thought the matter had been settled as far as the project was concerned; indeed, a considerable sum has been collected, and a site for the building granted free by Lady Northbourne, when all of a sudden a letter appears in our local papers condemnatory of the whole thing, and from a strong but very unlooked for quarter—namely, the Rector of Gateshead, who contends that there is no need for a Children's Hospital, and that the proposal is both wasteful and extravagant. This, I think, will not accord with the experience of Newcastle hospital surgeons, for they know that Gateshead children and adults crowd the waiting-rooms of the various hospitals on this side of the water. The Rector's contention is perhaps true, but true only in one aspect—namely, that the Gateshead poor obtain medical aid in Newcastle which ought to be provided in their own town, and that the subscriptions received by the Newcastle hospitals from Gateshead are in no way commensurate, so that it could hardly be considered a commendable economy to ask the town's-people to continue to send us their sick poor, to the saving of pockets at their side of the river. Dr. William Mearns of Gateshead has put the matter very forcibly in a capital letter in answer to objections, and which has appeared in our local papers. He says: "The population of Gateshead is over 70,000, that 90 per cent. belong to the working classes, and at least 25 to 30 per cent. live constantly from hand to mouth, and are in consequence obliged to apply to some charity for medical relief when overtaken by illness. The only medical charity in Gateshead is the Dispensary, which has no accommodation for in-door patients. As a medical man residing and practising in Gateshead for some considerable time, and as one of the honorary staff of the Dispensary, I give my emphatic testimony of the *absolute need* of a great many of the children treated by the staff of that institution being removed from the miserable and wretched conditions under which they live and their polluted surroundings, so as to be treated with any chance of a safe and speedy recovery." Dr. Mearns adduces many other reasons in his forcible letter why Gateshead should have a hospital of its own.

THE LATE MR. G. M'COULL, SURGEON OF OVINGTON.

The late Mr. M'Coull of Ovington, Northumberland, died very suddenly of heart disease when in active practice last April, and his many patients and friends have erected a monument to his memory in the cemetery. The design is of obelisk form, with massive plinth, and its height is sixteen feet. The inscription is in bold Egyptian characters, recording his age, and that "the monument was erected by a large number of patients and friends as a tribute of respect and in remembrance of many kind services rendered by him."

TRIPLETS IN NEWCASTLE.

A few days ago a poor woman was delivered of two girls and a boy by Dr. Farquharson, of Westgate-road. It may be mentioned that this is the third case of triple birth taking place in the Westgate district of Newcastle within the last eighteen months—Mr. John Foggin, a young surgeon here, if I mistake not, having attended two of these cases, which followed each other very closely.

Newcastle-upon-Tyne, Feb. 2nd.

EDINBURGH.

(*From our own Correspondent.*)

PROFESSOR HAMILTON AT THE ROYAL SOCIETY.

AT the last meeting of the Royal Society Professor Hamilton of the University of Aberdeen read a paper entitled "The Conducting Paths between the Cortex of the Cerebrum and the Lower Centres in relation to their Function," and exhibited a large number of sections and drawings illustrating his views on the subject. He defined in the first place the generally received view of the corpus callosum as a commissural structure. In contrast with this he stated the opinion that such is not the case, but that it is constituted by strands of decussating fibres derived from the cortex of either side and passing to the basal ganglia of the opposite half of the cerebrum. The apparent tendency to turn upwards at the lateral extremities of the corpus callosum depends on the necessity for the fibres to pass over the roof of the lateral ventricle before turning downwards to divide into the inner and outer capsules, which Dr. Hamilton describes as their real destination. Having referred to Foville's views on this point, which closely coincided with his own, Dr. Hamilton

Digitized by Google

laid down three postulates which must be fulfilled before his view could be proved beyond dispute. They are, first, a naked-eye demonstration by means of the scalpel, showing the course of fibres that he indicates; second, the same shown by transverse vertical sections of the brain; third, a microscopical demonstration that the fibres of the inner capsule and those of the corpus callosum are coterminous. All these, he claimed, were established by the specimens displayed, the third point being most difficult of demonstration, since the fibres do not run transversely, but obliquely, either from behind forwards or from before backwards, in their passage across the corpus callosum from the cortex of one side to the basal ganglia of the side of the cerebrum.

A NEW CENTRE WITH A CORRELATING FUNCTION.

In referring to the formation known as the branching neuroglia, Professor Hamilton stated his opinion that it is a delicate plexus of nerve fibrils. It is present in the grey cortical matter, also in the white matter of the centrum ovale; and a specially dense collection of these fibrils is found internal to the upper part of the inner capsule in the vicinity of the lenticular nucleus. This Professor Hamilton proposes to call the "plexiform nucleus." He assigns to it a function of great importance as a correlating centre.

THE FUNCTION OF THE THALAMUS OPTICUS.

Many of the fibres passing across the corpus callosum end in the thalamus opticus, and form a large part of that body, placing it in direct communication with the cortex of the opposite hemisphere. It has, however, little or no direct connexion with parts below, none whatever through the peduncles, as has been thought. Its main relations in other directions are those which it bears to the optic tracts, with which it is continuous. From these facts Professor Hamilton draws the inference that the optic thalamus is a communicating centre of association, relating other functions to that of sight; through it nearly all the special sense centres receive their education, their functions being here correlated with visual impressions. In support of this view, and of the anatomical details upon which it is based, reference was made to cases of destruction of the corpus callosum, in which it is found that education of the higher centres does not take place, since they are cut off from the influence of the optic thalamus. Where, however, the corpus callosum is congenitally absent, not having been destroyed, decussation takes place lower down than its normal site, and education of the higher centres is possible, and in fact takes place. When education is complete, the function of the corpus callosum as a channel for transmitting educating impulses falls into abeyance; this explains why injury to the corpus callosum late in life does not result in idiocy, as it does when occurring during childhood.

THE RELATION OF NERVE CELLS AND NERVE FIBRES.

As the result of continuous observations upon this point, Dr. Hamilton has come to doubt whether nerve fibres ever enter nerve cells, unless perhaps in the motor areas. He thinks the fibres form a kind of capsule around nerve cells, but do not become actually continuous with them. In regard to this point, it was stated by Dr. Bramwell, in the discussion which followed the paper, that in the anterior horn of the spinal cord there is direct continuity between the nerve cells and the delicate fibrils of that region, the latter being in turn aggregated into fibres. The same probably holds true of motor areas of the cortex; and if there, presumably also in sensory areas. Some such arrangement is demanded by what is known of the conduction and insulation of nerve impulses, and although, as stated by Professor Hamilton, there seems to be conduction apart from continuity in the ear in the relation of the sensitive to the conducting structures, yet in the eye it is found that actual continuity exists between the rods and cones and the nerve fibrils which convey visual impressions. Dr. Bramwell also criticised Professor Hamilton's paper in regard to the views put forth relative to the corpus callosum, and the plexus of nerve fibrils supposed to have a correlating function. Since the object of a nervous mechanism is to conduct as directly as possible nerve impulses to the seat of their realisation, such a plexus interpolated in the path could only complicate the matter very seriously. On the morning following the discussion Professor Hamilton gave a demonstration of his large collection of specimens in the hall of the Royal Institution, at which a large audience was present.

THE EDINBURGH PATHOLOGICAL CLUB.

This new medical society, formed for the informal discussion of medical and pathological topics, has already attained to vigorous vitality. At its second meeting, held in January, there was a plethora of interesting communications, and the limited number of members who form the club speak highly in praise of its efficiency as an arena where new ideas may receive such treatment as fits them for a wider field of battle, or devitalises them once for all.

Edinburgh, Feb. 2nd.

GLASGOW.

(From our own Correspondent.)

ANNUAL MEETINGS.

THE time for the annual meetings of most of the charitable institutions of the city has again come round. One of the most important was that of the

ROYAL INFIRMARY.

The meeting was held a few days ago, when it was reported that the number of patients treated in its wards during the past year was 4884, as against 4943 in the year preceding, and 5300 in 1885; taking the average of five years, the number of patients availing themselves of in-door treatment had fallen off to the extent of about 10 per cent. This seems to indicate a less amount of ill-health or serious accident in Glasgow during the past twelve months than for several years before. As to death-rate, excluding deaths occurring within forty-eight hours of admission, it was found to be 6 6 per cent., as against 7 5 per cent. in 1885. Those treated in the dispensary numbered 39,250, a decided increase on previous years. This, however, is understood to represent the number of consultations, and not that of new patients. The infirmary paid its way throughout the year, and put £265 to capital account. The meeting was rendered particularly interesting and lively by an account given by an infirmary champion of the manner in which its medical school had been founded. Prominence was also given at this meeting to the infirmary's proposal that the school should be erected into a college of Glasgow University—a plan which, if carried out, would probably relieve the directors of a very burdensome white elephant.

GLASGOW EYE INFIRMARY.

At the annual meeting of this very deserving charity it was reported that the number of cases treated during 1886 was 13,701; of these, 983 were in-door patients. This infirmary has recently been enlarged by the erection of new buildings and alterations made in the old one; it has now 104 beds, with air space of 1430 cubic feet for each. The income for the year nearly balanced the expenditure.

SICK CHILDREN'S HOSPITAL.

During 1886 the cases admitted to this hospital numbered 458, the highest total since the hospital was opened four years ago. None of the wards had been closed on account of infectious disease during the year. The mortality, after deducting deaths within twenty-four hours of admission, was 6·8 per cent. The directors intend very shortly to proceed to the erection of a dispensary. The income for 1886 fell short of the sum expended by £140.

THE LUNACY LAWS.

A somewhat unusual case was before Sheriff Rutherfurd of Edinburgh a few days ago, a gentleman who had been detained in Morningside Asylum on the certificates of Drs. Littlejohn and Clouston having lodged a *caveat* to stay proceedings. After the case had been certified, the Sheriff said he thought it was certainly a matter of great regret that the Legislature had devolved upon a single judge, sitting alone, whose judgment was by statute to be final and conclusive, without the intervention of a jury, to state what the mental condition of a party was. The question before him now was the present state of mind of the gentleman in question and whether he was in such a state as to threaten danger to himself or others. The judge did not think it was a bad case, but as a man of common sense, and one accustomed to weigh evidence, he could come to no other conclusion than that the unfortunate gentleman was at present in a state of unsound mind, and that while these delusions continued, he might at any moment become excited and dangerous to himself or

Digitized by Google

others. He (the Sheriff) must, therefore, act upon that, and grant the prayer of the petition. The patient was accordingly conveyed back to Morningside Asylum, it being understood that he might at any time obtain the intervention of the Inspectors of Lunacy to inquire as to his state of mind.

DUBLIN.

(From our own Correspondent.)

SIMPSON'S HOSPITAL.

BY the death of Dr. Henry Kennedy, a vacancy for a physician to this institution has arisen, and it will probably be filled up by the trustees at their quarterly meeting this month. For the appointment, the emoluments of which are £25 per annum, Drs. C. H. Robinson, J. W. Moore, and H. C. Tweedy are candidates.

BRITISH MEDICAL ASSOCIATION (DUBLIN BRANCH).

At the annual meeting of the Branch held last week, the inaugural address was delivered by Dr. Grimshaw, Registrar-General for Ireland. In the course of his address, he said that we had high political authority for stating that the health of the people should be the first care of a government, and if this was so, and if *sanitas sanitatum omnia sanitas* was ever to become a reality, and not merely the motto for the professors of a "policy of sewage," it was manifest that their profession must take a highly important position in the fabric of the State. Did their profession occupy such a position? He was afraid the answer must be that it did not, either in this or in any other country that he was aware of. Many of those who had not given sufficient attention to the question thought that these faults in their profession were owing to defects inherent in the profession itself. This was by no means the case. The fault mainly lay with the State. The medical profession had two principal relations to the public—viz., those comprised under the heads of the prevention of disease and the cure of disease. While the duties under the former head have to be mainly performed towards the public in its collective capacity, those under the latter have to be mainly rendered by individual members of the profession to individual members of the public. While the relative scope of preventive and of curative medicine might thus be respectively defined in general terms, it was clear that preventive medicine must often be practised individually—as, for instance, when they advised as to family hygiene and healthy homes. Curative medicine might also be practised collectively where the Poor-law medical officer or the medical officer of a hospital or public institution treats large numbers of sick on an organised system of medical attendance. When viewed from a State standpoint, this crossing of the functions of the profession in its private and public capacities presented difficulties which must necessarily complicate the relations between the State and the profession. These difficulties were not insurmountable, though their existence must be admitted by all persons, and, indeed, a considerable number of them had been surmounted slowly and by a sort of quiet progressive development through the public medical system of Ireland. The annual dinner of the Branch took place in the evening, at the College of Physicians.

MERCER'S HOSPITAL.

At the Southern Divisional Police-court, Dublin, last week, Dr. Kennedy, resident surgeon to Mercer's Hospital, was charged by Mrs. Farrell with having accelerated the death of her husband, Joseph Farrell, by assaulting him while a patient in that hospital in August last. Evidence of a most contradictory kind was given, and after several adjournments it was ultimately decided to have the matter settled before a jury. Dr. Kennedy has therefore been returned for trial at the Quarter Sessions, which will be held this month, his own security in £100 being taken for his appearance.

Dr. Swan, of Monaghan, has been elected medical officer to Monaghan dispensary district, in the vacancy caused by the decease of Dr. William Woods.

There will be a fancy and full-dress ball on the 9th inst., in aid of the funds of St. Michael's Hospital, Kingstown.

Dublin, Feb. 1st.

BELFAST.

(From our own Correspondent.)

BELFAST HOSPITAL FOR SICK CHILDREN.

FROM the medical report presented at the annual meeting of this charity (Mr. Dunville, D.L., High Sheriff of co. Down, in the chair) I learn that there were 829 in-patients and 8694 out-patients during the year 1886. During the present session there are the usual cliniques, which are attended by the senior students of the medical school. In accordance with one of the rules, a meeting was held on Jan. 19th, when Dr. M'Caw, one of the physicians, was re-elected for a period of four years. A letter was read from the Hon. R. J. O'Neill, M.P., the president of the hospital, urging strongly the claims of the Convalescent Fund, by which children are sent to the country and seaside for change of air after having been in the hospital. The financial statement showed that the income was slightly in excess of the expenditure.

ULSTER EYE, EAR, AND THROAT HOSPITAL.

At the annual meeting of this hospital it was reported that during the past year 1789 patients had attended, and of these 180 were intern. The total receipts for the past year were £550 6*s.* 5*d.*, and the expenditure £541 14*s.* Dr. W. A. McKeown (honorary surgeon of the hospital) mentioned in his report that upwards of 500 cataract operations had been performed since the opening of the hospital, the patients being from all parts of the province. He alluded to the absurd superstitions that still exist in regard to diseases of the eye, and said that every year a number of eyes were lost through ignorance and so called "popular remedies." Dr. McKeown referred with just satisfaction to the fact that it was in this hospital first that the magnet was employed to remove pieces of metal from the eye in 1873. Three years afterwards the practice was adopted by Prof. Hirschberg (Berlin), and now it is a settled practice all over the world. In May, 1884, Dr. McKeown originated his new operation for cataract, by which patients are prevented waiting, as it matters little whether a cataract is "ripe" or not for this method to be used. This institution is becoming more and more self-supporting, as for the last five years the contributions of patients (£2070 2*s.* 6*d.*) are in excess of those for the previous eleven years by £238 11*s.* 8*d.*

SAMARITAN HOSPITAL.

The report read at the annual meeting of this hospital showed that there were 148 intern and 974 extern patients during the year. The committee expressed the hope that some benevolent person will see his way to build a wing to the present building suitable for a lying-in department.

BELFAST MAIN-DRAINAGE SCHEME.

A report has been prepared by the Lagan Pollution Committee in which they point out what they deem defective in the drainage scheme of our Town Council. They object that as to the high-level main sewer proposed to be constructed no special system of ventilation is provided, and they believe the ordinary street ventilation gratings would constantly be giving off poisonous gases. Further, the fall in this sewer (1 inch in 120 feet) is so slight that the committee allege it will become a sewer of deposit. Again, no provision is made by this scheme to drain the Falls district, one of the most densely populated parts of the town, and all the sewage of this must continue to find its way into the Lagan. After stating other objections, the committee say they urged upon the Town Council the adoption of the scheme proposed by a gentleman named Gilliland. Such a scheme could be carried out for £18,000. It is not an alternative but a necessary adjunct to the main-drainage scheme, and as absolutely necessary to secure the purification of the Lagan. The works, the committee think, could be carried out simultaneously with the erection of the new Albert Bridge, and would entirely abate the Lagan nuisance, and convert the river above this bridge into a highly ornamental sheet of water. In conclusion, the committee think that the main-drainage scheme would entail an enormous expenditure without any corresponding advantage. At some of the recent meetings of the Ulster Medical Society papers were read on the proposed drainage schemes, and a very interesting discussion took place. There can be no doubt that Belfast, from its peculiar situation and from the great rapidity of its growth, is a town for which it is extremely difficult to construct a

Digitized by Google

thorough system of drainage, but it is to be hoped the problem in time will be solved to the satisfaction of all parties.

BELFAST ROYAL HOSPITAL.

I am glad to say that the treasurer has received over £1000 in aid of a special fund to pay off the debt incurred during the year ending Aug. 31st, 1886.

Belfast, Feb. 1st.

PARIS.

(From our own Correspondent.)

SANITARY STATISTICS.

THE last number of the *Bulletin Hebdomadaire de Statistique Municipale* gives a retrospect of the sanitary condition of Paris during the past year, from which it appears that the principal epidemic diseases have been less frequent. Typhoid fever has caused 1009 deaths, or 45 per 100,000 inhabitants, which is one of the lowest percentages of the last twenty-five years. In 1885 there were 59 deaths per 100,000 of the population. The deaths for the first and second quarters of 1886 numbered 212 and 171 respectively. In August the mortality increased to 148 for the month. Since then it has diminished, although it remains higher than during the first half of the year. Small-pox, as usual, capricious in its evolutions, has caused in all 213 deaths, or 9 per 100,000 inhabitants, being 97, 73, 24, and 19 for the respective quarters. Measles shows a tendency to increase in frequency year by year, but the mortality for 1886 is less than that of the preceding two periods. From 1865 to 1869 the average was 32 deaths per 100,000 inhabitants. From 1872 to 1876 it was 35; from 1877 to 1881, 39. In 1880 it was 44 per 100,000 of the population; in 1883, 49; in 1884, 67; and in 1885, 68. During the year 1886 there have been 1238 deaths, giving a mortality of 55 per 100,000. Scarlatina has been three times as fatal as in 1882 and 1883, when there were 6 deaths per 100,000 of the population; twice as fatal as in 1885, when the death-rate for the same number of people was nine. In 1886 there were altogether 410 deaths, being 18 per 100,000 inhabitants, the maximum (67) being in June. Diphtheria has increased in frequency in Paris, during the last twenty years in the same way as measles. For 100,000 inhabitants the mortality from 1865 to 1869 was 43 deaths. From 1877 to 1883 it increased progressively to nearly 100. In 1884 it was 93; in 1885, 79; in 1886 there were altogether 1628 deaths, representing 72 per 100,000 of the population.

TYPHOID POSSIBILITIES.

In connexion with the above statistics, it must be remarked that if the health of Paris has appeared more satisfactory during the past twelve months, the improvement is due to providential causes rather than to any attention on the part of the authorities to sanitary matters. All Parisian residents are more or less protected against typhoid by acclimatisation in an attenuated typhoid atmosphere, and the chief victims to the disease are generally visitors or new-comers. When, on account of some unusual influx of strangers, or for some less evident atmospheric or telluric reason, the typhoid nisus increases in virulence and the "directing classes" suffer, there is always a talk of sanitary improvements, which are forgotten as soon as the alarm is over. In respect to typhoid, the health of Paris has probably benefited by the general commercial stagnation, which has made the past year a bad one for hotel-keepers. The mortality has been no doubt restricted in a great measure by the absence of the potential victims. The laws of supply and demand must also hold good in bacteriology, and the poorer classes, having been more or less decimated in previous years, have necessarily contained a smaller number of individuals in a state of receptivity. To predict the sanitary possibilities for the coming year would be somewhat hazardous, but there are immediate indications of epidemic and portents, if not in the air, in the water, not without their meaning. Paris is supplied with drinking water from the Vanne, the Dhuys, the Seine, and the Ourcq. That of the first two is of good quality, whereas the water of the Seine and the Ourcq, to quote the opinion of M. Léon Collin, is "hot in the summer, cold in the winter, disturbed and muddy at all times, and contaminated by waste product and human excreta." At the present moment the supply from the Vanne is temporarily suppressed on account of repairs to the aqueduct which conveys it to Paris, and the districts in which it is usually supplied are now furnished with typhogenic water from the Seine. It is a matter of general observation that enteric fever has been on the increase during the last few weeks, the mortality from this cause having been higher last week than during the preceding one. The distribution of bad water to those unaccustomed to it is not likely to check the morbidity; and visitors to Paris, to whom the risk is greatest, will do well to adopt simple precautions against infection. Boiled filtered water is not easily procurable in hotels, and the best plan is perhaps, to use genuine mineral waters. The familiar syphon is not to be trusted, being often filled from an impure source.

THE TREATMENT OF TYPHOID.

Professor Grancher, following in the steps of Professor Bouchard, gives the following directions for the treatment of enterica: Four principal indications result from the pathogeny of the disease—general antisepsis, intestinal antisepsis, antipyretics, and nourishment. As soon as the disease is suspected, M. Bouchard commences by the administration of a purgative which is renewed every three days. For the first four days, calomel is given in doses of one-third of a grain every hour as a general antiseptic. Intestinal antisepsis is secured by the administration of vegetable charcoal in powder (100 grammes), iodoform (1 gramme), and naphthaline (5 grammes). This is mixed with 50 grammes of peptone and 200 grammes of glycerine, which constitute the basis of the alimentation, and the black magma so formed is taken by table spoonfuls every two hours. The bowels are washed out night and morning with carbolic acid and water (1 in 1000) each enema measuring one pint. From the beginning of the disease the patient takes eight baths a day until recovery, but instead of using water at a much lower temperature than that of the body, the difference is only of two degrees Centigrade, 38°, for instance, of the temperature is 40°. The bath is then cooled by a tenth of a degree per minute to 30°, but never below, so avoiding all shock and spasm. When the temperature remains high, notwithstanding the baths, quinine is recommended, 30 grains being given in four doses, in the course of two hours, and repeated after an interval of three days. Besides the glycerine and peptone associated with the antiseptics the only other food allowed is bouillon, boiled with barley and as a drink lemonade with a little wine. Should complications occur, they should also meet with a vigorous reception. Extreme or prolonged delirium is to be treated by opium, and peritonitic symptoms by ice or mercurial ointment. Of 266 patients so treated by M. Bouchard 31 died, giving a mortality of 11·7 per cent. The average duration of the disease was nineteen days, and relapses took place on the whole number in 20 per cent., and during the latter period in 10 per cent. of the cases. These figures speak for themselves, and there is one point about M. Bouchard's method beyond contestation. It is certainly thorough. But if, as it would seem, the patient spends thirteen hours in the bath and undergoes fifty or sixty other visitations of different kinds in the course of the twenty-four hours, it is difficult to see what time remains for repose.

PASTEURIANA.

The *Temps* of Tuesday evening gives the following particulars of another death after the preventive treatment:—M. Bergé, living at Bordeaux, was bitten five or six months ago by a mad dog, and went to Paris, where he was submitted to M. Pasteur's treatment. On his return to Bordeaux he appeared to be quite cured, but two days ago symptoms of rabies set in, and it became necessary to send the patient to the St. André Hospital, where he died yesterday. The post-mortem examination was made this morning by M. Peter, dean of the Faculty of Medicine, who declined to give any opinion, but who has made with the medulla inoculations on rabbits. The results of these inoculations will show whether M. Bergé did or did not die of rabies. M. Peter, in a recent clinical lecture, stated that a child had died of rabies at Sceaux after the intensive treatment. *Per contra*, at the Academy of Sciences, the statistical account, published in your last issue, was received with enthusiasm, and it was decided, on the proposition of M. Bertrand, that a reprint of M. Vulpian's note should

Digitized by Google

be made by authority of the Academy *(sous l'estampille de la compagnie)*, and distributed to all the French and foreign committees now collecting subscriptions for the Pasteur Institute. This has already been done, and the note forms a small pamphlet in quarto, with the seal of the Academy engraved on the title page—a broad hint to future candidates for the honour of membership. At the Academy of Medicine a note was read from M. Cantini, of Naples, giving details of his experience of the method, which are entirely favourable, none of the patients having as yet died. At the Société de Biologie, M. Gameleva related sixteen cases of rabies in which paralytic symptoms had occurred, although no preventive inoculations had been performed, thus showing that the paralytic form of the disease is not necessarily *canino-experimental*. A similar case was mentioned by M. Laborde.

THE LATE DR. GALLARD.

The death is announced of Dr. Gallard, physician to the Paris hospitals and member of the Academy of Medicine. Dr. Gallard was a practitioner of great merit, and although not officially connected with the School of Medicine, he was the teacher of gynæcology, whose wards were the most frequented by students. His loss will be the more felt in this respect in that there is no chair of women's diseases at the Faculty. Dr. Gallard was also senior physician to the Orleans Railway, and in this capacity rendered great services in medical organisation during the siege, for which he was made an officer of the Legion of Honour. The death is also announced of another gynæcologist, Dr. Nonat, who, having far exceeded the usual span of life, had dropped in a certain measure out of the memory of the present generation. Middle-aged men still remember him at the Charité, where his practice chiefly consisted in leeching the uterus. Nonat was a nephew of the great chemist, Thénard.

A NEW DENTIFRICE.

The *Gazette Hebdomadaire* contains an article by M. Paul Vigier on the Use of Steatite as a Tooth Powder. Many years back M. Vigier discovered that the addition of powdered talc to water prevented the deposit of calcareous salts in boilers. Applying this fact to dental therapeutics, M. Vigier has devised a new dentifrice, which, he says, prevents the formation of tartar. The formula is as follows:—Powdered steatite, 60 grammes; desiccated alum or cream of tartar, 5 grammes; powdered cochineal, 10 grammes; essence of peppermint, 20 drops. Any other perfume may of course be substituted.

Obituary.

HENRY KENNEDY, M.B., M.R.I.A.

WITH regret we record the death of a well-known Dublin physician, who died on Jan. 24th at his residence in Rutland-square. Although in his seventy-sixth year, Dr. Kennedy was of very active habits, and was possessed of a wonderful amount of vitality considering his advanced age. He obtained his degree in Arts and Medicine at the University of Dublin in 1839, and was elected a Fellow of the College of Physicians ten years afterwards. Connected for some years as visiting physician to Cork-street Fever Hospital, he made great use of the valuable material at his command; and a good deal of the experience in fever and diseases of children, for which he was so justly celebrated, was obtained at this institution. He was also physician to Simpson's and the Whitworth Hospitals. The deceased was a constant attendant at the various medical societies, and proved himself an apt and fluent speaker in the discussions which ensued on the various papers read before the members. He was a prolific writer, the following being only a few of the numerous papers he contributed to medical literature:—"Essay on Fatty Heart," "On Slow Pulse in Fever," "On Scarlatina," "On some of the Forms of Paralysis which occur in Early Life," "On the Coexistence of Functional and Organic Disease of the Kidney," "On Hydrocephalus and its Treatment," &c.

RICHARD FORTH SNAPE, F.R.C.S. ENG.

WE regret to record the death of Mr. Richard Forth Snape, which occurred at his residence, Chorley New-road, Bolton, on January 13th. Mr. Snape took up his abode in the town about forty years ago, and some years afterwards became for a time one of the honorary surgeons to the infirmary and dispensary. He early took an interest in the question of the health and long hours of employment of children and young persons in cotton mills, and was instrumental, along with several other gentlemen, in promoting a demonstration of the inhabitants of the town in favour of petitioning the Legislature to pass an efficient Bill for shortening the hours of labour in factories. At the meeting at which this resolution was adopted, and which was held on Jan. 25th, 1847, Lord Ashley (afterwards Earl of Shaftesbury) was present. Mr. Snape had for many years up to his decease held the post of certifying factory surgeon. He was a staunch Conservative and an ardent member of the Church of England, but abstained from any active share in public affairs, his professional duties requiring most of his time and attention, being consulted by many of the influential families in the town and neighbourhood. As a practitioner he was judicious and philosophical in his views, ever cautious to keep himself informed of the most recent discoveries. Few men have possessed to so marked an extent as he did the instincts of a doctor, or have loved their profession more; his kindliness of heart and unaffected simplicity of character had won for him the love and esteem of a large circle of friends, many of whom will continue to think of him with affection and tender regret. He leaves a widow and three sons.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The list of new Members was given in our last issue, page 244.

The following were admitted Licentiates on Jan. 27th:—

Andrews, Archibald George, Poplar Hospital, East India-road.
Ballance, John Des Carrières, Harley-street.
Barlow, Charles, Aspinall-street, Prescot.
Barr, George Arthur, Newport, Isle of Wight.
Barton, Edwin Alfred, University Hospital.
Belson, George de Veulle, Albion-street, Hyde-park.
Blenkinsop, Alfred Percy, Hilldrop-crescent, Holloway.
Bostock, Robert Ashton, South Camp, Aldershot.
Boxall, Frank, Oakley-square.
Bradbury, Harvey Kimmersley, Hill's-place, Regent-circus.
Brodie, Frederick Carden, Middlesex Hospital.
Browne, Edward Granville, Bernard-street, Russell-square.
Bulstrode, Herbert Timbrell, St. Thomas's Hospital.
Butler, Henry John, New Wortley, Leeds.
Calthrop, Lionel Claude, Cheal, Hornsey-lane.
Calvert, John Telfer, Osborne-terrace, Clapham-road.
Calvert, William Dobree, Sewardstone-road, Victoria-park.
Clark, Brown, London Hospital.
Connolly, Frank Glynn, London Hospital.
Cosens, William Burrough, Philpot-street, Mile-end.
Cox, Alfred Harold Lissant, Millman-street, Bedford-row.
Crook, Herbert Evelyn, Northfleet.
Cross, Robert George, Compton-terrace, Highbury.
Dalgleish, John William, West-parade, Newcastle-on-Tyne.
Debenham, Horace Allan, Stepney.
Downing, William, Varna-road, Birmingham.
Downman, Charles Frederick, Newmarket.
Drinkwater, Charles, King's College Hospital.
Duncan, Horace, Henrietta-street, Covent-garden.
Duncker, William Reinhold, Finsbury-park-road.
Edye, John Simpson, Army Medical Staff, Colchester.
Evelyn, William Arthur, Vincent-square, Westminster.
FitzGerald, Gerald Eustace, Shrewsbury-road, Westbourne-park.
Fraser, Paul Wilkes, Gainsford-street, Kentish-town.
Furnivall, Bryan, St. Bartholomew's Hospital.
Garrould, Walter Robert, Willesden-park.
Hall, Herbert Strange, Bradshawgate, Leigh, Lancashire.
Haslip, George Ernest, Whitehall-place, Gravesend.
Helsham, Hugh Paul, Charlwood-street, Pimlico.
Holloway, Samuel Frederick, Osman-road.
Husbands, Harold Wessen, Wellington-park, Clifton, Bristol.
Iredale, Thomas, Midland-road, Headingley, Leeds.
Jarvis, William Charles, Southampton-street, Camberwell.
Jeaffreson, John Leslie, Park-crescent, Stoke Newington.
Johnson, John George, Lansdowne-road, Clapham.
Joly, Joseph Antoine Maurice, Oppidans-road, Primrose-hill.
Jones, John Owen, Cambridge-terrace, Islington.
Kitson, Francis Parsons, Maitland-park-villas, Haverstock-hill.
Knaggs, Francis Henry, Disraeli-road, Putney.
Lansdale, William, Chelsham-road, Clapham.
Loxton, William Arthur, Bath-row, Birmingham.
McKague, William Henry, Burton-crescent.
McShane, George, Shaftesbury-road, Southsea.
Mann, Harold Edward, West Cromwell-road, Kensington.
Martin, Frederick George Sturridge Goodall, Haverstock-hill.
Maxwell, Matthew, Hunter-street, Brunswick-square.
Miller, Frederick Richard, Frederick-street, Gray's-inn-road.
Moore, James, Gotha-street, Victoria-park-road.
Morgan, George Frederic Elliot, Southwark-bridge-road.
Morgan, William Vaughan, Glen Marteg, Streatham-park.
Mould, William Thomas, Fairholme-road, Kensington.
Moxham, Marcus Camplin, Crescent-street, Thornhill-square.
Nihill, John Edward, Newcastle-on-Tyne.
Ord, George William, Streatham-hill.

Digitized by Google

Pedley, George Aston, Terrace, Camberwell.
Peeke, Harold Samuel, Sinclair-road, Kensington.
Pepler, William Herbert, Redburn-street, Chelsea.
Pinniger, Charles Lever, Blessington-road, Lee.
Powell, Edgar Elkins, Stoke-road, Guildford.
Quiller, Charles Turner, Orlando-road, Clapham.
Roalfe-Cox, Walter John, Hermitage, Streatham.
Rosenau, Albert, Bath, Kissingen, Germany.
Sharman, John Schütze William Edward, Oak Villas, Norwood.
Stott, Hugh, Carlton Villas, Colney Hatch.
Strickland, Percy Charles Hutchison, Montague-street, Russell-square.
Thane, Elgar Herbert, Montague-street, Russell-square.
Thompson, Stephen Robert, Glenmore House, Dulwich.
Trow, Charles, Endsleigh-street, Tavistock-square.
Tweed, Edward Reginald, Upper Brook-street, Grosvenor-square.
Vidler, Albert Edward, Clapton-square.
Wale, George, West Kent Hospital, Maidstone.
Walker, Alfred William Hinsley, Hampden Club, St. Pancras.
Wheeler, Humphry John, Abingdon Villas, Kensington.
Wilbe, Richard Haydock Wiffin, Finchley-road.
Wilson, William, Hollies, Cleveland-road, Wanstead.
Wreford, John, Clapham-road.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on Jan. 25th:

Belson, George de Veulle, L.R.C.P. Lond., Albion-street.
Brodie, Frederick Carden, L.S.A., Wootton Bridge, Isle of Wight.
Calvert, John Telfer, L.R.C.P. Lond., King's-road, Rochdale.
Calvert, W. Dobree, L.R.C.P. Lond., East Bergholt, Colchester.
Holloway, Samuel F., L.R.C.P. Lond., West Kensington-park.
Joly, Antoine Maurice, L.R.C.P. Lond., Oppidans-road.
Jones, John Arnallt, L.R.C.P. Lond., Fort Talbot, Glamorgan.
Key, David Thomas, L.S.A., Trinity-square, Borough.
Mann, Harold Edward, L.R.C.P. Lond., West Cromwell-road, Kensington.
Parry, Thomas Fox, L.K.Q.C.P.I., Ling-street, Liverpool.
Sidebottom, Ralph Bennett, L.R.C.P. Lond., Manor House, Mottram.
Slater, William Arnison, L.S.A., Green-lane.
Vidler, Albert Edward, L.S.A., Magdale House, Rye, Sussex.
Wheeler, Humphry John, L.R.C.P. Lond., Abingdon Villas.

Admitted on the 26th ult.:—

Barr, George Arthur, L.R.C.P. Lond., Milner-street.
Barton, Edwin Alfred, L.R.C.P. Lond., Lexham-gardens.
Bindley, Robert Alfred, Highbury-hill.
Carvalho, Alberto Pedro de, L.S.A., Lidlington-place, Ampthill-square.
Copeman, Sydney Arthur Monckton, M.B. Cantab., York-road.
Debenham, Horace Allan, L.R.C.P. Lond., Heath House, Stepney.
Haslip, George E., L.R.C.P. Lond., Whitehall-place, Gravesend.
Husbands, Harold Wessens, L.R.C.P. Lond., Wellington-park, Clifton.
Jarvis, William Charles, L.S.A., Southampton-street.
Jeaffreson, John Leslie, L.R.C.P. Lond., Park-crescent, Stoke Newington.
Lyle, Charles Conway Vacey, L.R.C.P. Lond., Maryland-road.
Malpas, James, L.R.C.P. Lond., H.M. Dockyard, Pembroke.
Martin, Frederick George Sturridge Goodall, L.R.C.P. Lond., Haverstock-hill.
Morgan, William Vaughan, L.R.C.P. Lond., Streatham-park.
Norton, Henry Harvey, Beddenden, Kent.
Smith, Percival, L.S.A., Harley-street.

Admitted on the 27th ult.:—

Carey, Basil de Beauvoir, L.S.A., Guernsey.
Cosens, Wm. Burrough, L.R.C.P. Lond., The Vicarage, Dudley.
Cox, W. J. Roalfe, L.R.C.P. Lond., The Hermitage, Streatham.
Davey, Thomas George, L.S.A., Helsham, Cornwall.
England, George Fuller Ashbridge, L.S.A., Winchester, Hants.
Gilpin, William John, L.S.A., The Grove, Bedford.
Going, Joseph Audrew, L.S.A., Wanstead.
Hawkins, Herbert Pennell, L.S.A., Vincent-square, Westminster.
Iredale, Thomas, L.R.C.P. Lond., Leeds.
Lewis, John Nicholls, L.S.A., Primrose Cottage, Swansea.
Macnab, Allan James, L.R.C.P. Lond., Philbeach-gardens.
Oldham, Montague Williams, L.S.A., Southam, Warwickshire.
Ord, George William, L.R.C.P. Lond., Streatham-hill.
Phillips, Thomas, L.S.A., Newcastle Emlyn South Wales.
Pridham, William Frederick, L.S.A., Cromwell-crescent.
Quiller, Chas. Turner, L.R.C.P. Lond., Orlando-road, Clapham-common.
Rusher, John Golby, L.S.A., Finsbury-park.
Sansom, Harry Arthur, L.R.C.P. Lond., Harley-street.
Sen, Chandi Charan, L.R.C.P. Lond., Hanwell.
Walker, Alfred William Hensley, L.R.C.P. Lond., Hampden Club.
Wilson, A. Harvey, M.D. Dartmouth, South Boston, Mass., U.S.A.
Wreford, John, L.R.C.P. Lond., Clapham-road.

Admitted on the 28th ult.:—

Hill, Charles Marshall, L.R.C.P. Lond., Halifax.
Oliver, Charles Pye, L.S.A., Maidstone.
Ormerod, Edward Booth, L.S.A., Robe Town, South Australia.
Peeke, Harold Samuel, L.R.C.P. Lond., Kensington.
Powell, Elgar Elkins, L.R.C.P. Lond., Guildford.
Wilde, Leonard, L.S.A., Watford.

COLLEGE LECTURES.—Professor Francis Warner, M.D., F.R.C.S., will deliver a course of three lectures on "The Anatomy of Movement." The lectures will be delivered on Monday, Wednesday, and Friday, the 7th, 9th, and 11th inst., at 4 o'clock precisely each day.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 27th ult, the degree of M.B. was conferred on the following gentlemen:—

George Gavin Morrice, Trinity; William Percival Gore Graham, Gonville and Caius.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on the 27th ult.:—

Gilpin, William John, The Grove, Bedford.
Hawkins, Herbert Pennell, Vincent-square, Westminster.
Lewis, John Nicholls, Granby-street, Hampstead-road.
Ormerod, Edward Booth, Lawn-terrace, Blackheath.
Prowse, John Skardon, Earl-street, Cambridge.

THE Hospital Sunday collection was held at Rotherham on the 30th ult.

THE eighth annual dinner of the Leeds medical students (past and present) was held on the 28th ult.

THE recent Hospital Sunday Collection at Reading realised £237.

THE Queen has been pleased to sanction the Hull Children's Hospital being called in future "The Victoria Hospital for Sick Children, Hull."

THE seventy-first annual general meeting of the supporters of the Weymouth Royal Hospital was held on the 20th inst.

THE financial report of the Tiverton Infirmary and Dispensary, which was read at the annual meeting on the 26th ult, was unsatisfactory.

AT the annual meeting of the governors of and subscribers to the Hertford General Infirmary, on the 20th ult., an unsatisfactory financial report was presented. The deficit amounted to £1118.

BILLS to amend and consolidate the Acts relating to lunatics have been laid on the table of the House of Peers by the Lord Chancellor, who proposes to move the second reading of the measures on Monday next.

AT a large meeting of the inhabitants of Dartmouth on the 18th ult., it was decided to erect a cottage hospital, with a dispensary, for the town and surrounding district, in celebration of the Jubilee.

RABIES.—An Order in Council, entitled "The Rabies Order of 1887," has been officially published. It lays down certain fresh regulations in regard to animals found to be affected with rabies, more especially dogs. The order, which will take effect from and after the 28th inst., will not interfere with the operation of the Dogs Act, 1871.

ROYAL MATERNITY CHARITY.—The annual meeting of the governors of this charity was held on the 25th ult., Sir John Lubbock, M.P., presiding. The report of the managing committee, which was read, showed that 4000 poor married women had been administered to during the past year. The expenditure amounted to £3371, and the income to £3740.

SHEFFIELD HOSPITAL SUNDAY COLLECTION.—A total of £2278 has already been received as the result of the appeals made in the churches and chapels of Sheffield on the 30th ult., in aid of the local medical charities. This is an increase of £156 over the amount received last year, and there are several sums yet to come in, which it is estimated will bring the total amount received this year to about £2300.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—At the next quarterly meeting to be held at Bethlem Hospital, St. George's-road, on Feb. 23rd, it is proposed to discuss the question "Whether there is ever sufficient reason for the use of strong clothing and side-arm dresses." Dr. Percy Smith will read a communication on "The results of an Epidemic of Typhoid Fever in the Insane."

LONDON HOSPITAL SATURDAY FUND.—Seventy-five metropolitan hospitals and fifty-seven dispensaries have participated in the awards of the above fund. The following are among the chief items:—Charing-cross, £162; King's College, £175; London, £586; Middlesex, £276; St. George's £267; St. Mary's, £224; University College, £204; Westminster, £208; Royal Free, 168; Seamen's, £111; West London, £131; Brompton Consumption, £589; North London, £176; Victoria-park, £288; Royal National, £108; Ormond-street Children's, £120; Temperance, £73; City-road, £96; Cancer, £115; German, £115.

Digitized by Google

THE annual collections in aid of the local medical charities were held in Nottingham on the 29th and 30th ult.

THE fifty-fourth annual meeting of the subscribers to the Sussex Eye Hospital was held at Brighton on the 27th ult. The receipts exceeded those of previous years, but additional subscriptions were appealed for, the numbers of patients being year by year on the increase.

WINDSOR ROYAL DISPENSARY AND INFIRMARY.—The report which was read on the 27th ult. at the annual meeting of the supporters of this institution showed that during 1886 the total revenue amounted to £1939 and the expenditure to £2036. The number of in-patients was 269, as against 176 in 1885, and of out-patients 3661, as against 4123.

THE annual general meeting of the National Association for Supplying Female Medical Aid to the Women of India was held on the 26th ult., under the presidency of the Viceroy, who congratulated the Association upon the firm hold it had obtained upon the affections and conviction of the people of India. The funds amount to over three and a half lakhs of rupees, but an appeal was made for further assistance.

SANITARY REGISTRATION OF BUILDINGS BILL.—A special meeting of the Council of the Sanitary Assurance Association was held on Monday last, for the final revision of the above Bill before presentation to the House of Commons, Sir Joseph Fayrer, K.C.S.I., F.R.S., in the chair. The new measure was adopted by the Council, and in the absence of Dr. Farquharson, M.P., from England, it was decided to ask Mr. C. C. Lacaita, M.P., to take charge of the Bill in the House of Commons.

IN his annual report to the Commissioners of Sewers of the City of London, Dr. Saunders reports that during 1886 he has analysed 61 samples of milk, 22 of whisky, 9 of gin, 16 of mustard, 27 of drugs, 10 of disinfectants, 6 of water, 4 of butter and butterine, 2 of pepper, 2 of mineral waters, 2 of oil, 6 of pickles, 12 of preserved herrings, 3 of bread, and 6 of arrowroot. Dr. Saunders states that the apathy of the public in the working of the Food and Drugs Acts, which he has previously commented on, still continues.

DORSET COUNTY HOSPITAL.—The annual meeting of the subscribers to this institution was held on the 27th ult., when the report, which was read and adopted, showed that the total receipts were £2454, and the expenditure £2387. Charges of extravagance in the salaries of the paid staff, and in the amount spent on surgical instruments and lint, were made by several subscribers; and it was eventually resolved that all future reports should be published at least one week before the meeting, in order that the various items may be carefully considered before their adoption by the subscribers.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADAMS, JAMES, M.D.Aber., M.R.C.S., has been re-elected Surgeon to the Ashburton and Buckfastleigh Cottage Hospital.

BARRON, HUNTER, M.B., C.M., M.R.C.S., L.R.C.P., has been appointed Medical Officer to Christ's College, Finchley, N., vice W. Phelps, M.R.C.S., resigned; also Medical Officer to the Convent of the Good Shepherd, Finchley, N., vice W. Phelps, M.R.C.S., resigned.

BICKERTON, T. H., L.R.C.P.Ed., M.R.C.S., has been appointed Oculist to the Liverpool Royal Infirmary.

BOYS, A. H., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Second District of the St. Alban's Union.

CESAR, J., L.R.C.P.Ed., L.R.C.S., has been appointed by the Home Office Certifying Factory Surgeon for Elmly, Sheppey.

HUTCHINSON, A. C., M.B., C.M. Aber., has been appointed Honorary Medical Officer to the Brighton, Hove, and Preston Dispensary.

KEMBLE, ARTHUR C., L.R.C.P., L.R.C.S., L.M.Ed., has been appointed Surgeon to the Roman Gravels and Wotherton Lead Mines; also Medical Officer and Public Vaccinator to the Worthen District of the Forden Union, Shropshire, vice T. L. Macartney, L.R.C.P., L.R.C.S., L.M.Edin., resigned.

POLLARD, CHARLES, M.R.C.S., L.R.C.P., has been appointed Assistant Medical Officer to the St. George's Union Infirmary, Fulham-road.

PRITCHETT, HENRY, M.R.C.S., L.S.A., has been appointed Medical Officer for the Workhouse and the Second District of the Bedminster Union.

ROBERTS, JAS. BLACK, M.B., C.M.Edin., has been appointed Medical Examiner to the Nottingham School Board.

STARK, ARTHUR C., M.B., C.M.Ed., has been appointed Medical Officer for the Third District of the Romsey Union.

STEPHENSON, WILLIAM, M.R.C.S., L.S.A., has been appointed Honorary Surgeon to the Beverley Cottage Hospital.

STUART, CHAS., M.B., C.M.Ed., has been appointed Medical Officer for the Great Ayton District of the Stokesley Union.

UBSDELL, HENRY, M.R.C.S., L.S.A., has been re-elected Surgeon to the Ashburton and Buckfastleigh Cottage Hospital.

VOGAN, JAMES N., L.R.C.P. Lond., F.R.C.S.E., has been appointed Medical Officer for the St. Matthew's District of the Ipswich Union.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

DONCASTER GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board and residence in the house.

ROYAL ALBERT HOSPITAL, Devonport.—Honorary Surgeon.

TUNBRIDGE WELLS GENERAL HOSPITAL.—House-Surgeon and Secretary. Salary £100 per annum, together with board, furnished apartments in the hospital, gas, firing, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

BELL.—On Dec. 30th, at Meean Meer, Punjab, the wife of Surgeon W. Howard Bell, Medical Staff, of a daughter.

JOBSON.—On the 26th ult., at Keillour House, Perthshire, the wife of Brigade-Surgeon Jobson, M.D., of a son.

MURPHY.—On the 26th ult., the wife of Harry A. Murphy, L.R.C.S., L.R.C.P.Ed., of Bolton, Lancashire, of a daughter.

SYRÉE.—On the 23rd ult., the wife of Anton Hugh Syrée, M.R.C.S., of Northallerton, Yorkshire, of a son.

TAUNTON.—On the 25th ult., at West Norwood, S.E., the wife of W. M. Taunton, M.R.C.P.Ed., M.R.C.S., of a daughter.

WOOLDRIDGE.—On the 29th ult., at Priory-villas, Barnes, S.W., the wife of Leonard C. Wooldridge, M.D., D.Sc., of a daughter.

MARRIAGES.

BRANFOOT—CARTER.—On Dec. 18th, at St. George's Cathedral, Madras, Arthur Mudge Branfoot, Surgeon-Major, I.M.D., to Lucy Innes, second daughter of H. R. P. Carter, Esq., of Madras.

BROWNE—WHITAKER.—On the 27th ult., at the Parish Church, Leytonstone, Essex, William Browne, L.R.C.S., L.R.C.P.Ed., of Stirling, to Agnes Mary, fourth daughter of the late Jas. Whitaker, of Elmfield, Huddersfield.

CHEYNE—SERVANTÉ.—On the 29th ult., at Christ Church, Gipsy-hill, by the Rev. R. Allen, Vicar, assisted by the Rev. C. W. Servanté, brother of the bride, W. Watson Cheyne, M.B., F.R.C.S., of 59, Welbeck-street, W., to Mary [illegible], only daughter of the late Rev. Wm. Servanté.

IRVINE—HOGG.—On the 27th ult., at Hilton, near Perth, R. W. Irvine, M.B., C.M.Ed., of Pitlochry, to Minnie, youngest daughter of the late James Hogg, of Lowvalleyfield, Culross.

JESSOP—ROGERS.—On the 27th ult., at St. Pancras Parish Church, Edward Jessop, M.R.C.S., L.R.C.P., of Retford, to Ada, youngest daughter of Thomas Arnold Rogers, of Endsleigh-street, Tavistock-square.

POLAND—DENHAM.—On the 31st ult., at St. George's Church, Edinburgh, by the Rev. Archibald Scott, D.D., Minister of the Parish, John Poland, F.R.C.S., of St. Thomas's-street, S.E., third son of R. H. Poland, Esq., Eliot Vale, Blackheath, to Mary Roberts, youngest daughter of James Glover Denham, Esq., of Castle-terrace, Edinburgh.

POTTER—DU BOIS.—On the 29th ult., at St. Mary's, Bryanston-square, by the Rev. C. H. Bowden, M.A., assisted by the Hon. Rev. Canon Leigh, Henry Percy Potter, F.R.C.S.Eng., Kensington Infirmary, W., to Annie Blanche, third daughter of the late Douglas Du Bois, of Thurloe-square.

DEATHS.

ALEXANDER.—On the 27th ult., at Trinity-square, S.E., on his 67th birthday, Charles Linton Alexander, F.R.C.S., L.S.A.

DAUBENY.—On the 26th ult., at San Remo, Italy, Henry Daubeny, M.D., in the 67th year of his age.

LISTON.—On the 28th ult., at her residence, 10, Glengyle-terrace, Edinburgh, Christina, widow of Robert Liston, F.R.S., F.R.C.S., &c., in her 86th year.

MASSEY.—On the 29th ult., at Greek-street, Stockport, Thomas Massey, M.R.C.S., aged 86.

MYRTLE.—On the 2nd inst., at 348, Oxford-road, Manchester, Andrew Scott Myrtle, jun., M.D., aged 24.

PROSSER.—On the 30th ult., at Bromsgrove, Worcestershire, Roger Prosser, L.R.C.P.Ed., M.R.C.S., aged 51.

RAWES.—On the 29th ult., at Bath, William Wilson Rawes, Deputy Inspector-General of Hospitals, Madras Army, in his 71st year.

STARTIN.—On the 26th ult., at Surbiton-hill, the wife of James Startin, of 17, Sackville-street, Piccadilly, aged 37.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, February 7.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.
ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual communications by Messrs. A. S. Underwood, E. G. Betts, Storer Bennett, C. D. Davis, J. Ackery, W. H. Coffin, L. Matheson, C. Rollins, and Willoughby Weiss.—President's Inaugural Address.
SOCIETY OF ARTS.—8 P.M. Dr. J. L. W. Thudichum: The Diseases of Plants, with special regard to Agriculture and Forestry (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Lennox Browne: Excision of Half the Larynx.—Mr. Stephen Paget: Cases of Parotitis after Abdominal Operation.—Mr. Hugh Smith: Rupture of Aneurysm into Pericardial Cavity.

Tuesday, February 8.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Mondays and Thursdays, 9.30 A.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Respiration.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Cant: Clinical Observations on Induration in the Primary Lesion of Syphilis in Women (communicated by Mr. Holmes).—Dr. Hebb: A case of Actinomycosis Hominis (communicated by Dr. Sturges).
ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Lieut.-Col. Sir Charles Wilson: Notes on the Tribes of the Nile Valley North of Khartoum.

Wednesday, February 9.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Mr. John Moir: Statistics of Small-pox Cases in the West Ham Hospitals during the Epidemic of 1884 and 1885.—Dr. John Macpherson: A Memorandum on Notices of Cholera in India before 1817.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Presidential Address by the Rev. Dr. Dallinger, F.R.S., on Recent Optical Improvements in the Microscope, and the operation of the Darwinian Law amongst the Minutest Organisms.
SOCIETY OF ARTS.—8 P.M. Mr. A. Gordon Salamon: Purity of Beer.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Mr. Bland Sutton, Dr. Fancourt Barnes, and others. Dr. Charles E. Fitzgerald: The Use and Abuse of Pessaries.

Thursday, February 10.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. A. W. Rücker: Molecular Forces.

Friday, February 11.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF ARTS.—8 P.M. Dr. George Watt, C.I.E.: The Economical Condition of India.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Nephro-lithotomy—discussion on papers read at the last meeting by Mr. Henry Morris, Mr. Marsh, and Mr. Bennett.—Dr. Hughlings Jackson: A case of Crural Monoplegia from Subcortical Disease.—Dr. Carrington: A case of Rheumatic Hyperpyrexia. Living Specimens:—Dr. A. H. Robinson: A case of Charcot's Joint Disease.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Mr. Edward B. Poulton: Gilded Chrysalides.

Saturday, February 12.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Carl Armbruster: Modern Composers of Classical Song—Rubenstein, Raff, and Grieg (with Vocal Illustrations).

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

AN ITALIAN DAILY MEDICAL JOURNAL.

AN Italian correspondent informs us, with reference to a letter appearing in our issue of Jan. 1st, that a daily medical journal is published in Naples, called *La Riforma Medica*, which enjoys a considerable circulation. The editor has recently issued a notice that prizes consisting of gold medals will be awarded to the students who shall contribute the best original articles on various branches of medical science. The awards are to be adjudicated by a commission of professors of the different universities.

Med. Staff.—Our correspondent has completely misapprehended our views. We believe also that his opinions on the subject of rewards are not those held by a large majority of the officers.

Mr. Brinsley is referred to a general notice at the head of this column.

TO ALL WHOM IT MAY CONCERN.

To the Editors of THE LANCET.

SIRS,—As an advertiser and answerer of advertisements in your journal I will ask you to be so good as to give a place to the few remarks I make on the above subject.

I have answered several advertisements in your journal, in each case sending an enclosed stamp for reply, along with a copy of my testimonials. I have asked the persons to whom I wrote to be so good as to return my testimonials and favour me with an early reply. I think if persons who insert any advertisement were for a moment to seriously consider that such an act entails a certain amount of responsibility, and to look on the matter as a business transaction, they would at once see that it is neither business-like nor courteous to leave a reply unanswered, especially when a stamp is enclosed for a reply, and a request made to have one's testimonials returned. Those who advertise should also bear in mind that they are not the only persons who do so; and that the person who answers their announcements may very probably be in communication with others, who also desire to come to a settlement. When, therefore, an early reply is asked for it ought as far as possible to be given, especially when it is particularly requested, and a stamp enclosed to defray postage. Surely it would be no hardship—and very little trouble in such cases—to return testimonials, and enclose a slip of paper with "declined with thanks" when one is not disposed to have any more to do in the matter. It is alike to the interest of the advertiser and those who reply to adopt such a course. I feel sure the subject only requires to be mentioned to draw the attention of your *clientèle* to the matter.

I am, Sirs, yours truly,

Jan. 20th, 1887. ADVERTISER.

Subscriptions may be forwarded to the treasurer, Mr. T. H. Bartleet, 27, Newhall-street, Birmingham, or to the secretaries, Messrs. Bennett May, 81, Edmund-street, and Jordan Lloyd, 22, Broad-street.

Mr. J. Holloway.—Our correspondent does not supply all the material which would enable a precise opinion to be given. When cold air is heated it requires increased moisture to prevent it from becoming dry and irritating. The amount of moisture required must necessarily depend upon the amount of increase of temperature resulting from the heating. The proper amount of moisture in air for breathing should be from 65 to 75 per cent. of saturation, and the absolute amount which should be added to each cubic foot of air thus warmed can be calculated from the following table, which gives in grains troy the moisture contained in each cubic foot of air when saturated at different degrees of temperature:—

Degrees Fahr.	Grains of vapour in cubic foot.	Degrees Fahr.	Grains of vapour in cubic foot.
10	·8	60	6·0
20	1·3	70	8·0
30	2·0	80	10·0
40	2·9	90	15·0
50	4·0	100	19·0

A Smoker.—We may perhaps take an early opportunity of going fully into the subject.

Mr. W. H. Bull.—Miss Wardell's Institution at Brockley-hill, Stanmore.

"OBSTINATE CONSTIPATION IN AN INFANT."

To the Editors of THE LANCET.

SIRS,—If your correspondent, "O. P. Q.," will read Dr. Cheadle's lecture on the Pathology and Treatment of Chronic Constipation in Children, contained in THE LANCET of Dec. 4th (pp. 1063-1064) and 11th (pp. 1116-1118), 1886, he may find some hints for treatment that may be useful. I have acted as locum tenens for a doctor who used to treat constipation in infants, generally with success, with a mixture as follows:—℞. Res. podophyllin, gr. i.; sp. rect., ʒii.; syrup. aurant., ʒii.; aqua ad ʒiss. One teaspoonful to be taken every night. I saw a child of six years old that received much benefit from taking two-minim doses of tincture of nux vomica in water daily, as recommended by Dr. Ringer. Dr. Goodhart, in his Manual on Diseases of Children, first edition, p. 41, draws attention to the association of small fissures about the anus with obstinate constipation, and recommends "the lower inch of the bowel and anus to be well greased with an ointment composed of equal parts of lead, zinc, and mercurial ointments, or the fissure may be dusted with equal parts of calomel and oxide of zinc."

I am, Sirs, yours faithfully,

Jan. 29th, 1887. W. F. F.

Mr. George Pycroft (Kenton).—We certainly cannot commend the practice referred to. If unwelcome, the book might be returned.

LATERAL CURVATURE.

To the Editors of THE LANCET.

SIRS,—A patient of mine, a girl aged fourteen years, is suffering from lateral curvature of the spine. The deformity is not very much at present—in fact, it was only about a month ago that her parents first noticed anything the matter. There is, however, a distinct bulging of the ribs, with projection of the lower end of the scapula on one side. Could you kindly inform me of any form of strap or other apparatus which would be of use in such a case? I am, Sirs, yours faithfully,

Jan. 26th, 1887. GRADUATE.

*** We would not advise any strap or other appliance of the kind, but regular and proper exercise of the spinal muscles, together with the correction of bad habits in standing and sitting, and general tonic treatment.—ED. L.

MEDICAL APPOINTMENTS IN THE COLONIES.

MR. J. GOODRIDGE ANDERSON writes:—"It will be very necessary for those who think of taking appointments in the colonies to be quite sure of what they are going to before they go to it and find themselves in a strange country, among strange people, under circumstances very different from what they had been led to expect, and without the means of getting home again. I see in the table published in your last issue that the salaries in the Windward Islands are stated to range from £200 to £100. This is not correct. The salaries in Tobago are £100 a year. They were £200; but some year or so back, money being scarce, and it being discovered that the Act under which the medical officers were appointed set forth that they should be paid salaries not exceeding £200 a year, it needed only a stroke of the governor's pen to make those salaries £100 a year. I need hardly say that the stroke was made. I know little, beyond hearsay, of the medical services of the other West Indian colonies; but they are mostly, if not all, Crown colonies, in which the Crown—i.e., the governor for the time being—is paramount. In the larger of these colonies the salaries offer a certain compensation for what the holders of medical appointments have to put up with in connexion with them; in the smaller colonies there is no compensation whatever, and they should be avoided by every man with even the smallest modicum of self-respect."

G. H. F.—The question is a difficult one to discuss, though many attempts at its elucidation have been made.

Doubtful—No; there are many reasons why the question should be decided in the negative.

M.B.—The L.S.A. cannot at present be counted as a double qualification.

Viator.—Mr. L. Bruck, 35, Castlereagh-street, Sydney.

THE GENERAL MEDICAL COUNCIL AND UNQUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—Can you lend your powerful aid in behalf of a body of men who, through the proposed action of the General Medical Council, are about to become the victims of a, to them, sweeping and cruel law abolishing their vocation? Are scores of hard-working and valuable men to their employers to be thrown on the world, many of them married and with families depending on them; some, if not the greater number, too old to embark in any other walk of life; few, alas! with the means? If it is made illegal for a medical man to employ an unqualified assistant, although many general practitioners prefer to do so, and these men are deprived of their livelihood with their wives and families, what is there before them? The workhouse? Are we all to be ruined by the profession many of us have served so long and faithfully? Many of us are working our way slowly into the legitimate ranks of the profession, perishing ourselves, depriving ourselves of small luxuries, saving what we can of our not too liberal salaries, so that we can pay for lectures and hospital, and still maintain the appearance of gentlemen. Others, who have unfortunately married and have families, have no such hope, but manage to live decently and respectably. Some of the very men who are now our most bitter enemies have been unqualified assistants themselves. They used the same stepping-stones; but now they have arrived safely on the other bank, they would kick away the stones, so that no one else may cross, except by the new bridge. Is there no way by which, at all events, the men who are now holding the unenviable position of unqualified assistants may be protected? Could not these men, as has been suggested by a writer in your columns, be allowed to register as assistants, and no fresh admissions be allowed after a certain date, confining them to holding appointments as general assistants, not allowing them to practise "under cover," and striking them off the Register if found doing so. The race would soon die out. Many in course of time would qualify, and the others would gradually disappear. Such an act was allowed in 1815—the same almost—by the pharmaceutical and dental professions, and last year by the Canadian authorities. These men are to be registered as medical practitioners on passing a practical examination before three medical men and payment of a fee. If you would lend your powerful voice in the settlement of this, to many men, vital question, their deep gratitude would be due to you. It has been suggested that a representative meeting of *bond-fide* unqualified assistants be held in London, and resolutions forwarded to the General Medical Council. This would, I think, be a wise proceeding.

Entreating your advocacy for a deserving body of men,

I am, Sirs, yours faithfully,

Jan. 18th, 1887. UNQUALIFIED ASSISTANT.

MEDICAL NEIGHBOURLINESS.

T. B. B.—When a medical man is called upon in an emergency to see the patient of a medical neighbour who chances to be out of the way, it is his duty to act for his neighbour, and to transfer the case to the ordinary attendant. Every medical man occasionally needs neighbourly kindness of this sort, and there is something wrong in any neighbourhood in which it cannot be relied on.

Dr. Blackmore (Portsmouth).—The paper has been received.

THE UNIVERSITY OF BERLIN.

THE number of students at the University of Berlin increases yearly. It is stated that during this winter more students have matriculated than in any term since the foundation of the University in 1810. In the theological, medical, law, and philosophical faculties there are 5357 regularly matriculated students, and, adding the other schools which are also parts of the University, the number rises to the aggregate of 6880. Every country of Europe, except a few minor Turkish provinces, is represented, and also are Asia, Africa, Australia, and America. The United State, is represented by 149 students, Russia by 98, Switzerland by 80, Great Britain by 18, Japan by 21, and Turkey by 7.

Mr. Thos. Edwards.—If such diseases as those mentioned were cured by medical measures, the power of legal recovery would be good.

Mr. D. Jones (Bicester).—The West-end Hospital, Welbeck-street, would probably receive the case.

Mr. H. E. Facey.—We do not copy letters from the pages of our contemporaries.

M. R. C. P.—The proposition appears to us to be impracticable.

THE CLIMATE OF THE SOUTH-WEST OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—In your issue of Jan. 29th you have an interesting reference to the blossoming of the primrose in the open air during the present month, and you interpret the true value which flowers furnish of the meteorological and geological conditions in which they have been placed. It is a subject in which so many of your readers are interested, that I trust you will find room to record the fact that at the present date the subjoined plants are in blossom in the sheltered valleys of this district. In addition to the veronica, in variety, there are the primrose, violet, snowdrop, and the following herbaceous plants and shrubs now in bloom—viz., Escallonia macrantha, Gentiana verna, Genista fragrans, Coronilla iberica, Erica codonodes, Anemone fulgens, Primula purpurea, Godetia Albemarle, Cheiranthus cheiri, Berberis Darwinii, Rhododendron dauricum, the old "monthly" rose, and red carnation.

I am, Sirs, your faithful servant,

EDWYN SLADE-KING,
Ilfracombe, Jan. 29th, 1887. Medical Officer of Health.

SCIENCE IN THE NURSERY.

To the Editors of THE LANCET.

SIRS,—I learn from the *St. James's Budget* that an incubating experiment is now proceeding at Glasgow upon three children who made their appearance in the world rather earlier than was good for them. What a grand opportunity it is for testing General Pleasanton's (of Philadelphia) plan, and of the alleged efficacy of the mazarine blue glass being inserted alternately with the usual plain white in the nursery windows of the olive branches, as explained in his very interesting little book published by Messrs. Trübner and Co., Ludgate-hill.

I am, Sirs, yours faithfully,
Saltburn-by-the-Sea, Jan. 26th, 1887. H. G. J. DE S.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—May I venture to appeal through your columns to the generosity of our profession on behalf of the aged widow (82) of a surgeon, long since dead. She is in urgent need of assistance to enable her to pay debts contracted during a long illness. The smallest sum will be thankfully received and acknowledged by

Yours faithfully,
THOMAS BROOKES, M.R.C.S., L.S.A.
Whitchurch, Tavistock, Devon, Jan. 27th, 1887.

Harveian Lectures
ON
CANCER OF THE UTERUS.

BY J. WILLIAMS, M.D. LOND., F.R.C.P.,
OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE III.

GENTLEMEN,—Most of the cases given were perhaps too little advanced to manifest secondary growths discoverable by clinical investigation, and in only three of them was the disease watched to the end and a post-mortem examination made. In these the glands along the internal iliac vessels, and in one those along the spine, were cancerous. The sacro-uterine ligaments were not affected in any of them, but the cellular tissue around the cervix and in the broad ligaments was diseased in two.

Small cancerous masses are sometimes seen on the interior of the body of the uterus in cases of primary cancer of the cervix. These are sometimes spoken of as secondary deposits. It is, however, difficult to see how secondary deposits can be produced in the body of the uterus from a primary cancer of the cervix. Neither the arrangement of the blood-vessels nor that of the lymphatics can explain it, and it appears more reasonable to regard such formations as new growths from independent centres—such as I have described as occurring in the cervix itself. They are not often met with.

Age seems to have a considerable influence on this form of cancer, though no age above twenty-eight years excludes it. The oldest patient was eighty-one, the youngest twenty-nine. There was only one under thirty; there were six between thirty and forty, and fifteen between forty and fifty; there was one between fifty and sixty, and one over eighty. So that during the ten years in which the menopause generally occurs this disease is far more rife than at any other period of life; it is next most frequent between thirty and forty; and it is comparatively rare before thirty and after fifty. The history of the menstrual function throws no more light on this form of cancer than it does on that of the portio vaginalis. The age at the time of marriage and the duration of married life throws just as little.

With regard to childbearing, it is to be noted that two, or a twelfth of the whole number, had never been pregnant; four had had one child; two had had one child and one miscarriage; two had had two children; one had had two children and abortions; one had had three children; one, three and one abortion; one had had four children; one, five and five abortions; one, seven; one, eight; one, eight and five abortions; one, eleven and one miscarriage; and one, thirteen and two miscarriages. So that fourteen out of the twenty-four had been pregnant fewer than five times.

The characters of the labours, again, appear to have no influence on the production of cancer. Of sixteen cases in which this point was investigated, eleven had had good, one had had lingering, and five had had difficult labours. Only two of these required the use of the forceps: one five times, the cervix being probably cancerous on the last occasion; and one once, the cervix being probably cancerous at the time. So that we have two cases only among the whole number in which labour had been instrumental.

The chief symptoms of cancer are hæmorrhage, pain, discharges, and wasting. Hæmorrhage was present in greater or less amount in all the cases. Its quantity, however, varied greatly, and the time of its appearance with respect to the onset of the disease not less. In some it began at a very early stage, while in others it set in only when the growth had attained a large size. For instance, in one case hæmorrhage had been present for three years when first seen; the disease affected the whole of the cervix, but the surface of the portio was still intact. In this instance the hæmorrhage began probably soon after the growth commenced. In another case, again, where there was a large growth in one lip, hæmorrhage had been present for three weeks only. Pain may be absent throughout; it was absent, or present in a very slight degree, in six of these cases. When present it is often relieved by the onset of bleeding and by lying down. Discharges are commonly present; four of those with advanced disease had none, six had an offensive discharge, five a watery, two a greenish, four a yellow, and one a white discharge. Wasting was present in varying degrees. Eight of the patients had lost much flesh, six very little, and all these presented a somewhat advanced stage of cancer, except the one who was eighty-one years of age. In some cases extreme emaciation was present, while in others, even at the time of death, there was an abundance of subcutaneous fat. Micturition was frequent in only five of all the cases: in the two cases in which the disease began near the internal orifice, in two in which the whole of the cervix was diseased, and in the old woman. As a rule, when the disease attacks the lower part of the cervix the bladder is not disturbed until a very advanced stage of it.

There is a view of the etiology of cancer of the cervix and portio vaginalis which has been recently brought into prominence, chiefly because it has been made the ground for procedures of an operative kind: I mean the view that lacerations of the cervix are a cause of cancer. If this view be correct, it has a very important bearing on treatment of a prophylactic character; on the other hand, if it be untrue, it has a no less important bearing in an opposite direction. It has been said again and again that lacerations of the cervix are the cause of cancer of the lower part of the uterus, and that the cure of the lacerations by Emmett's operation is a means of preventing the development of the disease. Now, what is the evidence with regard to this view? Are there any known facts which favour or oppose it? One fact which favours this view, or which is supposed to favour it, is that cancer is frequent in women who have had many children. Laceration of the cervix occurs so frequently in first labours—and probably far more frequently than in subsequent ones—that we cannot regard multiparity as the cause of lacerations as against uniparity. Indeed, it may fairly be said that when laceration is present, the time when it was produced was during the first labour; and if this be true, and if it be also true that laceration of the cervix is a cause of cancer, uniparity should be as frequent a cause of cancer as multiparity; and if multiparity is really a cause of cancer as against uniparity, then we must explain the fact in some other way than by the laceration present. In the next place, cancer is often present in association with laceration. But association does not necessarily involve the relation of cause and effect—a fact too frequently lost sight of in the study of uterine disease. It is said, moreover, that lacerations occasion the development of cancer by reason of the irritation to which they give rise. Now, if this be true, we should expect to find the starting-points of cancer to lie at the place of greatest irritation—that is, in or close to the tear, or in the surface of the irritated part. But what are the facts? I have described to you cases of cancer of the portio vaginalis and of cancer of the cervix proper in association with lacerations, but in no instance have I seen it attack the lacerated part primarily. Indeed, it appears to avoid it, and to invade it only after the rest of the cervix has become involved in the disease. The tear is the last part to be attacked. But it may be said that although cancer does not commence in lacerations, yet it begins in the everted or irritated surfaces of the lips. I have been able to trace cancer primarily to the surface in no single instance, except in the variety of squamous epithelioma, when it necessarily begins on the surface. But in cases of squamous epithelioma the disease begins on any part of the surface of the vaginal portion, except perhaps the edges of the tear—a fact which does not favour the view I am discussing. When cancer attacks the cervix proper, it begins, in so far as I have been able to discover, in the glands in the substance of the cervix, and a layer of non-cancerous glands is often, though not always, seen between the disease and the surface. This is the condition present whether laceration exists or not, and the fact that the disease begins in the same situation in the lacerated and the non-lacerated cervix militates against the view that lacerations are an important factor in the development of cancer. Moreover, if irritation be such a very frequent cause of cancer of the uterus as is sometimes maintained, the disease should be frequently met with in the procident uterus; but this, again, is not the case. In some hundreds of cases of cancer of the uterus which I have seen there was but one in which the organ was preci-

Digitized by Google

dent. It appears to me that the facts at present known tend to show that lacerations play no important, if any, part in the causation of cancer.

CANCER OF THE BODY OF THE UTERUS.

The next part of our subject is cancer of the body of the uterus. This is a form of cancer which is much less common than that of the cervix, and indeed it was at one time thought that cancer never attacked this part of the organ primarily. It is certain that the disease occurs much more frequently than is generally supposed. Pichot has collected forty-four cases of what he terms cancer of the body of the uterus. They are all apparently cases of malignant disease, but there is no sufficient evidence that they are all cases of cancer. In saying this I wish it to be understood that no case can be scientifically admitted to be a case of cancer unless sections of the growth have been submitted to examination with the microscope. This brings us down to very recent times—past the time when microscopic examination of tissues meant the examination of scrapings and the search for characteristic cells; down to the time when the arrangement of the various elements of a growth were examined into and their relations observed in their undisturbed position in sections. Ruge and Veit have described more or less fully twenty-one cases in which the nature of the disease was established by microscopic evidence. I have seen twelve cases which were believed to be malignant disease of the body of the uterus, but in only three of them was the growth ascertained to be cancer by microscopical examination, and consequently these three only are of sufficient value to serve my purpose in these lectures. It would only lead to confusion were I to introduce cases as basis for description around the nature of which—that is, whether they were sarcoma or carcinoma—any doubt rests. These cases, together with those recorded by Ruge and Veit, will mainly form the material for the description of cancer of the body which I shall give you.

CASE 20.—The patient was a widow aged fifty-two. She was admitted into University College Hospital complaining of a profuse and offensive vaginal discharge, which excoriated and caused swelling of the external parts. She was a nurse, and eight years previously she received a shock through the sudden death of a patient. This brought on a sanguineous discharge, which has continued more or less ever since. She has been losing flesh for some time, but more especially during the last three months. She was married at twenty-two. Her husband lived eight years. She had one child twelve months after her marriage, and no miscarriages. She said that during the lifetime of her husband she had sore-throat, lost her hair, and took medicine which made her gums sore and teeth to ache. She had a polypus removed from the womb five years ago. She began to menstruate in her twelfth year, was poorly every three weeks, losing a good deal, with bearing-down pain in the abdomen. After the birth of her child the flow returned regularly, but in far greater quantity, and with much more pain than before her marriage. She has suffered from leucorrhœa since she was fifteen. There was no history of cancer in her family.

On admission in January, 1881, she was pale, anæmic, and emaciated; the pulse was 100, and temperature 99° F. The uterus appeared to be of the normal size, but less movable than natural. The cervix was normal, except that a small villous growth could be felt in the os. The outline of the body could not be made out, and the sound was not used. Examination by the rectum revealed several nodules apparently growing from the posterior wall of the uterus. There was little or no tenderness.

The villous growth projecting in the os was removed. On Feb. 5th she had several rigors, and her temperature went up to 105°, and remained above 100° until Feb. 10th. This attack of fever was accompanied by severe pain in, and exquisite tenderness over, the whole of the abdomen. A month afterwards she had a similar attack, but without rigors. With these exceptions her temperature remained between 99° and 100°, and her pulse was over 100 a minute. She complained also of globus and other symptoms usually called hysterical. In March there was œdema of the vulva, and a hard growth about the size of a hazel-nut projected slightly through the os. There was copious greenish-yellow discharge with some blood. She gradually became weaker, and died on March 20th. At the necropsy the small intestines were adherent to the fundus of the uterus and the posterior wall of the bladder. There was a small cyst at the end of the Fallopian tube. At the posterior part of the uterus there were several nodules, two of the size of cherries, others smaller, projecting into the peritoneal cavity. These were of a whitish colour, with injection around them. The upper half of the posterior surface in the middle and the fundus were white and bloodless. The rest, especially the sides, were of a purplish colour, with the veins injected. There was a big nodule on the anterior surface where the intestines were attached, and a communication which admitted the thumb was found between the adherent intestine and the cavity of the uterus. The ovaries were white and atrophied. The uterine wall varied from one-half to one inch in thickness. The cavity of the uterus was a fetid abscess; its surface was irregularly nodular and of a greyish-green colour; beneath this was a layer of highly vascular tissue, and still deeper the altered uterine tissue. The cancer was glandular.

CASE 21.—This patient was fifty-two years of age, and was admitted into the hospital in January, 1884. She had enjoyed good health until fifteen months before, and was a strong woman. "Menstruation," which had ceased about nine years previous to this date, recommenced, and recurred about every three weeks. At this time the flow was of the ordinary colour and not profuse. It lasted at first for two or three weeks, but latterly only for one day. For the last five months bleeding had ceased entirely, but a yellow offensive discharge had been continuously present. Some time after the bleeding commenced labour-like pain was felt at the bottom of the stomach and back, but since January, 1883, the pain had been seated principally in the right side of the pelvis and down the right leg, shooting at times to the left side. For some years before her illness the patient suffered from pain in passing urine, and micturition became frequent in June, 1883, for which she had a growth removed from the "entrance to the bladder." Micturition continued to be frequent after the operation. There had been no difficulty or pain in defecation. She had lost much flesh during the previous fifteen months. Menstruation began at fifteen, was regular and painful, and ceased at forty-three. She had been twice married; first at twenty-three. During her first marriage she had four children; one child and one miscarriage during the second. All her labours were natural. One sister died of cancer of the womb in an asylum.

On admission the patient was thin, but not greatly emaciated. The perineum was excoriated. There was a small superficial ulcer on the inside of the right labium. On the vaginal wall were about a dozen small greenish patches, which felt slightly raised to the finger; there was no loss of tissue. The anterior lip of the uterus was thickened by a growth which projected into the cervical canal, which bled on examination. The uterus was freely movable; the body was a little enlarged, thick, and roundish, so that the whole of the uterus—body and cervix—approached a globular form. There was no thickening anywhere in the pelvis. The sound passed in three inches. The chief thickening was in the anterior wall. The cavity of the body was considerably enlarged; the sound could be moved about freely in it. A good deal of bleeding followed.

The uterus was extirpated. The parts removed consisted of the whole uterus, with the exception of a small irregular rounded portion situated on the left side of the middle line, and reaching almost to the origin of the Fallopian tube. The margin of the opening when this piece was absent was lacerated and nodular. The absent portion was about one centimetre in diameter. The whole organ was increased in size—laterally and antero-posteriorly. The external os and cervix for the lower two-thirds were normal in appearance, but soft and pale. The cavity of the uterus contained some dirty muco-pus. The surface was occupied by a nodular new growth, which on section was seen to extend into the muscular wall as pinkish-white granular-looking growths, the tissue which it invaded appearing gelatinous. The nodules of new growth were irregularly scattered over the inner surface, but were thickest on the right side of the posterior wall. Outside the new growth everywhere except at the point mentioned was a layer of muscle and peritoneum, which varied from one to three millimetres in thickness. A month after the operation the patient died. The wound had almost entirely healed, but there was a small abscess in the remains of the right broad ligament. In the small intestine were several small fistulous openings, which were connected with the scar of the operation. The kidneys and ureters were normal; but the bladder was in a state of chronic inflammation.

Digitized by Google

CASE 22.—The patient, a single woman, aged sixty-three, was admitted into University College Hospital in January, 1883. She said that she had been losing blood from the vagina occasionally for two years, but not much until March, 1882, when she lost a great quantity, and since then she had been continually losing more than she had from the commencement of her illness until that date. She had fainted several times from the loss of blood. She suffered no pain until the previous March, but since that date she had suffered pain on and off in the bottom of the back and stomach; it was twitching in character, and never lasted more than a minute; it was never severe enough to lay her up, and was not made worse by walking. After the bleedings there was a slight yellow offensive discharge. Micturition had been at times frequent, and sometimes scalding. The patient had suffered for two months from acute eczema of both arms. She had lost much flesh since her illness; her appetite was good. Menstruation began in her thirteenth year; usually regular and profuse, but without pain. It ceased in her fifty-fourth year. She saw nothing afterwards for six years; then she had a slight bleeding twice; after that it ceased for one year, and since that time she had bled frequently. There was no history of cancer in her family.

On admission, she was well nourished and fat. The hymen was intact and the vagina senile. The body of the uterus was large and nodular, and filled the pelvis; it could be felt above the pelvic brim, and it appeared to extend further to the left than to the right. The cervix was far back, very short; the lips were softish. There was no tenderness. The vagina contained a dark-brownish very offensive discharge. Temperature 98·4° to 99·6° F.

The cavity of the uterus was scraped, after which the bleeding and discharge ceased for some time. She ultimately died in the cancer ward of the Middlesex Hospital, under the care of Mr. Henry Morris, through whose courtesy, together with that of Dr. Kingston Fowler, I am enabled to give an account of the appearances found at the necropsy, and a drawing of the uterus:—The body was well nourished. There were several firm adhesions between the omentum and the parietal peritoneum. A large swelling having the appearance of a uterine fibroid was seen at the lower part of the abdominal cavity. The intestines in the middle line of the abdomen were matted together, forming a sac, which on being torn open was found to communicate with the bowel, and appeared to be the seat of a slight fæcal accumulation. The lungs contained several secondary cancerous nodules scattered over the pleural surfaces. Numerous minute secondary deposits were found on the surface and in the substance of the liver. There were three cancerous deposits of the size of peas on the surface of the right kidney. In other respects the kidneys were fairly healthy. The uterus was large and its walls contained three fibroid tumours, two of which were calcified and of the size of walnuts, and one was as large as a man's fist. The walls were much thickened. The inner surface of the body was everywhere cancerous, irregular, and ulcerating. The cervix was healthy. The cancer had not invaded the fibroid growths, but had penetrated through the part of the wall free from fibroids into the broad ligament on the left side, and formed a large mass in that situation, apparently involving the ovary and Fallopian tube. The Fallopian tubes on each side were inflamed and contained pus. The cancer was glandular, and the glands presented a very remarkable appearance. Many of them were coiled up in spaces so that the spaces appeared in section to be filled by circles of columnar epithelium without any connective tissue framework. In many places the epithelial cells appeared normal, while in others they were altered, many-shaped, and more or less broken down. The nodules in the liver presented a glandular structure similar to that of the glands in the uterus.

Cancer of the body may be diffuse or circumscribed. The diffuse form is much the more common; indeed, I have not met with an instance of the circumscribed. Several cases of the latter, however, have been described. They assume a polypoidal shape, and the uterine wall at their base may be healthy, or they may form sessile tumours and grow in the substance of the uterine wall, projecting into the uterine cavity like a submucous fibroid. In the former case the disease may have originated in a polypus already formed, as in Case 19, in which a mucous polypus of the cervix was removed while undergoing the process of becoming a cancer; or it may develop from the first in the form of a polyp. In the second case, when the cancer dips deeply into the uterine wall, it is not improbable that it begins in the deeper portions of the gland, as it so often does in the cervix, and then as it grows it becomes more and more superficial and prominent in the uterine cavity; at the same time it penetrates deeper and deeper into the uterine wall. The further growth of the polypoid form is said to be, not superficial, but in a radial direction towards the peritoneum. The polyp may break down and disappear and leave a mass of cancer in the uterine wall, but connected with the surface. In this way Ruge and Veit explain the origin of circumscribed masses in the uterine wall described as primary, and it is in many cases probably a correct explanation; but there is no impossibility, and indeed no improbability, that cancer may begin in the deeper portions of the uterine glands and there form nodules in the wall just as we found to occur in the cervix, for the uterine glands are known to enter deeply into the muscular wall of the body of the uterus. The diffuse form affects usually the whole of the inner surface of the body. Whether this is the case from the beginning, or whether it is the result of its mode of growth, is not known, and is difficult to determine. In some cases, however, a part of the surface escapes. The cervix is generally respected until a late period. The surface is villous, rough, and ulcerated, or covered with warty nodules, sessile masses, or polypi. The uterus is usually much enlarged; sometimes, however, the enlargement is not great, and even very slight; the wall becomes thickened and hypertrophied by a process, it is said, similar to that which takes place during early pregnancy. As the cancer grows, the successive deeper layers of the wall become involved, and the muscular part becomes thinner and thinner. The cavity of the uterus is in some cases considerably elongated and deformed, in others but little; in some, after the disease breaks down the cavity increases in capacity. In some cases, or in some part of the uterine surface, the disease is quite superficial, the decidua not being much thickened, although diseased throughout, as in Case 22. The disease grows from the glands; it may perhaps begin also in the epithelium of the surface. This has not been actually observed, but the fact that the whole of the surface is generally involved—at least in the specimens which have been examined—is in favour of this mode of origin.

Several cases have been recorded in which fibroid tumours were present with cancer; one of my cases was such. In this case the cancer clearly grew from the uterine glands, and had not invaded the fibroid. Klob, however, has recorded a case in which a fibroid was present and cancerous. He was of opinion that the cancer had commenced in the fibroid. His case is imperfectly recorded, and the growth had begun to break down and to slough, so that the tissues over it had been destroyed, and were in a condition which precluded the possibility of establishing the view of the case adopted by Klob. Moreover, all the histological evidence collected goes to show that cancer of the body begins nowhere except in the epithelium of the surface or of the glands. It has further been shown by the observations of Buhl and Ruge that cancer may extend from the mucosa covering a fibroid and involve the fibroid itself.

The direction or lines of growth of cancer of the body appears to be in two directions—that is, such as to involve the surface and to spread into the deeper structures. The spread of the disease superficially is often stopped at the inner orifice of the uterus and the openings of the Fallopian tubes; and this, although not invariable, appears to be the rule. In some of my cases the cancer had passed the os internum and invaded the cervix; and in a specimen in the museum of St. Bartholomew's Hospital, already referred to, the disease had invaded the Fallopian tubes.

(To be concluded.)

STAFFORDSHIRE GENERAL INFIRMARY.—At the annual meeting of the governors of this institution, on the 28th ult., it was reported that the ordinary income for the past year was £2142, and the expenditure £2953. The books having been neglected, it was impossible to ascertain the number of patients who had been treated. A letter was read from Dr. C. H. Crawford resigning his appointment as physician to the hospital, and a resolution thanking him for his thirteen years' services, and expressing the regret of the board of governors at his retirement, was unanimously agreed to.

ABSTRACTS OF THE

Erasmus Wilson Lectures

ON

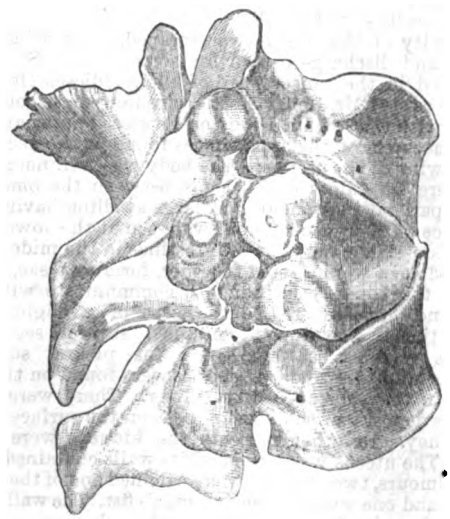
EVOLUTION IN PATHOLOGY.

Delivered at the Royal College of Surgeons of England,

BY J. BLAND SUTTON, F.R.C.S.,
ASSISTANT-SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE II.

SUPPRESSION OF PARTS.—(*Continued.*)



MR. PRESIDENT AND GENTLEMEN,—To the student of mammalian anatomy it has always been a somewhat remarkable fact that, whatever the length and flexibility of the neck, the number of cervical vertebræ remains almost constant; whereas in birds the reverse of this obtains, for the cervical vertebræ are extremely variable in number—a pigeon may possess thirteen or fourteen, but the swan has twenty-five, whilst in the extinct plesiosauria as many as forty cervicals existed in some species. Parker, in his valuable memoir, "The Development of the Green Turtle," has found that at one stage in the embryology of this form fifty-one somatomes are visible externally, but in the adult only forty-one vertebræ are developed, and an examination of the embryos in various stages clearly shows that seven somatomes in the neck and three in the caudal series abort. This suggests an ancestry from forms having a longer neck and tail than existing turtles, and the free suppression of parts indicates a modification by shortening of a form not unlike a plesiosaur. There is abundant evidence to support the view, which at first seems somewhat strange, that there exists an undoubted correlation between the hand and the number of the cervical vertebræ. In such vertebrates as birds the number of the cervical vertebræ and the saddle-shaped articular facets on their centra confer great mobility, and enables the beak to perform actions which rival in delicacy those of the hand and fingers. It is beyond all dispute that as the functions of the hand increase in precision so the number and size of the cervical elements of the spinal column diminish.

In the green turtle we saw that in the embryo several somatomes were suppressed, and now I shall enter upon a discussion to show that it is exceedingly probable that a similar suppression of somites occurs in man. In the first place, the disposition of the cervical nerves suggests that at least one vertebra has disappeared, for in order to harmonise the arrangement of spinal nerves in the cervical region with what pertains in other parts of the column an extra vertebra is requisite. Apart from these anatomical speculations, the observations of teratologists go to show that in the various regions of the column suppression of somites occurs. Professor Humphry[1] has drawn attention to Otto's observation of a spine in which there was deficiency of one-half of the eleventh dorsal vertebra; also a case described by Sandifort in which one-half of the seventh cervical and of the ninth and eleventh dorsal vertebræ is absent, the remaining half being wedge-shaped. Dr. Goodhart[2] has described a fœtal vertebral column preserved in the museum of the Royal College of Surgeons in which only four and a half cervical vertebræ can be made out. The malformation was associated with spina bifida. In the report of the Spina Bifida Committee of the Clinical Society a sacrum is figured in which the left halves of the first and third segments are absent. Willett and Walsham have published a detailed account of a remarkable suppression of vertebræ in a woman aged thirty-one dissected by them, and have referred to the specimens mentioned above. There is in the museum of the Middlesex Hospital a well-prepared skeleton of a presumably full-grown female, in whom there is lateral curvature of the spine caused by absence of one-half of a dorsal vertebra, apparently the third. (Fig. 5.)

Now, all these cases illustrate suppression of halves of the vertebræ belonging to spines presenting less than the normal number. It occasionally happens, however, that the half vertebra is in excess of the proper number. Thus in a case Rokitanski records in his "Pathological Anatomy" (vol. iii., p. 230) there were four half vertebræ, with their half arches and processes, too many. They were so placed on the two sides as to compensate one another, and cause four curves in the spine, two in the dorsal, one in the dorso-lumbar region, and the fourth involved the sacrum. This case, in conjunction with examples of supernumerary vertebræ occurring in the lumbar and sacral series, can only be explained satisfactorily by the hypothesis that during development mesoblastic somites become suppressed, which in the ancestors of man assumed a functional condition. Every human anatomist of moderate experience knows full well that the coccyx may consist of three, four, or five segments. That among mammals the caudal vertebræ may vary from three in the tailless monkey Inuus to as many as forty-six in Manis longicauda. If it is true that mesoblastic somites are suppressed in other parts of the column, but occasionally attain complete development, we ought to have them reappearing in the caudal series.

When we remember that some sharks and serpents may possess the prodigious number of three hundred vertebræ whilst man has only thirty-one, it necessarily follows that a great many segments of the spinal column have undergone suppression. This is still more marked when we compare the vertebral column of a frog with that of a fish, for the frog's spine is normally composed of only nine vertebræ, this being an unusually small number when compared with vertebrata in general. This fact alone would suggest that supernumerary vertebræ ought to occur in frogs. Bourne[3] has recorded a case in which a spine of Rana temporaria was composed of ten vertebræ, and Howes[4] has also described a similar specimen, which agreed in its main details with Bourne's case; in each the supernumerary vertebra was in the sacral region.

FIG. 5.

A half vertebra, from the spine of man. (After Reid.)

The notion of tailed men is usually treated with ridicule because on careful examination the supposed cases have turned out to be lipomata, spina bifida, or coccygeal tumours. But human fœtuses with tails are certainly met with. A careful examination and description of such a case is given by Gerlach;[5] in this case the tail not only contained striated muscle fibre, but notochord.

To return to the question of half vertebra. Professor Albrecht[6] has reported an anomaly of this character which occurred in a python (Python sebæ). The skeleton consisted of 333 vertebræ, but interpolated between the 195th and

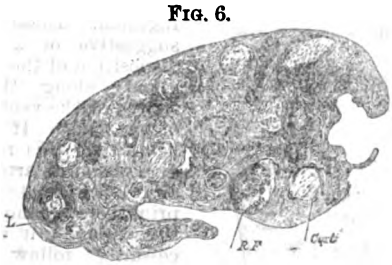
Digitized by Google



196th segment on the left side was an additional half vertebra. That in the normal course of events the vertebral centra are developed from a single nucleus is beyond all doubt; the parts have been carefully investigated by many observers: I have spent many hours in vainly hunting for two nuclei. It is equally certain that under exceptional circumstances two centres may be deposited and remain independent, as is the ordinary method in the ossification of the odontoid process of the axis. We must also remember that Müller detected two nuclei in the sacral vertebræ of birds.[7] Cope[8] has recorded the following interesting observation, that in an extinct batrachian found in the Permian formation of Texas the vertebral bodies are composed of two lateral pieces. The skeleton belonged to the order Ganocephala, and was named Eryops megalocephala. Between each vertebra a large intercentrum was developed, and the centrum of each vertebra consisted of two lateral pieces or pleurocentra. A similar condition of things existed in other strange forms belonging to this order. Thus there is good reason to believe that in the bilateral nuclei for the odontoid bone we have an instance of the retention of a primitive character, whilst in the occasional existence of a half vertebra, either in excess or diminution, or accompanied by disturbance in the normal ossification of the column, we have to deal with atavistic phenomena.

The conclusions which may be legitimately drawn from the foregoing facts may be summed up in a few brief statements:—1. During development the human embryo possesses more mesoblastic somites than are utilised in the formation of the permanent vertebral column. 2. At least one undergoes suppression in the cervical and lumbar region respectively, and probably many in the caudal segment of the column. 3. Occasionally one, or half of one somite, usually suppressed, may persist, and give rise to a supernumerary vertebra or half vertebra; or the suppression may extend beyond its usual limits, and the total number of segments in the column be fewer than usual. The diminution may affect only one half of a vertebra. 4. Under exceptional circumstances a vertebral centrum may arise from two distinct centres of ossification; this must be regarded as indicating the reappearance of an ancestral character. The study of the evolution of the spinal column teems with illustrations of the two laws—namely, those of *suppression* and *coalescence*.

Parasitic Fœtuses.—These may vary from a shapeless mass of varying proportions to a more or less fully formed individual attached to a perfect child. They are most common in the sacral region, and they may occur on any vertebrate from fish to man. A careful consideration of preserved specimens, as well as actual observations on the eggs of fish and amphibia tend to show that from a single ovum two embryos may be produced. This conclusion is supported by the following facts: 1. There is a continuous series of forms from one extreme of duplicity to the other. 2. Each embryo in a double monstrosity is smaller as a rule, but never larger than a normal single fœtus. If the duplicity were the result of the fusion of two ova, this condition would not be so constant. 3. Double monsters are invariably of the same sex. These facts render it probable that when twins occur of the same sex they are the products of a single ovum. Parasitic fœtuses and supernumerary limbs in the sacral region may be regarded as suppressed embryos, the autosite and parasite originating from one ovum.

We must now consider some points in the history of the mammalian ovary of considerable importance. The fecundity of fish is proverbial; it has been estimated that the roe of a cod-fish contains 9,344,000 ova. From various obvious intrinsic and extrinsic causes only a fraction of this number attain an adult condition, and in the same way only a small fraction of those actually hatched come to maturity. Of the very large number of eggs deposited by frogs only a small proportion of the tadpoles resulting therefrom attain an adult condition. The same is equally true of birds. Thus a bird which produces ten pairs of young during its lifetime (and this is far below the fertility of many birds) will, if we take its life at five years, increase to a hundred millions in about forty years. (Wallace.) Yet only a small proportion of the ova become mature. What is true of fish, batrachians, and birds is equally true of mammals, including man. Waldeyer has computed that the ovaries of a fœtus contain at birth no fewer than 300,000 ova. This is an exceedingly high estimate, and a very large margin must be allowed for portions of the same ovum appearing in two or more sections. Be this as it may, it is certain that if a section of the ovary of a fœtus be compared with one taken from a girl at puberty, diminution in the number of the ova is a most striking feature. This can only be accounted for in two ways: either many of them are suppressed without advancing beyond the fœtal stage, or they ripen and undergo retrogressive changes. As a matter of fact, the ripening of ova, the formation of Graaffian follicles and corpora lutea, commences very early, even at the seventh month of fœtal life. It appears that this fact was known to Valisneri in 1733; but attention was turned to this question in consequence of the writings of Carus (1837) and Ritchie (1842).[9] Several investigators have turned their attention to the subject, among whom may be mentioned Waldeyer, Beigel, De Sinéty, and Balfour. The researches of Beigel are especially interesting; for he shows most conclusively that the ova not only ripen in fœtal ovaries, but the follicles undergo retrogressive changes and form corpora lutea. I have examined systematically a very large number of fœtal ovaries, and am able to confirm the statement that the follicles enlarge, the ova ripen, and then undergo suppression. It must be borne in mind that few of these early ova are really shed into the peritoneal cavity, as occurs at and after puberty. The various changes are represented in Fig. 6. This ripening and suppression of ova is not confined to fœtal life or the period immediately succeeding birth; it goes on continuously, but at a diminished rate, from its commencement to puberty, as I have assured myself by examining ovaries of children at all ages between these two extremes. Ova shed in the interval between birth and puberty are not to be regarded as abortive, for there are instances, fortunately rare, in which girls have been impregnated at the age of ten.

FIG. 6.

Section of an ovary of a human fœtus at the ninth month. R F, Ovum in its follicle. C L, Corpus luteum. Cyst.

Having satisfied my mind beyond all doubt that this remarkable suppression of ova occurs in the human fœtus as a normal process and not an occasional event, I secured the ovary from the fœtuses of mammals as widely different as a monkey and a kangaroo, a lemur and a sloth, a Japanese deer and a cat. The species selected were the bonnet monkey (Macacus sinicus), the great kangaroo (Macropus major), the ring-tailed lemur (Lemur catta), and a deer (Cervus sika), besides other immature forms. In all these cases the ovaries exhibited follicles in every stage of development, growth, and suppression. If this process goes on in the ovaries of mammals as widely different as the species named in the above list, there can be little doubt that it is general throughout the mammalian series, and there are good reasons to believe that the process occurs in animals outside the mammalian circle. The only explanation to be offered concerning this phenomenon seems to be this: Mammals are to be regarded as derivatives from amphibian forms, which in their turn had a piscine ancestry. In order to maintain themselves in due proportion they must bring forth a large number of offspring, so as to guard against the wholesale destruction of their young by their natural enemies. The higher mammals are in a very large measure exempt from this danger, and the necessity for such extraordinary fecundity as the Ichthyopsida manifest is averted. Nevertheless, by virtue of the law of inheritance the ovary possesses an enormous number of ova. Although mammals are thus spared the trouble of bringing such large numbers of young into the world, the suppression of ova acts as an intrinsic source of danger,

Digitized by Google

for these unused follicles become in some instances the source of ovarian cysts, not in the human female only, but in the individual species throughout the subkingdom mammalia. It serves as an excellent instance of the application of evolution to pathology. Further evidence regarding the fecundity of the progenitors of the human species is furnished by organs other than the ovaries.

If I were asked by a student to furnish him with a single character, selected from the arterial system of mammals, which could be relied upon as a distinguishing feature in their anatomy, I should certainly choose the internal mammary and deep epigastric arteries. These remarkable vessels form a double line of communication situated on each side of the median line of the abdomen, and serve to connect the subclavian and iliac systems. The parallel offered by two main arterial stems coursing along the ventral aspect of the trunk seems to correspond so closely with the two main stems of the primitive aortæ that a morphological explanation of this character seemed irresistible. Prolonged medication and continued observation directed to this question have at length served to convince me that these arteries have some relation with the original disposition of the mammary glands. In man and many quadrumana among the higher Eutheria, and in Sirenia (manatee and dugong) among the lower, the mammæ are situated on the thorax. In the cow, mare, ass, and the like the mammæ occupy an inguinal position. The insectivorous Eutheria, as in so many other characters, hold an intermediate place in this respect, for the teats extend from the pectoral to the abdominal region. In the bats the mammæ may occupy, as in Pteropus, the axillæ; this is also the case in Galeopithecus; whilst in some lemurs these glands are placed on the arms. These last-mentioned situations are altogether exceptional; the most common regions are the pectoral, abdominal, and inguinal. These facts are suggestive of a primitive disposition of the mammary glands along the whole length of the ventral aspect of the trunk. If it be probable that this remarkable disposition of arteries is in any way related to the primitive arrangement of these glands, it would necessarily follow that in cases where the suppressed mammæ reappeared as supernumerary organs they ought most frequently to occur in relation with these vessels. This is exactly what happens. Supernumerary nipples and mammæ are by no means rare, for one observer, Dr. J. Mitchell Bruce, in a careful and valuable paper,[10] has considered sixty-five cases which came under his observation in three years. This observer informs us that out of 207 men examined in succession 9·11 per cent. presented a supernumerary nipple, and of 104 women 4·807 per cent. In the majority of cases the additional nipple was single, and without exception situated on the front of the trunk below and within the ordinary nipple, and more frequently on the left than on the right side. In more than one instance the anterior abdominal wall was the seat of the abnormality (Fig. 7). Until the appearance of Professor Leichtenstern's oft-quoted paper[11] supernumerary mammæ were believed to be extremely rare, and it is to this writer that the credit is due of exposing the fallacy. I am unaware of any observer who has personally examined sixty-five and eleven additional cases, except Dr. Mitchell Bruce; Leichtenstern's total was made up of thirteen cases noticed by himself and ninety-two recorded by others. These records clearly show that supernumerary nipples in nearly all cases follow closely the line of the internal mammary and deep epigastric arteries. The occurrence of nipples in male mammals is capable of easy explanation. Darwin was of this opinion: "If we suppose that during a former prolonged period male animals aided the females in nursing their offspring, and that afterwards from some cause (as from the production of a smaller number of young) the males ceased to give this aid, disuse of the organs during maturity would lead to their becoming inactive."[12] This view is very plausible and possible, but it is equally probable that, as every mammal at one period of embryonic life is hermaphroditic, the mammæ persist as remnants of that condition; in the same way the functional parovarian in the female represents the efferent ducts of the male gland. The fact that supernumerary mammæ occur twice as frequently in the male as in the female is to be accounted for on the principle of correlation. The female mammæ are functional, and require more blood-supply; this leads to dwarfing of the adjoining glands. The contrary of this pertains in the male. Our knowledge of accessory nipples and glands has been considerably increased since Darwin considered the matter, for, having regard to the very rare and in some instances questionable cases of supernumerary mammæ on the thigh and back, he thought that they weakened the probability of reversion. This did not prevent him ending the discussion in this way: "On the whole, we may well doubt if additional mammæ would ever have been developed in both sexes of mankind had not his early progenitors been provided with more than a single pair." No one can examine the evidence since accumulated without agreeing with this view; hence accessory mammæ must be regarded as atavistic structures in a true sense, and their occurrence is not confined to men, for they are not infrequently seen in other mammals, especially cows. The very valuable inquiry conducted by Dr. Champneys,[13] "On the Development of Mammary Functions by the Skin of Lying-in Women," adds a new interest to the matter, for it seems to prove that supernumerary mammæ without nipples may lie hidden under the skin of the axilla, and become active when stimulated by the increased function of the normal mammæ at the termination of pregnancy. Thus, the only conclusion one can arrive at from these facts is that the suppression of ova in fœtal ovaries and the very frequent occurrence of supernumerary mammæ and nipples are indicative of an ancestry from forms which not only produced a greater number of offspring, but in whom the males assisted in giving suck to the young.

It is impossible to reflect upon the preceding facts without feeling convinced of the truth of Bacon's remark: "No natural phenomenon can be studied in itself alone, but to be understood must be considered as it stands connected with all nature."

DISEASE IN THE PUNJAB.

BY SIR JOSEPH FAYRER, M.D., F.R.S., K.C.S.I.

IN the annual report on the sanitary administration of that part of Northern India included in the Government of the Punjab for 1885, there are facts recorded which it may be interesting to notice.

The population, according to the last census, is 17,514,978. The deaths from all causes among these were as follows:—

		Per 1000.
Cholera	1,936	0·10
Small-pox	7,575	0·40
Fevers	346,763	18·40
Bowel complaints...	17,711	0·94
Injuries	127,606	6·77
All causes	507,140	26·90

This return shows how relatively small a part cholera plays during some years in the mortality of the population, but how very grave and important a death cause is found in climatic fevers—a subject which stands much in need of further investigation.

There are two items among the death causes which are of special interest, and therefore worthy of attention. Under the head of injuries, which gives 127,606 deaths, there are recorded 852 from snake-bite, 146 from hydrophobia, and 17 from wild beasts—the latter item being small indeed compared with the same returns from other parts of India. The deaths from snake-bite are doubtless due to Naja tripudians, or the cobra; Bungarus cœruleus, or krait; and Echis carinata, or small (carpet) viper; and must, one supposes, be considered as inevitable, albeit it is difficult not to consider them as among those deaths which should be regarded as preventable. The hydrophobia cases, which

[12] Descent of Man. [13] Med.-Chir. Trans., vol. lxix., p. 419

Digitized by Google

seem to be on the increase, certainly suggest a similar idea; and also that here would be an excellent opportunity of testing Pasteur's method of treatment—a suggestion which may perchance be deemed not unworthy of adoption by some of our medical officers in the Punjab.

The following details are taken from the report cited; one of the last, it is to be feared, which will be drawn up by Brigade-Surgeon Bellew, C.S.I., whose retirement deprives India of one of her most distinguished sanitary officers:—

"The total deaths registered under the head of 'snake-bite' were 852, against 900 in the previous year. In the following districts the number of deaths due to snake-bite was larger than in the rest of the districts in the province: Lahore, 67; Mooltan, 61; Gujranwala, 58; Jhelum, 51; Muzaffargarh, 49; Kangra, 48; Thaug, 45; Montgomery, 42; Karnal, 41. It appears from the returns for the previous years that in these districts deaths from snake-bite are always more numerous than in the other parts of the province.

"The deaths from 'hydrophobia' have of late years very considerably increased, as will be seen from the subjoined table:—

1885	146	1881	139
1884	158	1880	107
1883	117	1879	69
1882	128		

Of the 146 deaths registered during the year under review, 20 occurred in Hoshiarpur, 19 in Lahore, 18 in Amritsar, 8 in Mooltan, 7 in each of the districts of Hissar, Ludhiana, Gurdaspur, Montgomery, and Sialkot.

"Five deaths were caused by scorpion sting—viz, 4 in Peshawar and 1 in Mooltan.

"The number of persons killed by wild beasts was as follows:—Carried away by wolves, 3; by jackals, 7; torn by a leopard, 1; by boar, 1; by bears, 3; killed by crocodiles, 2. There are comparatively few tigers in this part of India.

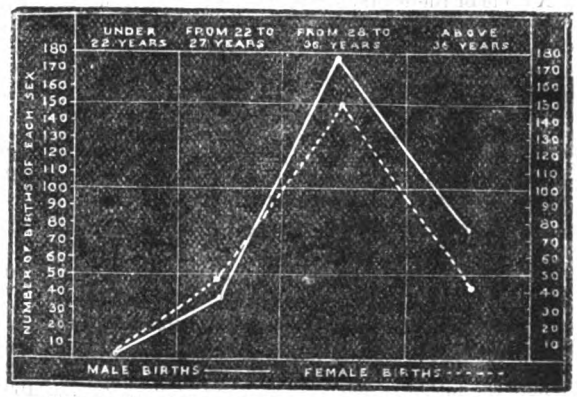
"The deaths registered under the head of 'other causes' were 127,604. Of this number 27,390 were due to chest diseases."

The above shows what an ample field exists for the study of disease in India, and what large opportunities our young medical officers may enjoy of prosecuting their studies in pathology, epidemiology, and hygiene in all its branches. The subject of fevers especially needs elucidation, and should be studied in a spirit of independence as regards preconceived notions of fever etiology.

Wimpole-street, W.

SOME CONSIDERATIONS IN REGARD TO THE CAUSATION OF SEX.

BY A. J. WALL, M.D. LOND.,
H.M. INDIAN ARMY.



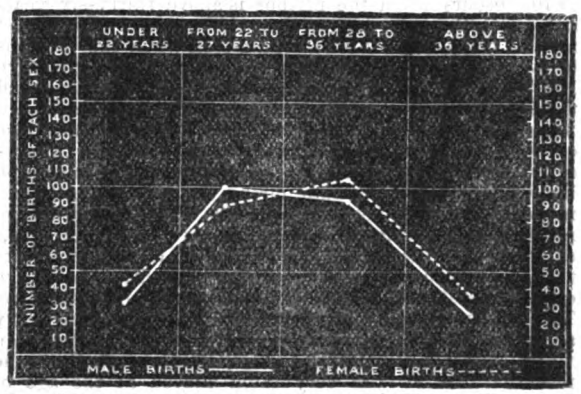
(Concluded from page 263.)

IN the cases of the fathers and mothers that have been taken it will be observed that each has been treated without reference to the other. The influence of the age of the mother has been considered without regarding the age of the father, and *vice versâ*. But though this is so, yet, as these were families whose parents married under the ordinary conditions and rules of society, it is clear that a very large proportion of the fathers were a few years older than the mother, and therefore these families must have a preponderating influence. In fact, in these statistics the age of the father was on the average 6·6 years greater than that of the mother in the whole 1200 families. But if we take the proportions obtained from all these families and contrast them with those we shall obtain by selecting families in which wide differences existed between the ages of the fathers and mothers, we shall then be in a position to see what results are due to these great differences of age.

There are in these tables 111 families in which the father was considerably younger than the mother, the differences being from nine months to ten years. In these families there were 546 children, 297 males and 249 females, or 119·2 males to 100 females, being a great excess of males over the mean proportion of 107·4 to 100. If we divide these births into periods according to the age of the mothers we obtain the following results:—In the period of immaturity only two children were born, one of each sex, showing that when the father is younger than the mother, the mother as a rule marries somewhat late in life. In the period from twenty-two to twenty-eight years there were 86 births, 39 males and 47 females, or only 82·9 males to 100 females, against 98·3 males to 100 females, which was the proportion for the whole of the families, showing again how incapable the immature male is of imprinting his sex on the offspring when the female is at her prime. From the twenty-eighth to the thirty-sixth year inclusive of the mother, 179 males

CHART 3.

Ages of Mothers.



Showing the number of male and female births at different periods of the ages of the mothers in families in which the father was younger than the mother.

were born to 156 females, or 114·7 males to 100 females, or an excess of male births over the 111·6 males to 100 females occurring in all families taken together; whereas in the last period of decline of the power of the mother there were 78 males to only 45 females, or 173·3 males to 100 females, an enormous excess of males over the proportion obtained for this period at all ages of 114·2 males to 100 females. Chart 3 shows those varying proportions.

Now let us contrast this with a series of families as widely different as possible—that is, where the father is much older than the mother. In 111 fertile families in these tables the

CHART 4.

Ages of Mothers.

Showing the number of male and female births at different periods of the ages of the mothers in families in which the father was more than fifteen years older than the mother.

father was older than the mother by more than fifteen years, the excess varying from fifteen years to forty-nine years. In these families there were 519 children, 255 being males and 264 being females, or only 96·5 males to 100 females, being actually an excess of females at all the ages of the mother taken together. During the period of immaturity of the mother there were 34 males born to 39 females, or 87 males to 100 females, or an excess of females. In the period from twenty-two to twenty-seven years 100 males were born to 91 females, or 109·8 males to 100 females, or an

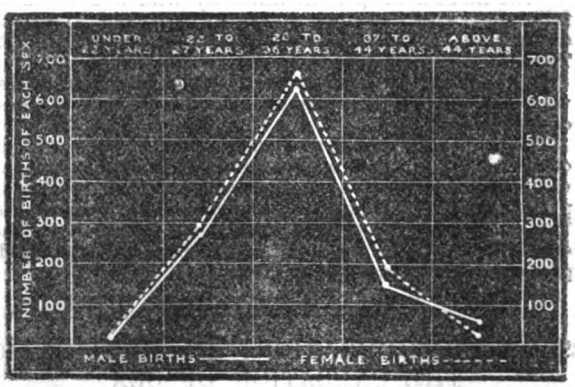
Digitized by Google

excess of males. From twenty-eight to thirty-six years inclusive, 97 males were born to 103 females, or only 94 males to 100 females; whereas in the last, or declining period of life 24 males were born to 31 females, or only 77·4 males to 100 females, contrasting markedly with the proportion of 114·2 males to 100 females obtained for this period from families at all ages of the fathers, and still more strongly with the proportion of 173·3 males to 100 females obtained for the same period in families where the father was younger than the mother. Chart 4 shows the results obtained from these families, and, as it is drawn on the same scale as Chart 3, it illustrates also the relative fertility of these families, differing only in the age of the father, and shows how comparatively infertile families are when the father is aged.

A table of these varying results will enable us better to study the relation between these differences.

NUMBER OF MALES BORN TO 100 FEMALES UNDER VARYING CIRCUMSTANCES AS TO THE AGE OF THE PARENTS.

A. *At all ages of the mothers.*	
All births	107·4
Where the father is younger than the mother	119·2
Where the father is much older than the mother ...	96·5
B. *Mothers below twenty-two years of age.*	
All births in this period	114·9
Where the father is younger than the mother	100·0
Where the father is much older than the mother ...	87·0
C. *Mothers from twenty-two to twenty-seven years.*	
All births at this period	98·3
Where the father is younger than the mother	82·9
Where the father is much older than the mother ...	109·8
D. *Mothers from twenty-eight to thirty-six years.*	
All births at this period	111·6
Where the father is younger than the mother	114·7
Where the father is much older than the mother ...	94·0
E. *Mothers above thirty-six years.*	
All births at this period	114·2
Where the father is younger than the mother	173·3
Where the father is much older than the mother ...	77·4
F. *At varying ages of the fathers.*	
Where the fathers are below twenty-two years of age	71·0
Fathers between twenty-two and thirty-six years ...	109·5
Fathers from thirty-seven to forty-eight years ...	107·1
Fathers above forty-eight years	92·4



These figures speak for the most part sufficiently clearly for themselves. Thus the highest rate of male births (173·3 to 100) occurs when the mother is above thirty-six years and the father is younger than the mother. The lowest rate of male births (71 to 100) is seen when the father is below twenty-two years of age, and the next lowest (77·4 to 100) when the mother is above thirty-six years of age and the father is more than fifteen years older than the mother. A great excess of females (82·9 males to 100 females) also occurs when the mother is between twenty-two and twenty-seven years and the father is younger. It has long been known that in illegitimate births the females are more numerous than in legitimate births, and Darwin, whose notice nothing seemed to escape, in his "Descent of Man," suggests that the excess may be due to the want of care that these mothers experience during parturition, leading to excessive deaths amongst the males from their greater size. This table renders it probable that the excess may be partly accounted for by the mother being frequently at the age in which excess of females is to be expected, and partly to the fact that the male is very often indeed at the age of immaturity, an explanation to a certain extent to the credit of humanity.

But there is one portion of this table that requires notice. In all the births between twenty-two and twenty-seven years of age of the mother, the male birth-rate is 98·3 to 100 females. But when the father is younger than the mother, the male birth-rate sinks to 82·9 males to 100 females; whereas when at the same age of the mother the father is more than fifteen years older than the mother, the male birth-rate, instead of sinking further, rises to 109·8 males, contrary to all expectation. We must therefore submit the 2275 births taking place at this period of the mother's age to a more minute analysis, to which they are well entitled, as they represent nearly one-third of the entire number of births.

In the first place, the greatest proportion of female births obtains in the twenty-second and twenty-third years of the mother's age, when the proportion is 87·9 males to 100 females. In regard to the age of the father, the greatest proportion of male births for this period of the mother's age is when the father is between twenty-two and twenty-seven years. When at this period of twenty-two and twenty-seven years of the mother's age the father is younger than the mother, but only by a few months, there are only 78·3 males born to 100 females; but when the father and mother are as nearly as possible equal in age, the difference not exceeding six months either way, the proportion of males rises to 145·7 to 100 females. But when the father is older than the mother, but neither of them exceeding twenty-seven years, the male birth-rate drops to 96·2 to 100 females. Thus, we see that when the father and mother are both at their prime, the influence of the male parent in imprinting sex on the offspring is stronger than that of the mother; but let the father be even a little beyond the prime, or a little below it, and the mother is far more powerful. When the father is between twenty-eight and thirty-six years, the mother's age still being between twenty-two and twenty-seven, the birth-rate is 98·7 males to 100 females; and when the father's age rises to between thirty-seven and forty-eight years, the male birth-rate drops to 95·4 to 100 females. But after this a great change occurs, for when the father is older than forty-eight, the male birth-rate, instead of dropping further, rises to 133·3 to 100 females. Is this totally unexpected rise due merely to smallness of

CHART 5.

Ages of Fathers.

Showing the number of male and female births taking place when the mothers are between twenty-two and twenty-seven years at different ages of the fathers.

numbers, or to a real preponderance of male births under these circumstances? If we increase the number by taking all births after the father has reached forty-five years, the age of the mother remaining between twenty-two and twenty-seven, we get an increased proportion of males—viz., 138·7 males to 100 females. So also when the mother is below twenty-two and the father is above forty-five the proportion is 175 males to 100 females. It seems, therefore, in the highest degree probable that when the mother is under twenty-eight and the father is very much older a considerable excess of male births occurs. This agrees with what I have observed in private families, and historical evidence points the same way: the cases of Louis XIII., our Edward VI., the offspring of both the Napoleons, and many others will occur to every reader. *The explanation may be too obvious to require mention here;* but I do not think this. It certainly cannot be due to the father having increased sexual power in his declining years, for when the father is above forty-eight, but the mother is between twenty-eight and thirty-six years, only 88·8 males are born to 100 females. It will be far more reasonable to attribute it to the very modified sexual feeling elicited in the female when the male is "out of all reasonable match," as Touchstone says, which may produce an actual inhibitory effect on the nerves of the generative system. If this be so, it would throw an additional light on the reason why in illegitimate births there should be an increased number of females, as these conditions are there reversed. Chart 5 shows the number of

Digitized by Google

male and female births taking place when the mothers are between twenty-two and twenty-seven years at the different ages of the fathers.

The results obtained may be briefly summed up by saying that each parent while in his or her prime has the greatest power of imprinting his or her sex on the offspring. That probably the male is the most potent when the age is exactly equal. That the immature parent has very little power of doing so, the immature male being peculiarly powerless, for of all births when the fathers were below twenty-two, the proportion of male births was only 71 to 100 females. That when there is a difference in the age of the parents the sex of the offspring is most frequently that of the parent who is nearest the prime of life; but that if the male should be much older than the female, the female being in her prime, a considerable excess of male births may be expected. Thus, males are obtained with the greatest amount of certainty with females above thirty-six years of age and males distinctly younger, and the same result is obtained with old males and disproportionately young females, and also with immature females. Whereas females are greatly in excess if we take males under twenty-two years of age and females above that age, or else males above fifty-six years of age with females about fifteen years or twenty years younger.

It may be stated in addition, as a by-product of these inquiries, that in England the peers, of whom a fair proportion marry in their prime have a considerable excess of male children. The average age at marriage of fifty peers, or eldest sons of peers, that had offspring was thirty years; not one was below twenty-one years, and thirty-two were above twenty-five years. The lowest classes in England, who exercise about as much forethought in their domestic arrangements as dogs, have also apparently an excess of males. Of fifty fertile marriages of this class taken indiscriminately, the dates being verified as far as possible, twenty-three husbands were below twenty-one years of age, and only six were above twenty-five, the average age on marriage being twenty-two; the whole of the families, it is scarcely necessary to add, were in receipt of charitable relief. In the middle classes there appears to be an increased proportion of female births through the later marriage of the males. In England, with the exception of 1884, the proportion of male births, as might be expected, has been falling for many years. The cause of the rise in that year, which may not be continued, is far too obscure a subject to be speculated on here.

In regard to the exact cause of sex, the evidence here adduced is very unfavourable to the view that it depends merely upon the number of spermatozoa that penetrate the ovum. For we see that men at advanced age are even more capable than very young men of producing males. And, again, females in their prime give an excess of females with males somewhat older, but males are more common when the father is greatly older. Not to discuss the question minutely, it would seem that the vigour of the embryo-forming tissue is a more important agent than its quantity, and that this may be modified in various ways, the female element being especially liable to modification. There are not wanting, for instance, cases in the tables that seem to imply that anything that debilitates a parent renders it far less capable of imprinting its sex on the offspring. These, however, are points quite beside the present question, which is the influence of the age of the parents. But enough has been said in this relation to prove how important a factor this is, for it can change a mean proportional birth-rate of 107·4 males to 100 females, on the one hand, to 71 males to 100 females, and, on the other, to no less than 173·3.

FRENCH HOSPITAL AND DISPENSARY.—The nineteenth annual dinner in aid of the funds of this charity took place on the 5th inst., Comte d'Aubigny in the chair. Opened in 1867 and enlarged in 1878, it has afforded relief to 4386 in-patients and to 100,175 out-patients, drawn from 24 nationalities, so that, although French in name, the charity is cosmopolitan in character. During the evening subscriptions amounting to about £2000 were announced.

THE governors of the Bedford Infirmary having determined to purchase the fields contiguous to the building from the Duke of Bedford's trustees for £3350, an intimation has been received from his Grace of his intention to contribute £1000 towards the purchase-money, and a like donation has been promised by Mr. Whitbread, M.P.

MINIMA VISIBILIA AND SENSORY CIRCLES.

BY THE LATE BRIGADE SURGEON T. OUGHTON,
ARMY MEDICAL DEPARTMENT.

HARRIS found that a black square on a white card, the side measuring $\frac{1}{70}$ in., is distinguishable as a mere speck at the distance of 40 ft. from an emmetropic eye, whilst the square is not perfectly defined in colour at a further distance than 7 ft.; he found also that these distances corresponded to visual angles of 44″ and 4′5″ respectively. Ernst Weber 's experiments on the skin elaborate a result that a circular metallic tube, the diameter measuring $\frac{1}{2}$ in., is felt as a single point when pressed against the palm of the hand, whilst its shape may be perceived with its diameter exceeding $\frac{1}{2}$ in. (sensory circle of the palm). Hence two varieties of minimal perception may be recognised—viz., points and areas (minimum visibile vel tactile et punctorum et extensionum vel formarum). Our present subject will deal with the proposition that all minima are of a secondary nature, defining and being defined by a limitation in the acuity of muscle-perception. That there is such a limitation in the apperception of visual angles is exemplified in the judgment of apparent distance being liable to error in the retina of actual objective distance, as well as in apparent relievo being less marked in a like ratio (minimum motorium). One strong argument consists in bracketing together the non-existence of minima auditoria vel objectoria with the absence of suitable motorial appendages to these senses; so by analogy physiology would probably supply no basis for dogmas on the present subject were there wanting the groundwork of a visual or tactile muscular diagnosis. Then, again, the phenomena of minima visibilia and sensory circles are so harmonious in two very diverse sensations that nothing short of a common causation can adequately solve the harmony; neither are discrepancies in these phenomena, where any exist, explicable on terms other than those of the proposition under consideration. Finally, by coupling the facts that visual angles are of muscular origin, whilst the minima of vision have been resolved into such angles by Harris ("Treatise on Vision"), the proposition as regards vision seems to be adequately verified.

Let us examine a series of ascertained data so as to institute a comparison between their solution by the hitherto prevalent and the present doctrine, simply premising that the former tenet has been constructed on the view that all sentient points exercise their directional and positional powers by an inherent faculty of primary sense—thus: "The skin is the criterion of locality" (Todd and Bowman). ..... "The simple sense-impressions of the optic nerve are colour, intensity, and direction" (Le Conte). As regards the skin, there is no cutaneous point that we can prick without producing pain; as regards the retina, a star is distinctly visible and without apparent magnitude, even though it be magnified 5000 diameters. From these data we are committed, by the former dogma, to a conclusion that each minimum punctorum corresponds with the brain by a distinct and duly insulated nerve-fibril. Dr. Young has calculated that 10,000,000 of nerve-fibrillæ pass through the contracted orifice of the sclerotic tissue, and as many are possibly transmitted by each sensory nerve. Now, such a minute subdivision into nervelets is entirely superfluous, according to our proposition. To all intents and purposes, both skin and retina may be regarded as sentient expansions or superficies, whose every minimal point is subject to a muscular surveillance. This conclusion seems to be warranted by any limit to the minuteness of visibility, with sufficient luminous intensity, having been disputed by some metaphysicians; and, additionally, by stars of the smallest magnitude being seen under the comparatively greater visual angle of 44″, whilst the smallest tactile impression is referred to the entire area of its correspondent sensory circle, equalling in apparent size the impact of numerous sentient impressions on the same area. It has been surmised, with a view of covering these peculiarities, that each visual minimum of 44″ corresponds to a single cone of the bacillar layer, so that an identical excitation is effected by the incidence of purer or more luminous raylets; but a serious objection consists in the surmise being inapplicable to the case of sensory circles—namely, that their numerous ultimate fibrils coalesce into a single sensory fibre. For, granting

Digitized by Google

this to be so, two cutaneous points in adjacent sensory circles of ½ in. diameter would be apparently duplicate with an interval between them of only ½ in., which is not the case. Sensory circles, therefore, are mere metaphysical abstractions in the above respect, and the inextricable blending or interlacement of their impressions points only to a common muscular influence.

Then, each retinal cone must be subdivided into at least three terminal fibrils in order to explain intelligibly the perception of colours (Young, Helmholtz, &c.); there must be a blue, yellow, and red, or a red, green, and violet fibril (primary colours), whilst the function of the entire cone naturally combines these minimal colours for a sensation of minimal whiteness. I must protest against the coinage of a minute anatomy in this perfunctory manner; both matter and organisation are pliable commodities, but I think hypothesis must be stretched here. Quite sufficient difference exists in the intrinsic nature of coloured lights to explain adequately a variety of correspondent coloured perceptions without resorting to variations in nervous mechanism; neither should it be forgotten that the province of nerve organisation is to interpret rather than to modify nature, for of a truth (others notwithstanding) there is a latency in the cerebral constitution of every natural imponderable that may be transmitted thereto by natural channels. Far be it from me, nevertheless, to deny that the minimum visibile of 44″ is much concerned in the several phenomena of colouration, colour-blindness, &c. And, apart from colouration, transparencies teach us thus much about their construction—that their molecular particles fall extremely short of the minimum visibile.

Based on the evidence of apparent extension (minimum formarum) is the doctrine of the cerebral realisation of sensational points, indicating a similar mechanical deportment of nervous structures. Impressions on two adjoining minimal areas, retinal or cutaneous, give rise to the mental impression of contact, and the excitation of several contiguous areas effects an idea of coherence or extension; such experiences could not obtain, according to the above dogma, excepting on the inference that the termination of afferent fibrillæ in the brain is a precise facsimile of their origin. Bernstein says, "The representation of the surface of the body is imprinted upon our brain," so that by experience or practice (which may signify a constant repetition of primary perceptions) the brain is capable of determining any points of the skin's surface that may be touched.[1] Professor R. S. Wyld writes: "In vision there is mapped out in the sensorium a true representation, though on a different scale, of the forms, motions, and relative sizes of external objects as they exist on the retina"; [2] and he has submitted a diagram, explanatory of single and double vision, in which each retinal image is actually reproduced in the corpus quadrigeminum.[3] But, on the contrary, the idea (perception) of space or extension is as different from that of body (the sense of contact) as it is from that of a scarlet colour; it is true that a scarlet colour, like body, must have extension, but the two ideas are distinct (Locke). Moreover, since the idea of solid form (relievo) is contained by surfaces, and has been proved to be a secondary perception elsewhere, the idea of superficial extension must also be of a secondary nature. Wherefore the present proposition renders the anatomical identity of relation between the proximal and distal extremities of an afferent nerve another redundant additamentum to minute anatomy.

Nevertheless, in further elucidation of the subject, the contiguity of sentient impressions on peripheral nervous expansions is clearly a *sine quâ non* in the constitution of an idea of extension; retinal images or sensory impressions must be arranged *in ordine* for the generation of the mental idea of coherence, although we deny their reception *in ordine* by the brain through the channels of primary perception. This will be obvious on reflection that the directional influence of a voluntary muscle upon neighbouring impressional areas varies by a regulated increment, according to their regular positional relation to the dynamic centre of secondary perception. It is maintained that all ideas of extension, whether definite or infinite, may be ultimately resolved into the appreciated movements occurring in exarthrodial and diarthrodial articulations in the tactile sense, or into unfettered ocular rotations in the case of vision; and, further, the coherence of extension is comprehended ultimately by a duly perceived aggregation of what we may designate a minima motoria.

(To be concluded.)

ABDOMINAL SECTION FOR PELVIC SUPPURATION.

BY WM. ALEX. MACKAY, M.B., C.M.

INES D——, aged twenty-four years, gives the following history. She has been married for four years and a half, and has given birth to three children. Two days after the birth of her last child she felt a severe pain in the region of the left ovary. Since then—that is, during the last six months—she has never been free from pain and feverishness. The menses have been completely suppressed throughout her illness; no treatment has given any relief; she has been losing flesh rapidly, and feels weaker every day.

When seen the patient presented a most emaciated appearance. On examination, a hard tumour fixed and painful to the touch, could be felt in the left iliac region, filling it up and extending nearly to the middle line forward, and up to the umbilicus. Per vaginam, a rounded mass, painful to the touch, was felt to the left of the uterus, and extending round behind it. Womb fixed; cervix hard. Bimanually, indistinct fluctuation was felt in the tumour, but there was no indication of its pointing anywhere. The patient bore this examination very badly, and was very hopeless of her condition. She was put on extract of malt and allowed to rest for a week, as she had come a long diligence journey. During the week her temperature was always above normal, and her pulse between 110 and 120. Urine free from albumen and normal in quantity. Heart and other organs healthy. Motions fairly regular, and presenting nothing of note.

A second examination of the tumour revealed nothing new, and on April 29th, 1884, the following operation was performed. I opened the abdomen in the middle line, beginning about midway between the umbilicus and the pubes; the incision was carried down two inches. On opening the peritoneum, the index-finger came immediately upon the uterus and roof of the pelvis, which was raised up so as to lie against the anterior abdominal wall, but was not adherent. The uterus was quite immovable, and fixed to a large swelling, which lay behind it and surrounded its left side. Deep fluctuation could be felt at a point about an inch behind and half an inch to the left of the left cornu of the uterus. The incision was enlarged upwards to get at this point, which with the whole pelvic roof was raised to within an inch of the umbilicus. With considerable difficulty a Wells' trocar was here pushed into the tumour, a sponge having been first placed immediately behind the intended opening. About fourteen ounces of pale-yellow pus immediately ran out through the tube. On withdrawing the trocar, a little blood and pus followed, and was caught up by the sponge. On introducing the index finger into the abscess cavity, it became apparent that the trocar had traversed quite one inch and a half of indurated tissue before it entered the cavity. After clearing away the blood and cleansing the abdomen with warm sponges, the opening into the abscess was secured by a continuous suture to the abdominal wall at the upper part of the incision. This was the most difficult part of the operation. It was a belaying down of the abdominal wall to the wall of the abscess, the latter being immovable. The rest of the abdominal incision being closed with silk sutures, a drainage-tube was passed into the abscess cavity and an iodoform dressing applied, with strips of plaster and a flannel binder. The anæsthetic employed was a mixture of chloroform and ether. A good deal of vomiting followed the operation, lasting till the evening of the next day.

April 30th: Temperature normal; pulse 104. Wound dressed. Ordered a little brandy in warm water for vomiting. —May 1st: Temperature normal; pulse 88. Had a good motion. Complains of slight pain throughout the abdomen. Wound dressed.—2nd: Temperature normal; pulse 90. Wound dressed. Discharge passes freely into the dressings around the tube.—3rd: Temperature normal; pulse 114. Patient feels very well, and has a good appetite. Wound dressed. Pus of a dark-red colour.—4th: Temperature

Digitized by Google

normal; pulse 100. Wound dressed. Pus smelling peculiarly.—5th: Temperature normal; pulse 100. Wound dressed. It is now evident that there is a communication between the intestine and the abscess cavity, as the discharge is mixed with fæces.—6th: Temperature normal; pulse 112. Patient excited and frightened, because she has felt while straining at stool that a good deal of fæcal matter comes by a tube and none by the anus. Wound dressed.—7th: Temperature 99·5°; pulse 114. The patient feels very well, and is not alarmed, as she has passed three motions by the anus and very little by the wound. Since the first passage of the fæcal matter by the tube the abdominal wound is carefully protected by an arrangement of mackintosh and adhesive plaster, and the attendant constantly renews the dressing around the mouth of the tube; also the abscess cavity is frequently syringed out with carbolic lotion.—12th: Temperature and pulse normal. Wound dressed; almost no discharge. Continuous suture removed. The abdominal incision is firmly healed. The patient eats and sleeps well.—21st: Drainage-tube removed. Cavity quite contracted. Patient sitting up in bed.

The woman went home restored to health on May 31st. Menstruation returned at the end of July and continued regular. A year after the operation I was told that the patient continued to enjoy perfect health.

Remarks.—That this case is an example of suppurating hæmatoma I think there can be little doubt; but a special interest is added by the communication, which occurred on the fourth day after operation, between the bowel and the abscess cavity. It is probable that we have here an illustration of the course of such abscesses as described by Dr. West, who says: "When suppuration takes place, the matter makes its way outwardly through the vagina or through the intestinal canal in almost all cases in which the inflammation is limited to the parts contained within the broad ligament." From the length of the illness, which lasted six months, it seems probable that the pus had begun to seek an outlet towards the bowel. On evacuating the abscess, the weakened part of the intestinal wall would yield towards the cavity, and finally give way when the patient strained at stool. No pus was at any time observed in the motions. The rapid progress toward complete recovery did not appear to be delayed by the complication which occurred.

Huelva, Spain.

CYST OF THE GREAT OMENTUM.

REMOVAL, RECOVERY.

BY J. C. GOODING, M.D.

MISS ——, in 1878, when aged eighteen years, first noticed a lump the size of a hen's egg low down in the right iliac region, which, at the monthly periods chiefly, was painful. It gradually enlarged upwards till, at the time of my first visit in August, 1879, it had attained the size of a cocoa-nut and reached two inches above and to the left of the umbilicus, and three inches below, extending back into the lumbar region. It was elastic, could be completely pushed across the abdomen to the left of the umbilicus, and pressed down to Poupart's ligament; there was most limitation to upward movement, and between it and the liver there was resonance. My first impression was that it was a renal growth, but the tumour could be moved away from the kidney without leaving any sense of void in the loin; it was freely movable in all directions, but less so from the ovarian site. The urine was healthy, and there was no constitutional disturbance. I diagnosed ovarian cyst with long pedicle. In March, 1880, the patient at my request saw Sir S. Wells, who wrote me that his impression was it was renal, but, having doubt, wished Sir W. Jenner to see the case with him, which he did a few days afterwards. The result of the consultation was that they both, "while doubting, inclined rather to the view of an ovarian tumour with a long pedicle than a renal cyst or tumour," and both agreed in advising, "in the absence of any urgent symptoms, no surgical interference."

During the summer of 1881 the patient began to suffer from sickness and occasional vomiting after meals, and a great deal of shooting and aching pain in and about the tumour. These symptoms much impaired her health; and interference, for which the patient was anxious, was determined on. The growth had now attained the size of a child's head of four years old, had equally enlarged without altering its relation to other parts, was as mobile as ever, and obviously contained fluid.

On April 27th, 1882, Mr. Cardew gave ether and Mr. C. J. Newton assisted me. When the patient was anæsthetised the tumour retreated so much under the hypochondrium that it was obviously not ovarian (a confirmation of the value of anæsthetics for abdominal diagnosis—so well known, but so seldom employed), a short incision into the peritoneal cavity, confirming this, was extended to the umbilicus, and disclosed a white cyst covered by peritoneum; this was scratched through so as to admit the finger, which was swept round, breaking down strong areolar tissue. On seizing the tumour with a vulsellum a clear fluid gushed out; then a most tedious process of separation, facilitated by holding the thin-walled cyst up against the light, was effected by scratching through dense cellular tissue, its closely fitting envelope. There was no pedicle, the tumour was embedded in folds of the omentum, having the transverse colon immediately below it. There was no hæmorrhage. The entire operation was conducted under carbolic acid spray—a practice, however, which I no longer follow.

The patient, very pallid and cold, but with fair pulse (60), was removed to bed, and after a couple of hours the extremities became warm. During the first night there was much pain referred to the left shoulder and back. For thirty-six hours there was continuous sickness. On the second day the temperature was 100° and the pulse 98-104. Barley-water and milk in small quantity were relished and retained. On the third day the temperature was natural, and the pulse 92. On the seventh day three sutures were removed, and the remainder on the tenth day; firm union had taken place. The progress to recovery continued uninterrupted, and the patient when last seen (September, 1883) was enjoying good health.

The tumour much resembled an hydatid cyst, but it was not of this nature. Its origin (obscure) might have been due to a severe blow in the abdomen sustained some months before.

ST. MARY'S HOSPITAL.

PARTIAL ENTEROCELE; GANGRENE; RECOVERY; REMARKS.

(Under the care of Mr. EDMUND OWEN.)

THE term here used to describe the hernia which was the cause of the symptoms in the following case is one which will probably find general acceptance. If our readers will refer to the report of the meetings at which the papers referred to (*vide infra* and page 314) were discussed, they will gain much information on the subject of this form of protrusion.

On November 30th, 1886, a spare man, aged fifty-seven years, was admitted with a strangulated femoral hernia on the left side, of the size of a large walnut. He vomited a good deal, but the ejecta had no stercoraceous odour; there was no tympanites and no hiccough, but the man was somewhat collapsed. He said that the hernia had been down generally during the past three winters, when his cough was bad, but that nearly the whole of it went away when the mild weather arrived; that there was, however, at the best of times, always a very small piece which did not go back. He said further that the hernia, in the larger mass, had been down for nearly a week, that for five days his bowels had not acted, and during that time he had been frequently sick, and in pain across the umbilicus. Without any difficulty Mr. Lloyd, the house-surgeon, returned the

Digitized by Google

chief part of the protrusion, and then applied an ice-bag to the small piece which resisted his efforts.

Mr. Owen saw the patient some hours after his admission, and finding him free of pain and nausea, and learning that the general improvement, which set in directly after the partial reduction of the hernia, was as real as it was apparent, he decided not to cut down upon the irreducible piece, which he took to be a nodule of omentum. That decision was justified; all went well; the bowels acted nearly every day; but still the small piece remained irreducible. On the tenth day in hospital the hernia began to pain, and the ice was entirely left off; and a week later an abscess was incised over the seat of the hernia, pus and fæces escaping. After this the local pain entirely passed away, but for some weeks a fæcal fistula kept on discharging. The opening eventually closed; the remnant of the hernia has disappeared, and the man is quite well, at any rate so far as his groin is concerned.

Littre gave various important indications for recognising strangulation of a diverticulum, or of a piece of the side of the intestine, all of which are illustrated in the case just recorded. Thus: The bowels continued to act during the progress of the attack, because the channel itself was not obstructed. The bowels were confined whilst the supplemental hernia was strangulated, but they began again to act directly that part was released, although the diverticulum, or the small piece of the side of the bowel, remained so tightly strangulated that it sloughed. The man had no hiccough or abdominal distension, nor did he vomit except on one occasion—that was before the chief mass was reduced. The permanent prolapse was particularly small, and, though it was persistently and tightly pinched, the general and local symptoms ran an unusually mild course.

The small irreducible part of this strangulated hernia was, without doubt, intestinal, for on the occurrence of gangrene and abscess fæces escaped when the tumour was incised. That the strangulation did not implicate the entire circumference of the intestine is evidenced by the fact that from the very day that the chief part of the strangulated mass was returned the bowels began again, and continued, to act naturally. Possibly the piece of bowel which sloughed was Meckel's diverticulum, or an adventitious diverticulum; possibly it was a piece of the side of the bowel. But that this particular feature in the case remained obscure is probably much to the advantage of the man himself. Mr. Owen said he was not of opinion that a clinical history is complete only when a necropsy is detailed.

On April 19th, 1886, Mr. Morgan read a paper on a case of strangulated hernia without complete obstruction of the bowel before the Medical Society of London,[1] and on December 14th last Mr. Treves chose the same subject for a communication to the Medico-Chirurgical Society,[2] and on each occasion reference was made to an essay which was read by Littre in 1700 at the Académie Royale des Sciences, in which the author described a fatal case of hernia which was probably strangulation of Meckel's diverticulum. By Littre's hernia, however, one now generally understands a partial hernia of the circumference of the bowel rather than of a diverticulum. But on this matter opinions differ; and with some surgeons the name of Richter is usually associated with that condition, Littre's name being connected with diverticular protrusions. Thus what should be a tolerably simple subject has become overburdened with proper names, and terminology has become indefinite. Mr. Owen ventured to express the opinion, therefore that in the interest of surgical literature in general, and of the student in particular, it is expedient that individual names be not associated with special kinds of hernia. The surgical archæologist may dissent from this proposition, but specialism in any branch of knowledge should tend always to simplification. Indeed, in the discussion of one of the excellent papers just referred to, Mr. Hulke is reported[3] as saying that he rather thought that Richter himself did not fully comprehend the matter with which his name is so honourably mentioned. Every surgical reader, however, can understand what is meant by a "lateral hernia of the bowel," and by a "hernia of a diverticulum." The former term, therefore, or the still more comprehensive one, "partial enterocele," is preferred by Mr. Owen as the heading to this report.

NEWCASTLE-ON-TYNE INFIRMARY.

HERNIA OF OVARY.

(Under the care of Dr. OLIVER.)

A WELL-DEVELOPED young girl, aged sixteen, a housemaid, was brought to the infirmary complaining of a painful swelling in the right groin. Ten days previously to this, when lifting a heavy pan, she felt something crack in the lower part of her abdomen. This was followed by a feeling of sickness, but she did not vomit. The bowels had been opened daily since the commencement of the illness. On examination, a tender, roundish swelling was found in the neighbourhood of Poupart's ligament on the right side, which was easily reduced. Three days after this, as the swelling had reappeared, she returned to the infirmary, having vomited a good deal. Walking was to her now a matter of great pain. She said that she suffered most pain when she lay on her left side, less when she lay on her right, but least of all when on her back. The swelling, which was about the size of a walnut, lay immediately under Poupart's ligament (right); it was soft, elastic, of firm consistence, and did not give one altogether the feeling of being intestine. It had been easily reduced in the first instance, but on now handling the swelling special notice was taken of the amount of pain which it caused, the sense of sickness complained of, the extreme pallor of the face, and the tendency to faintness. No impulse was detected in the swelling on coughing, nor in its reduction was there felt anything like a slip or a gurgle. It was regarded as a hernia of the ovary. On examination under chloroform, an ill-defined mass could be felt behind Poupart's ligament (right), which, on being displaced, fell into the pelvis to the right of the uterus. The uterus itself felt healthy, but to the right of it lay a round smooth mass about the size of a walnut freely movable, easily displaced in front of the uterus, and easily tilted upwards by and beyond the reach of the finger. A coil-like structure could be felt lying external to this smooth round mass as it lay in the pelvis, but whether it was a distended Fallopian tube or a portion of small intestine, it was impossible to say. The round mass was doubtless the right ovary. On the left side the ovary was felt to be about a quarter of the size of that on the right, while its Fallopian tube could be felt about the size of a quill. On one occasion after this, when the swelling reappeared in the groin, the ovary had evidently dragged down with it a portion of intestine, for in the reduction a gurgle was distinctly felt. The diagnostic signs of hernia of the ovary relied upon were—the dragging and pain felt by the patient when she lay on her left side, the side opposite the swelling; pain on movement of the limbs; pain of a sickening character on manipulation of the swelling; pallor of the countenance and tendency to faintness; the consistence of the swelling; and, in its reduction, absence of slip and gurgle. The house-physician, Mr. Waldy, had a proper truss made for the patient, since wearing which the displaced right ovary, still in all probability enlarged and prolapsed, has ceased to trouble her.

DUNDEE ROYAL INFIRMARY.

ACUTE SPORADIC CEREBRO-SPINAL MENINGITIS; DEATH ON THE FOURTH DAY; NECROPSY; REMARKS.

(Under the care of Dr. SINCLAIR.)

FOR the clinical record of the following case we are indebted to Mr. H. Hampden Pridie, house-surgeon; and for the notes of the necropsy to Mr. A. M. Stalker, pathologist to the infirmary.

Jessie P——, aged twenty-one, mill-worker, was admitted on the afternoon of August 14th, 1886, having been certified as suffering from typhus. There had been no typhus, however, in her neighbourhood for a long time, and there was no evidence obtained either on admission or subsequently of contact with typhus. Three days before admission, without any apparent cause in the shape of injury, overfatigue, or exposure to excessive heat, she had a rigor, followed soon after by great heat, loss of appetite, excessive vomiting, severe headache, and noisy delirium.

On admission the patient was very drowsy, and had a dusky aspect and flushed forehead. Pulse 124, bounding; respiration 28; temperature 101·4°. Tongue furred and

Digitized by Google

beginning to dry. Spleen distinctly enlarged. No abnormal physical signs in heart or lungs.

Next day, at Dr. Sinclair's visit at noon, she was insensible, and had been having convulsions since 6 A.M. The pupils were dilated and sluggish, the pulse was 120 and bounding, and the temperature 102°. The tongue was protruded, and bore marks of biting by the teeth. She was then ordered to have half a drachm of hydrate of chloral by enema, which was to be repeated in two hours if necessary, and, if still unable to swallow in the afternoon, she was to be fed by pancreatised enemata. At ten minutes past 3 P.M. she died.

Necropsy.—On opening the dura mater, a thin layer of yellow lymph was found to be uniformly distributed all over the pia mater. No evidence of extension from the middle ear or from any part of the temporal bones. The spinal canal was opened, and lymph, continuous with that on the brain, was found all down the cord, most markedly about the middle of the dorsal vertebræ. The cranial and vertebral bones were healthy. The lungs were congested. Abdomen: Intestines congested and moderately full of semi-fluid fæces. Careful examination showed no lesions of Peyer's patches. The spleen was enlarged and pulpy.

Remarks by Dr. SINCLAIR.—There can, I think, be no doubt that this case was an example of the more severe type of cerebro-spinal meningitis. The initial and subsequent symptoms were sudden and overwhelming; the patient was evidently beyond hope when she was admitted on the third day; and the post-mortem examination showed that both the cerebral and spinal meninges had been acutely inflamed. And there can be as little doubt that the case was isolated and unassociated with any epidemic outbreak, because there had been no similar case in the neighbourhood for a long time before, and I have not been able to find any trace of a similar case up till now (Jan. 27th, 1887). No traumatic cause could be ascertained after a very careful and exhaustive inquiry. The clinical history is singularly complete except in the one respect of the absence of the eruption, which is so often associated with this interesting and fatal malady. Isolated as it is, I think it worthy of being placed on record, as a contribution to our knowledge of a very rare disease.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

"Induration" of Hunterian Chancres in the Female.—Actinomycosis Hominis.

AN ordinary meeting of this Society took place on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Mr. W. E. CANT contributed a paper on some Clinical Observations on "Induration" in the Primary Lesion of Syphilis in Women. (Communicated by Mr. Holmes.) The following results were founded on about 3900 cases examined in the Royal Albert Hospital, Devonport, during a period of six and a half years. In contradistinction to the generally accepted fact that in men induration is as a rule well marked, it is so in women far less generally. The induration, which is described as being circumscribed, limited to the base of the sore, and clearly marked off from the surrounding tissue in men, in women is, about as often as not, diffused a considerable distance into the tissues around, often very widely, not sharply defined from the surrounding tissues, nor circumscribed in the base of the sore itself. The most typical form of primary sore with its induration, resembling a disc of cartilage set in surrounding soft structures, described as being frequent in men, is seldom met with in women. Every variety as to the degree of development of the induration is met with in women; but there is a large proportion in which it is very slight (about one-third). In some of these slight cases it is impossible to affirm that there is any thickening at all present, and there is a small number in which none exists throughout the whole course of the sore. Induration is present in the early stage of the sore only in a small proportion of cases. The time of its occurrence in the course of the sore varies greatly; it may occur at almost any period of its course. It becomes most marked and developed towards the middle and latter part in many cases. Tables of cases of primary sores, grouped according to their clinical character, and showing "when first apparent," "characters at earliest period," &c., and also of five cases of infecting primary sore in which there was no induration, were appended to the paper. — Dr. C. R. DRYSDALE said the subject of induration at the commencement of syphilis had at times become much confused. He had gathered much the same impression as Mr. Cant, in his observations made at a small lock hospital. The initial chancre might be but little indurated in women. The tissues in the female genital organs were rather different from those of the male, and this condition probably influenced the occurrence of induration. In a hard chancre of the lip in a woman the induration might be quite "wooden." A large number of cases in the male might exhibit but slight induration. In his own experience, of 241 cases four-fifths occurred on the labia majora and minora. The initial hard sore might occur on the os uteri. He had not seen one on the vagina.—Mr. HARRISON CRIPPS hardly agreed with Mr. Cant that the locality made no difference in the occurrence of induration. He thought position was everything. On the lip induration could easily develop. In chancre on the finger there might be absence of induration, even from beginning to end. Hunterian sores on the face and fingers indeed were generally free from induration. —Mr. T. HOLMES said the paper differed from most records of observations in being a record simply of facts. No mere opinion was expressed in the paper. Works of syphilographers gave a record of general impressions, not of actual facts of which notes were made at the time. He believed that the situations of the sores were given in the tables appended to the paper. The conclusions of the author were in accord with his own experience. He considered it a matter of regret that the Contagious Diseases Act had been repealed.—Mr. R. W. PARKER asked, if induration was not the test of a chancre, what was the test? What is the characteristic feature of a chancre? How much of the features was due to mere irritation, and how much to the action of the true syphilitic virus?—Dr. C. R. DRYSDALE said that it was not to be supposed that absence of induration meant identity of the Hunterian sore with a soft one.—Mr. CANT, in reply, said the situations of the sores were given in the paper; two occurred on the os uteri, and one on the vaginal wall. Some of the sores on the buttock were indurated—this in opposition to Mr. Cripps. Induration was the best character of a syphilitic chancre when present. His paper did not, however, deal with the characters of syphilitic sores.

Dr. R. G. HEBB contributed a case of Actinomycosis Hominis. (Communicated by Dr. Sturges.) A boy, aged eleven, was admitted into the Westminster Hospital on March 18th, 1886. He had suffered for a month previously from pains in the limbs, diarrhœa, vomiting, and "feverishness." On admission the most prominent symptoms were those of lung consolidation and pleural effusion, for which he was tapped twice. Soon afterwards pyæmic symptoms developed, and the patient died on June 2nd. The post-mortem examination disclosed abscesses of the brain and meningitis, pneumonia, excavation of the lungs, and suppurative pleuritis. A large vegetation was found on the wall of the right auricle of the heart, and in the liver an abscess and many areas of caseation. On microscopical examination of the liver, there were found numerous pigmented cells, many of which formed the centre for the departure of radiating filaments. The conjunction of these two factors gave rise to the appearance of a definite organism, for which the name of actinomycoces was adopted. In the brain and lungs collections of cocci only were found.—Dr. STURGES testified that Dr. Hebb had taken an immense deal of pains about the pathological preparations. The paper read by Dr. John Harley tried to show that the morbid appearances were due to tubercle, but he could not agree with this view. The boy came in with pneumonia, and developed hectic fever and an empyema. Three things were clear: first the pneumonia, then the wasting fever, and there were also signs in the liver, which was explored two or three times with the aspirator. There were now at least three cases of this disease starting in the lung. The clinical aspect was alike in the three cases—Israel's, Markham Skeritt's, and the present one; and a diagnosis ought to be possible from the clinical characters. The present case was shorter and acuter than the other two; the duration was two or three months. The onset was gradual, the symptoms being those of diarrhœa and loss of appetite preceding the signs of pneumonia.—Dr. T. D. ACLAND said the disease was not

Digitized by Google

nearly so rare as Dr. Sturges thought it to be. He had seen no less than four cases himself. The disease was very common in cattle, and thirty cases of disease of the lung in human beings had been reported in Europe. In Dr. Hebb's specimen the organism did not seem to be the central point of the morbid process. It seemed as though the organisms were lying in holes bounded by fibrous tissue. He had cut sections of Dr. Hebb's specimen without being able to find any organism. Whether the disease was caused by the organism he could not say. Naked-eye appearances were not sufficient to diagnose the disease if it were called actinomycosis.—Dr. HEBB said a similar case was reported by Vacchetta in the *Veterinary Journal* of Milan for 1882; it occurred in a dog, and was thought to be a sarcoma of the lower jaw. He thought that Dr. Acland supposed that the sections were only three in number on which the diagnosis had been made.

MEDICAL SOCIETY OF LONDON.

Partial Enterocele.—Parotitis after Abdominal Operation.—Rupture of Aneurysm into Pericardium.

AN ordinary meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Mr. EDMUND OWEN read a paper on Littre's hernia, which appears in full on page 311.—Mr. BRUDENELL CARTER said the French were not alone in varying the spelling of their proper names. He objected to the use of proper names to designate diseases—a method serving to confuse students.—Dr. C. J. HARE said the nomenclature of disease as issued by the College of Physicians went far in the direction of not using proper names for designating diseases, but no doubt would go further if representation were made on the matter to the Registrar.—Mr. F. TREVES referred to the diagnosis, which was not perfectly clear from the symptoms. The extreme rarity of hernial diverticula on the left side of the body was against the diagnosis. The influence of the ice-bag in producing the abscess was of interest. He believed that the prolonged use of the ice-bag might cause abscess and gangrene. As to Littre's hernia this much might be said, that it was doubtful whether Littre had ever seen a case of partial enterocele. Richter's hernia was the best name to designate the hernia by, since he was the first actually to describe it.—Mr. STEPHEN PAGET referred to a case of incarcerated hernia in a lady which was treated with an ice-bag and followed by an abscess.—Mr. WALTER PYE considered that the phrase "lateral enterocele" was barren of meaning.—Mr. DAVIES-COLLEY asked what evidence there was that this was not an ordinary femoral hernia injured by Gimbernat's ligament; the abscess had slowly come to the surface through the crural canal.—Mr. J. H. MORGAN inquired whether there was any indication of the portion of the bowel that had been the seat of strangulation.—Mr. J. BLACK suggested that iced applications in peritonitis might increase the shock.—Mr. E. OWEN, in reply, maintained that it was a partial, not complete, obstruction of the bowel. The ileum on the side away from the mesentery was the part of the bowel affected.

Mr. S. PAGET read a paper on 101 cases of Parotitis after Injury or Disease of the Abdomen or Pelvis. He referred to Graves' 30th Clinical Lecture, on the Connexion between Diseases of Different Organs. He also referred to the fact that abscess of the kidneys and of the muscular substance of the heart is much more common in pyæmia after acute necrosis than in pyæmia after amputation. In 18 cases of pyæmia after acute necrosis, 10 had abscess of the heart, and 11 had abscess or infarction of the kidney. But in 140 cases of pyæmia after amputation, only 1 had abscess of the heart, and not one had abscess of the kidney. Another morbid sequence of a similar kind is shown in the fact that abscess of the liver or of the spleen is much more common in pyæmia after injury involving the medulla of bone, than in pyæmia after injury involving only the soft parts. In 67 cases of pyæmia after injury involving only the soft parts, 4 had abscess of the liver, and 3 had abscess of the spleen. But in 217 cases of pyæmia after injury involving the medulla of bone, 56 had abscess of the liver, and 28 had abscess of the spleen. These morbid sequences are of very great interest, as revealing relations between remote organs which are never shown in health. Physiology knows of no connexion between the periosteum, the heart, and the kidneys; or between the medulla of bone, the spleen, and the liver. Another morbid sequence is parotitis after injury or disease of the abdomen or pelvis. Out of 101 cases, 10 followed injury or disease of the urinary tract; 18 followed injury or disease of the alimentary canal; 23 followed injury or disease of the abdominal wall, subperitoneal or pelvic cellular tissue, or peritoneum; and 50 followed injury or disease or temporary derangement of the generative organs. Under "temporary derangement" Mr. Paget included such causes as slight injuries, menstruation, &c. Parotitis, after injury of the *extremities*, is always part and parcel of a true general pyæmia, with other secondary inflammations elsewhere. But this parotitis after abdominal or pelvic lesions was, in 93 cases out of 101, an isolated event, unaccompanied by any other inflammation like itself. In only 15 of the 101 recorded cases was there distinct mention of "septic symptoms," "septicæmia," or "pyæmia." Of the 101 cases, 37 died. But of these 37, 3 were over eighty, 3 had cancer, 2 had perforation, 2 had strangulated hernia; others had acute peritonitis, severe injuries, septicæmia, or pyæmia. Thus the danger is not in the parotitis itself, but in the primary lesion which causes it. This form of parotitis has no period of incubation; it has been observed on the first day after the primary lesion, and on the nineteenth, and on the intermediate days also; to say nothing of a case where it came on the morning of the day fixed for operation. It seems to come later when it is due to delivery or abortion than when it is due to operations on the generative organs. The onset of this form of parotitis is rarely attended by much disturbance of the general condition of the patient. Rigors are mentioned only in 4 cases; delirium or puerperal mania in 6 cases. In the great majority of cases there is only slight rise of temperature, no rigors, no high fever. Such cases have been well described by Dr. Macdonald of Edinburgh, Dr. Goodell of Philadelphia, and many others. As regards the termination of this parotitis, by resolution or by suppuration, there are only 78 cases which give information on this point. Of these, 45 went on to suppuration and 24 died; whereas of the 33 that were resolved without suppuration only 1 died, and she died of cancer a month after colotomy. Death in the fatal cases was due not to the suppuration of the parotid but to old age, cancer, perforation of the bowel, &c., or to septicæmia or pyæmia. They did not die because the parotitis went on to suppuration, but it went on to suppuration because they were going to die. Mr. Paget suggested that this suppuration of the parotid in cases of pyæmia might be allied to those cases of pyæmia after compound fracture where suppuration occurs round simple fractures inflicted at the same time as the compound fracture, and to the experiments of Chauveau, Loeffler, and others, who produced simple fractures in animals, then injected septic fluids into their veins, and thus produced suppuration round the simple fractures. Mr. Paget spoke of the surgical features in some cases of this form of parotitis, and of the treatment by belladonna and by incision, according to the old rule, "Parotitides omnes ante maturitatem aperiendæ." He had lately, by the kindness of Mr. Knowsley Thornton, made a post-mortem in the case of a woman who died ten days after the removal of a very large sarcoma from the mesentery. Swelling of the left parotid gland set in three days before death. The operation had been one of great severity, and she never thoroughly rallied from it. Necropsy (seven hours after death): No rigidity of limbs or of neck; jaws tightly clenched, and could not be opened. Abdomen flat and collapsed; operation wound healed. Firm non-fluctuating swelling of left parotid. Pus wells freely into the mouth, when pressure is made over the gland. The mucous membrane of the mouth is soft, clean, and wholly free from sordes or ulceration. The mouth of the duct is just marked by one or two tiny points of hæmorrhage under the mucous membrane. A bristle passes freely up the duct. The skin and loose cellular tissue over the parotid and in the anterior triangle of the neck are œdematous and full of serum; the lymphatic glands at the angle of the jaw and in the neck are much enlarged and soft. On section, the parotid is found everywhere evenly infiltrated, not with pus, but with reddish, slightly turbid serous fluid, looking like the cut surface of a spleen. There is no pus in the gland itself, but just at the proximal end of the duct, where it leaves the gland, are two or three drops of healthy pus and a minute calculus no bigger than a millet-seed. There is no general peritonitis, but a small circumscribed abscess at the seat of the operation. Spleen large and diffluent. No marked lesions elsewhere. The

Digitized by Google

microscope showed the acini and lymph spaces of the gland invaded by masses of small round cells (lymph cells), which here and there could be seen inside the acini and ducts. The gland tissue was broken up and confused by these masses of cells; but the interlobular septa of fibrous tissue were for the most part hardly changed at all. It was a true inflammation of the gland tissue itself. As to any micro-organism, Rosenbach has grown colonies of staphylococcus pyogenes aureus from the purulent infiltration of the parotid, in a man who died with "acute septic peritonitis," after operation for strangulated hernia. But this micro-organism has no specific value. In conclusion, Mr. Paget observed that this form of parotitis, which follows abdominal or pelvic injury or disease, is, in many ways, of great interest. In 93 cases out of 101 it was an isolated event. It has no period of incubation, and no regular course. It may subside and recur and subside again, or may attend each pregnancy or each menstruation. It is rarely marked by much fever or disturbance of the system; indeed, in many cases it is "critical" rather than "symptomatic"; and out of 33 cases where it was resolved without suppuration, only 1 died, and she died of cancer. In only 15 cases is mention made of "septicæmia" or "pyæmia." Neither is it due to the spreading of inflammation from a parched and sordid mouth up the duct into the gland. In only one or two cases was the socia parotidis involved at all; nor are the mouths of patients with abdominal or pelvic lesions more parched than those of other patients. It is a pure theory, not supported by any evidence. Nor is it due to inflammation of the lymphatic tissue in the substance of the parotid. The characters and histories of the case render such a view impossible. Even although some of the cases are best explained in one or other of these ways, there are others which cannot thus be explained. But there are many reasons for believing that the reflex nervous system may, at least in part, be a cause of this parotitis. The influence of the nervous system on the salivary glands, both reflex and direct, is familiar to all. Experimentally, Paulow has found that if a loop of intestine be kept drawn out from the abdomen of a dog, the action of the gustatory nerve is inhibited, and the secretion of saliva is checked or arrested, until the loop of intestine is put back. The observations of Pasternatski on the changes of the pupils during various diseases are also of interest in this connexion. Now, if the same lesion produces salivation in one patient, arrest of salivary secretion in another, and swelling of the salivary glands in a third, must we not conclude that all three are different workings of the same agent? Thus, gastritis may cause salivation, or arrest of saliva, or parotitis. So, too, parotitis may follow gastric ulcer, gastrostomy (2 cases), duodenal ulcer, enterostomy (2 cases), herniotomy (5 cases), hepatic abscess, abdominal cancer (2 cases), typhlitis, colotomy, the removal of abdominal or umbilical tumours (3 cases), penetrating wound of the abdominal wall, and peritonitis (8 cases). It has also followed division of stricture of rectum, and operation for hæmorrhoids; and with these last two cases may be compared the fact that salivation has been observed as an early symptom of cancer of the rectum. Again, derangement of the generative organs, like derangement of the alimentary canal, may be followed either by salivation, or by arrest of saliva, or by swelling of the salivary glands. The salivation of pregnant women, and their longings for sapid food, are well known; and the same thing may occur during menstruation. Dr. Goodell gives two cases: one, of excessive salivation just before and during menstruation; the other, of a lady with a congested and tender left ovary, in whom the left parotid gland did not secrete during menstruation, so that the mouth and fauces on that side remained dry and painful. So, too, parotitis has been known to accompany each pregnancy, and to accompany or replace the menstrual flows (two cases). It has followed various trivial derangements of the generative organs (4 cases), pelvic abscess or hæmatocele (4 cases), operation for lacerated cervix (4 cases), other operations on vagina or uterus (4 cases), delivery or abortion (8 cases), the menopause (2 cases), and ovariotomy or oöphorectomy (27 cases). So, too, after lesions of the urinary passages, parotitis has followed the use of the catheter (3 cases), the use of the sound, renal abscess, and cystitis (5 cases). It is certain that, though some of these cases were due to septicæmia or pyæmia, others were not. Surely they are analogous to the retention or suppression of urine which so often follows abdominal and pelvic lesions. They are not due to a mere reflex spasm of the mouth of the duct, such as Verneuil describes; for this, as shown by many cases collected by M. Terrier, causes a mere passive dilatation of the gland, which alters with every meal, never disturbs the general health, never suppurates, and disappears when a probe or catheter is passed up the duct. Rather, while admitting the influence of the constitutional condition of the patient, we must believe that in many of these cases of parotitis there is a reflex vaso-motor constriction of the arteries of the gland itself, which, as Mr. Knaggs of Huddersfield has suggested, may be followed by a reaction going on to parotitis.—Mr. ALBAN DORAN discussed the question of the mode of origin of the parotitis. It could not be said that it was always a question of some connexion between the generative organs and the parotid gland, because injury of other parts of the abdomen was followed by parotitis. He examined the theories of simple reflex action, local septic infection, and mere constitutional debility, with attendant local conditions about the opening of the duct of the parotid into the mouth.—Mr. W. A. MEREDITH raised the question whether in parotitis after ovariotomy the parotitis occurred on the same side of the body as that whence the ovarian tumour was removed. In one case of his own the relationship was crossed—the right ovary and the left parotid.

Mr. HUGH SMITH read a case of Rupture of Aortic Aneurysm into the Pericardium. It occurred in a washerwoman aged forty-two, who died whilst working at the washtub. The specimen was exhibited, and showed dilatation of the first two parts of the aortic arch; the third part of the arch showed a saccular aneurysm, which opened into the pericardium by a rent three-quarters of an inch in length; as much as fifteen ounces of fluid and clotted blood were found in the pericardium. There was collapse of the left lung. During life signs of consolidation were noted at the apex of the left lung, but there were no laryngeal or pupillary signs.—Mr. MARMADUKE SHIELD related cases of aneurysm of the aorta in which the patients continued to go about doing their work till death occurred.—Mr. J. BLACK considered it of interest that the aneurysm should have originated in the third part of the aorta and yet have burst into the pericardium.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

AT a meeting held on January 21st, Dr. Septimus Gibbon in the chair,

Dr. C. E. SAUNDERS read a paper on "Legislation for the Purification of Rivers, and its failure." Dr. Saunders traced the abortive attempts at legislation up to the time of the passing of the Rivers Pollution Prevention Act of 1876. He showed that this Act had been scarcely better than a dead letter; that in eight years legal action to enforce its provisions had been taken only in fifty-six cases; in these, twenty-six orders had been made to restrain pollution, but a great number of such orders had never been actively enforced. Of the twenty-six orders, twelve had been obtained at the instance of two authorities. Out of the fifty-nine County Court circuits in England and Wales, in only twenty-seven had proceedings been taken; in fourteen of them there had only been one case each. No less than nineteen out of the fifty-six cases were prosecutions against the sanitary authority, the very persons to whom the exclusive carrying out of the Act is entrusted. As to any spontaneous action to prevent pollution, the rivers bear testimony of failure in that direction. Dr. Saunders considered that trade interests militated against any effective legislation, and deprecated making manufacturing pollutions the chief object of prevention, these being, in his opinion, of far less consequence from a health point of view than sewage pollutions. He, however, quoted the opinions of the Rivers Pollution Commissioners, which show that "there is not one trade pollution which cannot be kept out of the streams altogether, or so purified before admission as to deprive it of its noxious character, and this without unduly interfering with manufacturing operations, but even in some instances with a distinct profit to the manufacturers." Some streams are so filthy that they are even unfit for manufacturing purposes, and the value of clean river water in such cases is estimated by manufacturers at from £50 to £1000 a year. The author urged the importance of attacking the very filth-beginnings of rivers—sewage ditches; and pointed out the good effects

Digitized by Google

this would have on general sanitation, as well as on river purity, especially adhering to the old view, that diphtheria is largely, if not entirely, a filth disease. He next gave the heads of a Bill which had been drafted by Mr. Willis Bund, which it was intended to introduce into Parliament at the earliest opportunity. This Bill makes it obligatory, instead of permissive, on the sanitary authority to prosecute offenders against its provisions, and if they (the sanitary authority) fail to institute, or, having instituted, fail to prosecute with due diligence, then any person having a legal right to make complaint may apply to the judge of the County Court for leave to prosecute in the name and at the cost of the sanitary authority. Dr. Saunders then sketched the machinery by which any future Act should be carried out, and advocated the establishment of a central authority, having no other function whatever than that of attending to river purification, looking to the medical officers of health of the various districts for detailed and periodical information. Dr. Saunders concluded his paper with the following remarks: "The policy of 'pass-it-on' is too great a temptation to put in the way of local sanitary authorities, for although they suffer in their turn, still it is convenient to get rid of their sewage, and the river is a costless and convenient vehicle. If I might venture to paraphrase a verse of Horace I should say—

'Sanitas exspectat dum amnis defæcat .....'

And unless more effective legislation is provided in the future than there has been in the past, one may find an application to the completion of the line and couplet—

..... 'at ille
Labitur et labetur, in omne volubilis ævum.'"

In the discussion which followed, Drs. Gibbon, Swete, and Woodford took part.

MIDLAND MEDICAL SOCIETY.

A MEETING of the Society was held on Jan. 19th, Mr LLOYD OWEN, F.R.C.S.I., President, in the chair.

Fracture of Spine.—Dr. SUCKLING showed a youth, aged eighteen, who at the end of last September had fallen twice upon his back. When seen four days after the second fall he was unable to stand, but could move his legs when in the recumbent position; he was unable to turn over in bed; had girdle pains in the upper lumbar region and shooting pains over the iliac bones. There was no anæsthesia, no actual paralysis, no bladder trouble; but the first and second lumbar spines were prominent, and great pain was elicited on light percussion over them. The right cremasteric reflex was lost, and the temperature varied from 99° to 102° for a week after admission. Under treatment by a plaster jacket these symptoms have now almost entirely disappeared. Dr. Suckling considered that there had been a fracture through the arches of one or more of the lumbar vertebræ with irritation of the last dorsal and first lumbar nerves.

Meckel's Diverticulum.—Mr. A. F. CLAY showed a specimen of Meckel's diverticulum from a girl aged thirteen. She had swallowed a number of plum-stones, and for the removal of these had taken strong purgatives. When first seen by Mr. Clay, ten days after swallowing the stones, she was suffering from peritonitis and obstruction. He opened the abdomen in the middle line and found a quantity of purulent fluid in the peritoneum, the intestines being matted together. The peritoneum was washed out, and a distended piece of intestine opened and stitched to the wound. The patient died from exhaustion thirty-six hours after the operation. At the post-mortem examination a Meckel's diverticulum was found with its ligament attached to the mesentery; a piece of the ileum below this had got under the loop, and was firmly strangulated, ulceration and perforation having taken place.

Dermoid Cyst of Ovary.—Dr. MALINS showed an ovarian cyst containing a quantity of oily material that solidified on its removal from the body, and a mass of hair.

Enlarged Ovary.—Dr. MALINS also showed an enlarged and cystic ovary from a patient aged twenty-five. Both these cases had been subjected to operation, and both had recovered without a bad symptom.

Vesical Calculi.—Mr. HASLAM showed twelve uric acid calculi, weighing altogether one ounce and three-quarters, that had been removed from the bladder of a female subject in the Queen's College dissecting-room. The bladder was much hypertrophied, but nothing was known of the previous history of the case.

Dr. FOXWELL read a paper on Acute Peritonitis in its Medical Aspect.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE fourth meeting of the session was held in the Faculty Hall on Jan. 26th, Dr. Samuel Sloan, President, in the chair.

The PRESIDENT exhibited a model of the Incubator in use at the Maternity, and made some remarks upon the current experiment with Triplets.

Dr. MURDOCH CAMERON showed a Fœtus at the sixth week with Membranes, &c.; and also a Fœtus at the fourth week, with Amnion, Chorion, and remains of Umbilical Vesicle.

A Review of Thirteen Years' Private (Obstetric) Practice.—The adjourned discussion of Dr. J. K. Kelly's paper was then taken up by Mr. J. S. NAIRNE, who said Dr. Kelly was fortunate in having had no cases wherein delivery had not been possible by means of forceps. He could not imagine such an amount of distensibility as that contended for compatible with a healthy pelvis. He had never observed any "erection of the hip" during labour. Nevertheless, the pelvis was normally capable of a slight amount of distensibility; but he thought the joint most capable of it was the lumbo-sacral, which allowed, certainly not a *dilatation*, but an adjustment of fœtus to the pelvis. He objected to, and repelled, Dr. Kelly's views as to the occurrence of ruptured perineum to such an extent as to require perineorrhaphy.—Dr. PARK objected to "bad nursing" being accepted as an efficient cause of death post partum, and to Dr. Kelly's wholesale condemnation of ergot, especially for hemorrhage, and thought he had been extremely lucky in never having had either a case requiring craniotomy or a case of death from post-partum hemorrhage.—Dr. W. L. REID thought Dr. Kelly's practice wrong in respect of rupture of the perineum, and that it was dangerous practice to apply the straight forceps at the pelvic brim. He also believed first labours to be more dangerous than subsequent ones.—Dr. ABRAHAM WALLACE said that the luxation of the lumbo-sacral articulation during labour had been drawn attention to before. He thought such an amount of general pelvic distensibility as Dr. Kelly contended for was not according to fact.—Dr. OLIPHANT thought moderate ruptures healed very well without stitching.—Dr. SLOAN thought straight forceps inadequate for use at the pelvic brim, and that a double-curved instrument should always be used. He places his pad somewhat higher than "over" the uterus, and administers ergot as a routine, as it kept the uterus retracted. He had observed distensibility of a marked kind only in one case, and in it a firm binder had to be adjusted post partum, in order to enable the patient to walk comfortably. He did not reck on rupture of the fourchette as rupture of the perineum, as that occurred in almost every case. He considered there were three degrees of perineal rupture—viz, 1. Where a few fibres only were torn. 2. Where it went within a quarter to half an inch of the anus; this should be stitched *at once* thoroughly. 3. Where it passes through the anus, when, as a matter of course, stitching is necessary.—Dr. KELLY, in reply, adhered generally to the positions contended for in his paper.

Dr. GEO. HALKET then read a paper on the Obstetrical and Gynæcological Cliniques of Berlin and Vienna, which was listened to with great attention, and frequently elicited the applause of the Fellows. He also exhibited the obstetrical and gynæcological instruments in common use at Vienna.

ROTHERHAM HOSPITAL.—The annual general meeting of the subscribers to this institution was held on the 27th ult., when the committee reported that the total number of patients during 1886 was 4092, of whom 189 were in-patients and 3903 out-patients. The receipts amounted to £1571, and the expenditure to 1493. The new ward now in course of erection is almost completed, and as when it is occupied a larger income will be necessary, the committee appeal for increased support.

AT the annual meeting of the subscribers to the Tavistock Dispensary on the 25th ult., it was resolved to erect a cottage hospital in connexion with the institution.

Reviews and Notices of Books.

The Surgeon's Pocket-book. An Essay on the best Treatment of Wounded in War. Especially adapted for the Public Medical Services. By Surgeon-Major J. H. PORTER, late Assistant Professor of Military Surgery, Army Medical School, Netley. Third Edition. Revised and edited by Brigade Surgeon C. H. Y. GODWIN, Medical Staff, Assistant Professor of Military Surgery, Army Medical School, Netley, late Medical Officer of the Royal Arsenal, Woolwich. London: Griffin and Co. 1887.

THE basis of this work was originally an essay selected for the prize offered by Her Majesty the Queen of Prussia and Empress of Germany on the "Practical Treatment of the Wounded in War." The adjudicators were Professors Billroth of Vienna, Baron von Langenbeck of Berlin, and Socin of Basle. The first edition was published in 1875, the second in 1879, with a preface by its author dated Cabul, in September of that year, where, to the great loss and grief of the army in Afghanistan, Surgeon-Major Porter soon afterwards perished of pneumonia. The present, or third edition, is in many respects another book altogether. It possesses some historical sort of interest in this respect, that it enables one to trace the progress and changes that military surgery has undergone in the interval. The first edition received the stamp of official recognition in the "Précis of Medical Arrangements," published for the guidance of medical officers in the Afghan campaign. The present editor—Brigade Surgeon Godwin—has introduced so much that is new, practical, and in our opinion sound, that we can without affectation recommend this "Surgeon's Pocket-book" as an invaluable guide to all engaged, or likely to be engaged, in field medical service; in fact, we do not know of any other book of the kind that contains the same amount of pertinent information in the same compass. The key to the changes he has effected is to be found in the substitution of antiseptic for "antiphlogistic" in the treatment of wounds and injuries. The amount of revision that the book has undergone and the new matter that has been added will be more easily appreciated by examining these a little in detail. The following may be taken as samples At page 2 a stretcher section is described. At page 17, *et seq.*, a clear and correct précis is given of the present arrangements in the army for service in the field (illustrated by the frontispiece), which is likely to prove really useful. At page 22 there are a few new remarks on "shock." At page 41 there is a short paragraph on "fat-embolism." Then follows a brief account of the theory of Listerism, with details for wound treatment in general and remarks on the chief antiseptics. At page 49 the treatment of special wounds, or those which have already taken on unhealthy action, is given, followed by Reyher's experiences and rules for treatment of gunshot injuries. At page 57 Surgeon-General Cammerer's experience in Roumania during the last Russo-Turkish war is given. The lesson to be learnt from that experience is that his success should impress the importance of surgeons at different hospitals on a long line of communications not losing heart because wounds come to them septic from exposure and inattention. There is some new matter under the head of wounds of the abdomen: for instance, at page 102, in the way of suggestion of free incision in diffuse peritonitis; and at page 103, regarding the question of laparotomy in injuries of the abdomen where viscera are injured, and where foreign bodies have penetrated and have to be removed. At page 120 some rules are offered for guidance respecting gunshot fractures of the femur, where the situation, and especially the factor of rest afterwards greatly influence the treatment. It is pointed out how nearly hopeless it is to try to save the limb if the patient has to be carried day after day, &c. At page 232 there is a useful table of water rations required for man and animals; and a typical war ration as a guide for medical officers, followed by excellent and precise information regarding air-space and ventilation. Considerations of space compel us to omit by far the larger number of revisions of and additions to the text. The four appendices are new, and contain some excellent formulæ and useful information. The third contains a translation of the orders recently issued to the Medical Department of the German Army, which is calculated to afford medical officers—serving in India for instance—useful hints of what to do when suddenly ordered to prepare for a flying column, and so forth.

Sanitary Examinations of Water, Air, and Food. A Vademecum for the Medical Officer of Health. With 110 illustrations. By CORNELIUS B. FOX, M.D., F.R.C.P. Lond., formerly Medical Officer of Health of East, Central, and South Essex. Second Edition. London: J. and A. Churchill. 1886.

DURING the eight years that have passed since the publication of the first edition of Dr. Cornelius Fox's book much valuable labour has been devoted to sanitary science and many new methods have been described. Dr. Fox has industriously studied these modern methods, and in the present edition gives us the benefit of his work. A considerable portion of this book is new, and all the leading authorities have evidently been consulted. In the section devoted to water, the most important addition is a clear and well-illustrated description of the biological methods, chiefly founded on the researches of Koch, which have attracted so much attention of late years. The field is promising, and already a crop of useful results has been gathered by Dr. Percy Frankland, Dr. Tidy, and others; but as yet no certain inferences can be founded upon the experiments, for bacteriology is still in its infancy. The influence of bacteria in nitrification and denitrification might with advantage have received more notice. To the latter process, a very important factor in the destruction of sewage matters in river water, Dr. Fox hardly alludes, and we gather from some words on page 100 that he has not read or has misunderstood the interesting results arrived at by Dr. Angus Smith in one of the latest, if not the latest, researches of his useful life. In the presence of excess of sewage, nitrates are rapidly reduced, the nitrogen escaping as gas. As in so many other cases in chemistry, oxidation and reduction seem to go on simultaneously. A section is given to the very important question of dissolved oxygen, about which, as yet, we have by no means heard the last word. Schützenbergen's process, based on the use of sodium hyposulphite (the true hyposulphite $Na\,SO_2$, and not the thiosulphate $Na_2S_2O_3$ commonly known by the name), is described with sufficient clearness. In skilful hands it is simple and satisfactory, but Dr. Fox does not sufficiently insist on the absolute necessity of working quickly and excluding even momentary exposure of the sample to the air. The velocity with which water takes oxygen from the air is marvellous, and the neglect of proper precautions for the exclusion of air has rendered mere determinations of dissolved oxygen worthless. With regard to the determination of organic carbon and nitrogen, we are inclined to think that Dr. Fox underrates the importance and overrates the difficulty of the method of Frankland and Armstrong. It is, with certain well-known restrictions, accurate as well as valuable when properly carried out. It was, however, wiser to exclude it from a manual intended for medical officers of health, who have seldom had the training of professional chemists.

The section dealing with air is about equal in length to that devoted to water. There is a great deal of valuable matter in it, particularly in regard to microscopic examination, which is constantly becoming more efficient, and therefore more important. There are some useful directions in regard to meteorology, and a chapter on ozone, in which, however, we find some serious defects. The simultaneous formation of ozone and peroxide of hydrogen is now well

Digitized by Google

known, and should have been noticed, and to say that "peroxide of hydrogen is produced by a combination of the oxygen of the air with water" is a very loose way of stating the facts.

In the last section, which treats of the sanitary examination of food, the best chapters are those which describe the inspection of meat, poultry, and fish. In this and in the simpler methods for food analyses, the author is at home; but he would have been wise, considering his limits of space, to have omitted the complete quantitative analysis of food, for which his directions are entirely insufficient, and in some cases misleading. On the whole, however, in spite of some defects, Dr. Fox's manual is a good sound piece of work, and will be of great value, not only to medical officers of health, but to all who are interested in sanitation—that is, to the whole medical profession.

Outlines of Quantitative Analysis. By A. HUMBOLT SEXTON, Professor of Chemistry in the College of Science and Arts, Glasgow. London: C. Griffin and Co. 1887.

THE writer of an elementary text-book is nearly sure to say in his preface that he thinks his work will supply a want. Too often he is alone in his belief; and we have of late years been flooded with such books or booklets, many of them absolutely unnecessary, and many worse than useless. Professor Sexton tells us the usual story, but in his case we are bound to admit that the story is perfectly true. A compact laboratory guide for beginners in quantitative chemical analysis was wanted, and the want has on the whole been well supplied. Even among students who do not intend to make chemistry a profession there are many who can afford the time and would gladly devote the labour necessary for the study of elementary quantitative analysis. Apart from its practical utility, the mental and mechanical training gained in exact scientific work is of infinitely higher value than the careless and slovenly test-tube messing which is so often mistaken for practical science. At some few schools, notably at Epsom College, elementary quantitative analysis has been introduced among the more advanced students with signal success. To those teachers and students who are willing to devote the time necessary for real scientific work in chemistry Professor Sexton's little book will be useful. It is not quite free from faults, but as far as we have seen it is accurate; the descriptions are clear and sufficiently full, and the examples chosen are for the most part well selected. The few faults which we have to find are of a secondary character. Now and then we regret the absence of some well-known simple and useful method—such, for example, as the estimation of copper by electrolytic deposition on platinum; but more frequently we are inclined to complain of the somewhat too wide scope which the author has permitted himself. Ultimate organic analysis, for example, including combustion in oxygen and Dumas' process for the estimation of nitrogen, cannot be sufficiently explained in so short a space, and no student would attempt it without fuller directions. Then the apparatus described is often more elaborate than is really necessary; and altogether the book, good and useful as it is, will be apt to frighten students who have neither much money nor much time at their disposal.

New Inventions.

POCKET SURGICAL INSTRUMENT CASE.

MESSRS. ARNOLD AND SONS, of West Smithfield, have made us a small pocket surgical instrument case, which will, I think, be found a boon to general practitioners. The average surgical dressing case is far too large and cumbersome to be habitually carried about in the pocket, consequently it frequently happens that it is not at hand when most wanted. A case is required containing a few of the necessary emergency instruments, yet so small that it may *habitually* be carried about without causing inconvenience by its bulk. The annexed woodcut depicts such a case, containing scissors, dressing forceps, artery forceps, probe and director, abscess knife, and gum lancet, with pockets for sutures and needles. The dimensions are as follows: length, 3 in., width, 2 in., thickness, ¾ in. Pocket cases intended to answer this

purpose are sold by several makers, but the instruments being placed *in two rows* the case is rendered so thick as to entirely defeat the object for which it is made. In the above cases the few absolutely necessary instruments are laid as flat as possible *in one row*, and thus the outside thickness of ¾ in. is obtained. The case fits easily into the watch or waistcoat pocket. WILLIAM D. STEEL, M.D.

BASDON'S CHLORIDE OF AMMONIUM INHALER.

THE catarrh-producing winter through which we are passing has given unusual interest to all devices for removing aural catarrh, of which the various inhalers for the use of chloride of ammonium are amongst the most valuable. We have tried the above inhaler, and can express our approval of it. It is well made and easily used. The materials of it are good; the cork of the bottle as well as the tubes and the stopper of the sponge tube are made of fine indiarubber. It has the great advantage of cheapness, is simple in construction, and works well; one feature of it being that a prolongation of the tube holding the pumice-stone, beyond the point of exit of the tube carrying the fumes into the water, serves to receive any excess of acid and thus prevent its escaping into the water. The directions should state the strength of the ammonia and acid preparations. The agents are Messrs. J. Carr and Co., Pharmaceutical Chemists, 171, High Holborn, London, W.C.

THE "UNBREAKABLE" CLINICAL THERMOMETER IN PATENT "SAFETY" CASE.

WE consider the patent "safety" case introduced by Messrs. J. C. Fell and Co. (1, Queen Victoria-street, London) a very useful invention. The insertion of the thermometer in its case must be performed by a screwing motion in the direction of the arrow marked on the case. If the attempt be made to insert the glass by direct pressure, considerable resistance will be offered by the indiarubber flanges, and it is difficult then to ascertain when the thermometer is "driven home." Would it not be an advantage to have some means of knowing how "far and no further" the instrument should be inserted?

IMMISCH'S IMPROVED CLINICAL THERMOMETER.

To Mr. Immisch's avitreous thermometer an addition has been made which will be appreciated by clinicians as a distinct improvement. It consists of the introduction of a stop, by means of which the reading can be fixed after the temperature is taken. This object is secured by simply pulling out a knob inside the bow, the reverse action serving again to liberate the pointer.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 12, 1887.

DR. BUCHANAN has submitted a second official report to the Local Government Board as to the proceedings of his department during the year 1885. His first one related solely to cholera; the present one may be taken as his ordinary annual volume, and it deals with many matters of great interest. There is, however, one subject which may be regarded as taking precedence of all others, and that is the question of the influence of small-pox hospitals in London. Ever since the Medical Department of the Local Government Board found themselves confronted by the facts reported by Mr. POWER as to the influence of the Fulham Small-pox Hospital on the area around it, this subject has received a considerable amount of attention both on the part of experts and of the public. Former unbelievers in the influence for evil which the metropolitan small-pox hospitals have exerted have very generally come to see their error, and Mr. POWER'S contention of the mischief produced has been supported and endorsed by some of the ablest of metropolitan medical officers of health. Even those who do not agree as to the method by which the evil is brought about have been unable to deny the facts, but many have sought to reduce to a minimum the inference which it is natural to draw from Mr. POWER'S labours, and to point to side issues which, after all, do not materially affect the principal question under discussion. All the information at present available on the subject is now brought down to current date, and it is impossible to read the carefully considered document which Dr. BUCHANAN has submitted to his Board without being convinced that some radical change in the matter of isolating small-pox patients in urban districts is called for. London has always been liable to an excess of small-pox when compared with the provinces, but, as the report points out, "of recent years a new factor has come into operation." Indeed, it is shown, both by statistics and by diagrams, that, whereas in the provinces there has been a remarkable and almost steady diminution of small-pox mortality during the past ten years, no such reduction has taken place in the metropolis. It is true that improved vaccination in London has succeeded in effecting a great reduction in the small-pox deaths amongst children, but, notwithstanding this, the general small-pox rate remains so high that it is in effect sevenfold that which obtains in other parts of England. What is this new factor? None other than the establishment in London of permanent hospital centres for the aggregation of small-pox cases.

Quite recently a correspondence has been going on in the general press as to this matter, and an attempt has been made to show that even those who now condemn the London small-pox hospitals have expressed opinions to the effect that such hospitals operated for good in urban as well as in rural districts. But the principal opinion quoted was some twelve years old, and the writer who quotes it has apparently forgotten that the science of preventive medicine is progressive. The fact that Mr. POWER and others, who first ascertained the serious evils resulting from the Fulham Hospital, originally entered on their inquiries under a distinct conviction that the mischief complained of would admit of a totally different interpretation, gives special force to the altered views which they now find themselves compelled to express. These views were of such importance that they were investigated at great length by a Royal Commission, which came to the conclusion that by some means or other the London small-pox hospitals all shared the disastrous ability to spread small-pox over the neighbourhoods around them. Since then the investigation has been continued, and, instead of any discovery tending to vitiate this conclusion, the evil has become more and more evident, and it is clear that even the diminished number of acute cases which the Metropolitan Asylums Board decided to retain in London hospitals is capable of spreading small-pox, and this at a distance of a mile over inhabited urban areas. This circumstance is the more important because the mischief is maintained, notwithstanding every effort to control it. Improvements have been effected in the ambulance service, the staff of the hospitals have submitted to restrictions which were not deemed necessary before, and all the incomings and outgoings of the hospital have been placed under a rigid supervision. Indeed, those responsible for these hospitals could, in so far as administration is concerned, hardly have done more. But no effect has resulted; the hospitals, when used for small-pox, still remain centres of infection to the districts around.

We shall recur to this subject of the influence of small-pox hospitals in London when we review Dr. BUCHANAN'S report more in detail. But in the meantime we would note the curious fact that, at the request of the President of the Local Government Board, Dr. BUCHANAN has inserted in his report certain observations made by Dr. BRIDGES, of the Poor-law Department, on the same subject. Indeed, the insertion of Dr. BRIDGES' contribution is apparently intended to minimise the effect of that emanating from the Board's principal medical officer, but, as a matter of fact, it does nothing of the kind. It takes up two points. The first is, Do small-pox hospitals spread disease around them? As to this, Dr. BRIDGES accepts Mr. POWER'S facts, and admits that they "show clearly that a small-pox hospital in a populated neighbourhood has been, with all the precautions as yet devised, an appreciable source of danger to that neighbourhood." But he then proceeds, with the aid of the Registrar-General, to point out that a district which contains a small-pox hospital may possibly have the "benefit conferred upon it counterbalanced by some small disadvantage." As to this, we expect such districts as Hampstead and Fulham would far sooner have faced the "disadvantage" of having no small-pox hospital than have run the risk of such "benefit" as is here referred to. Dr. BRIDGES' next point relates to the question of the conveyance of the small-pox infection atmospherically for long distances. But this is on the present occasion entirely beside the mark, for Dr. BUCHANAN'S report does not deal with this subject at all. His contention is simply that, notwithstanding every effort to the contrary, these hospitals are in some way or other centres of infection, and that

Digitized by Google

their establishment has coincided in point of time with the maintenance in the metropolis of an excessive small-pox death-rate.

We sincerely trust that the atmospheric theory as set out by Mr. POWER may be found to be the true explanation of the evil, for it will then still be open to the Metropolitan Asylums Board to devise means such as were brought under the notice of the Royal Commission for so constructing small-pox hospitals that no infected air shall pass out of them. But if the anti-aerial theorists are correct, then we are in an utterly hopeless state, for "with all the precautions as yet devised"—and Dr. BRIDGES has apparently no others to suggest—the danger still continues. Surely the time has come when, as Dr. BUCHANAN points out, the other means recommended by the Royal Commission for reducing the chance of spreading this infection ought to be tried. The Asylums Board are wanting to spend large sums on small-pox hospital construction at the present moment; we hope that they will be urged to carry out the views of the Commission by the erection of at least one experimental hospital which shall destroy its own infected atmosphere on its own premises. When this has failed, but not until then, they will have done all that the public can at present expect of them.

IN our last number we pointed out that the optimist conclusions with regard to the past and future of the University of London set forth in the current number of the *Quarterly Review* required very considerable modifications when examined from the point of view of the other Faculties, and we shall now show that even from a medical standpoint the results are not so wholly favourable as the writer would have us believe. No one conversant with medical studies and medical examinations during the past ten or twenty years will endorse the following opinions of the writer of the article: "It is probably in Medicine that the influence of the University of London has been most powerfully felt, and that its most conspicuous successes have been achieved. . . . . It is generally admitted that the requirements of the University have done much to encourage those higher studies and researches on which the advancement of pathological and therapeutical science most depends." Criticism of such dogmatic assertions as these is difficult, as they are obviously written without due appreciation of the means and methods by which medical science has been making such rapid strides in late years. When the University of London instituted degrees in Medicine, and raised the standard of professional and general examination, all the ambitious *alumni* of the London and provincial schools naturally endeavoured to obtain the newly made and coveted degree of M.D. Lond., and this movement went on for some thirty years, because degrees elsewhere were only to be obtained by compliance with onerous restrictions as to residence which London students could ill afford to yield. The examinations and regulations of the University of London, although stringent, were then really much less severe than those which are insisted on at the present time, and the required period of study was not nearly so protracted or attended with such great expense. The Senate, being practically a body into which only the least possible change can be introduced, looks but little at other educational institutions, and clings to the belief that all modern improvements in medical education and examination are due to the example and influence of Burlington Gardens. But in the last twenty years a great alteration has come over the spirit of medical work and responsibility throughout the kingdom, whilst the authorities of the University of London have done little or nothing to assist therein, one guiding consideration alone influencing their conduct—that to increase the stringency of its examinations was the *raison d'être* of its existence and the proof of its utility. Other Universities have enormously developed from a teaching standpoint, and have increased the number of their students; biological and physical sciences have been fostered and encouraged by them; their degrees have acquired a greater prestige in the eyes of medical students, and candidates from all schools outside the metropolitan range have been attracted to Cambridge and Manchester, until now a very insignificant number of the total body of students are to be found amongst London medical graduates; and yet the University of London is satisfied. It does not see that under its present arrangements it is fast losing its pre-eminence. "The University has probably influenced the profession profoundly and beneficially by confining its distinctions to the *élite* of medical students, and by setting up a high ideal of professional qualification. It may be doubted whether an equally useful object would have been attained if it had admitted ten times the number on easier conditions." We very much question whether it is now attracting the *élite* of the profession, and we are quite sure that it could have been much more influential by not ignoring the teachers and without any real lowering of its standard. Out of 800 students in the London medical schools only 36 obtained the qualification of M.B. last year, and 42 is the average number for the past eight years. Is this a satisfactory result after fifty years of existence? We venture to say that the result is most unsatisfactory, and that many men equal in intellectual calibre, and in many respects superior in professional acquirements, to those who have obtained a London degree, have been stopped at the threshold by the undue severity of its first two examinations, whilst the prohibitive regulations of its later ones and the length of time and cost involved in carrying out the curriculum, have deterred many others. The Senate must not conclude that it collects within its net even all the abler London men; it is well known that for many years past this has not been the case, and our columns last week afford a striking example. One candidate only out of 11 who are competing for the vacant assistant-physiciancy at St. Bartholomew's Hospital is a graduate of the University of London. In 1863 the degree of M.S. was instituted, and we have, after twenty-three years, just 16 graduates who have passed the examination for its attainment. Most of these are also Fellows of the College of Surgeons, and have passed as stringent a professional examination for this honour as for the University degree. The institution of this degree in Surgery is therefore evidently not a success. Out of 14 examiners in medical subjects in the University itself, only one-half are graduates of the University, and of 12 external examiners appointed at the Victoria University only 3 are London

Digitized by Google

graduates, clearly showing that in medical science experts are largely found among graduates of other Universities. We believe that in a few years we shall see a further displacement of London graduates in the London teaching schools by those who, having been clinically educated in London, have sought degrees elsewhere. The *Quarterly* reviewer, whilst pointing out the desirability of a federation of the medical schools in London, says that this could not be enforced by any external authority, and could be adopted at once without waiting for a reorganised University to suggest it. This is undoubtedly quite true, but he overlooks the consideration of the assistance which an external authority like a University would be able to afford to such a movement, and we hope we may yet see a real University in London with a medical faculty under the care and guidance of the Royal Colleges of Physicians and Surgeons. The constitution of the Senate of the University of London, composed of "men of eminence in literature, in science, and in academic and public life," must be completely altered before it will pay any heed to the needs of teachers or students. It has quite lost touch with these, and its foremost considerations are given to shaping the "conditions of its examinations." For these only it exists, and to these its satisfaction is limited.

IT would seem to be possible, if not probable, that the session of Parliament now in progress will be distinguished by the passing of a Bill to consolidate and amend the Lunacy Acts. At present the Lord Chancellor's scheme has been embodied in two Bills, for the convenience of discussing the new proposals apart from the technical business of consolidating those provisions of the existing Acts concerning which there is no question. Hereafter the two Bills are to be combined; but meanwhile it must not be assumed that the Consolidating Bill contains no new and important amendments. For example, it makes the appointment of a resident medical officer essential in the case of every asylum having fifty patients. This enactment does not affect existing institutions, as the practice has outrun the law; but the substitution of fifty patients for one hundred as the limit is a notable amendment; and other changes not less significant, though more effective, will be found on close scrutiny. The Consolidating Bill will need to be carefully studied and watched.

The provisions embodied in the amending Bill are explained in a memorandum accompanying the measure as presented to the House of Lords, and are generally described as carrying out "in the main the recommendations made by the Report of the Select Committee on Lunacy Law in the year 1878," which committee, it will be remembered, the community owes to the persistent enterprise of the member for Swansea, Mr. DILLWYN. We are not able to say that the Bill as it stands is all that could be desired; but it certainly sets forth changes to be made in the law which will have the threefold effect (1) of rendering the treatment of sane persons as lunatics increasingly difficult and therefore less probable—it would be well if we could say impossible; (2) of protecting from vexatious proceedings those who have to assume responsibility in the placing of alleged lunatics under control, although in this respect the provision relates rather to the arrest of proceedings than to their prevention; and (3) of preventing the multiplication of private asylums, albeit those which exist are to be allowed to carry on their business, and any number which may be in process of establishment at the time of the passing of this Act are also to be tolerated. It is to be regretted that the rights of property, however admirable in their way, should be deemed an insuperable obstacle to the summary sweeping away of a system which is bad in principle, and admits of no defence. The change to be immediately accomplished consists mainly in the elaboration of measures whereby the now facile process of placing an alleged lunatic in confinement is to be complicated and brought under official cognisance. The main defects of the method by which this is to be done lie in details which can be modified in committee.

Speaking broadly, it may be said that the chief points gained by the reformers at whose instigation this passably liberal measure has been wrung from the Government is, that henceforth the hole-in-corner proceeding by which it is now easy to put away any weak-minded or eccentric person in an asylum as a lunatic will be, in a perfunctory and permissory fashion, brought under the cognisance of a County Court judge or a justice of the peace, who may, *if he see fit*, or if the victim of the proceeding has the wit and is able to get at the magistrate, bring about a personal interview between the alleged lunatic and the functionary appointed to protect him. What would be thought of a provision to the effect that if the judge thought fit, or a prisoner demanded it, the accused might be present at his own trial? Nothing probably will convince those who look upon the victims of mental disease as wild beasts from whom the sane are to be protected at all costs and risks that even a reputed madman has his rights. After the passing of this Act, also, it will be possible for persons to be placed under treatment of their own volition. This is a most important and useful provision. Moreover, there will be a system of visiting and reporting upon the cases of persons who are confined as lunatics, which, if only what is now permissory can be made obligatory, and some way can be devised of compelling the authorities to discharge their duty quickly as well as efficiently, will be advantageous.

We are not greatly interested to discuss the details of the Bill at this stage—first, because they have been again and again discussed, *usque ad nauseam*, in both the professional and the lay press; and second, because unless or until the measure reaches the House of Commons it cannot be held to be actually on its trial as a practical proposal. There has been so much trifling with this question of Lunacy Law amendment, that even those who regard the proposal as a threat of "wolf" have ceased to tremble at the cry too often raised in vain; while for the majority—who earnestly desire the sweeping away of a vicious system—the truckling to vested interests, and the blighting influence of officialism interfering, with the effect of taking the heart out of every measure of reform and reducing what were once spirited proposals to mere puny changes of name and form, the vexatious delay and trifling which have characterised this matter throughout its progress have proved so disappointing as to give rise to a feeling of disgust with the whole business. Hereafter it may happen that interest may be re-

Digitized by Google

awakened by the development of a measure which at the first blush appears to be a curious crowding of elaborate detail into a crude and confined outline. Precisely that which might be expected to result from the meddling and muddling of many interested persons working together under the anxious supervision of a timid Minister, morbidly solicitous to please the majority and give serious offence to no one, this Bill certainly is. It is not possible that it should ever be a thoroughly satisfactory measure; but, on the principle that half a loaf is better than no bread, we may yet learn to take it and be thankful. Some of its provisions, if not ridiculous, are grotesque. Thus those who are wont to be thankful for the very smallest of mercies may find consolation in the proposed enactment by Sub-section 2, Section 8, that a lunatic shall not be sent to an asylum upon the *medical* certificate of his mother-in-law; but it does seem strange that, as Lord HALSBURY manifestly contemplates the rapid rise and extensive practice of feminine physicians, he has not, while protecting a lunatic from his mother and mother-in-law, also provided for his safety against the machinations of his grandmother!

As we reported in our columns last week, Professor HAMILTON of Edinburgh has recently propounded his views on some points in the anatomy of the brain, which he has studied by means of enlarged sections of the organ prepared by a special method of his own. And first, with regard to the corpus callosum, he still adheres to the view which he put forward at the Royal Society of London in the year 1884. This theory is a modification of that originally advanced by FOVILLE. It argues that the fibres which compose the corpus callosum are really derived from the basal ganglia, and pass upwards towards the cerebral cortex along the fibres of the internal and external capsules to the opposite side of the brain. We think this notion is inherently improbable. Further, it is based on a method of examination which, to say the least, cannot be regarded as altogether satisfactory. The method is that of naked-eye examination, or aided by the use of a lens, of the enlarged and prepared sections. The more careful method adopted by Dr. BEEVOR and the experiments of Mr. VICTOR HORSLEY are apparently directly opposed to the conclusions of Dr. HAMILTON. In the October number of *Brain* for 1885, Dr. BEEVOR gives the results of his investigations of sections stained by WEIGERT'S method, so prepared as to exhibit the medullary fibres. This method demonstrated that the fibres of the corpus callosum and those of the internal capsule interweaved with one another in their passage to the cerebral cortex. He could not discover any direct communication between the fibres of the capsule and those of the corpus callosum. Mr. VICTOR HORSLEY, in the last series of the Brown Lectures, explained that when the whole motor area of the cerebral cortex of one side in the monkey was extirpated, stimulation of the remaining motor area was not able to evoke cortical epilepsy of the limbs of the same side of the body as the cortex stimulated, showing, with other experiments apparently conclusively, that the fibres of the corpus callosum conveyed stimuli to the opposite cortical motor centres. The same experimenter's observations on the division of the corpus callosum in animals pointed to a similar conclusion. As to Dr. HAMILTON'S plexiform nucleus having a correlatin function situated internal to the upper part of the interna capsule near the lenticular nucleus, we can only say tha it is altogether at variance with our present notions, for i would appear to be an axiom of cerebral physiology tha a creating or a correlating function cannot take plac in the absence of nerve cells; and, if our information b correct, Dr. HAMILTON assigns such a function to a mer aggregation of fine nerve fibrils. The optic thalamus is an has been a crux to experimental and clinical pathologist for all past time. We are much indebted to him fo attempting to throw light on this most obscure subject He believes that this body is a communicating centre o association bringing the functions of sight into relatio with those of other cerebral functions. It may be so; bu such a view rests on scarcely any other basis than that o mere opinion. We cannot but think that his theories as t the relation of nerve cells and fibres are also diametrically opposed to the doctrine of continuity of structure and function. We have only the report, necessarily brief, of the meeting of the Edinburgh Royal Society to guide us. But we cannot think he is right in doubting that nerve fibres enter nerve cells, unless in the motor areas. Must we suppose that Dr. HAMILTON believes that the capsular network of fibrils which surrounds the nerve cell, but does not come into actual structural relationship with it, acts after the fashion of induction of one current on another, as in faradisation? Although we are unable to concur with Dr. HAMILTON in all the conclusions at which he has arrived, we must allow that he has displayed considerable ingenuity in his views, and has contributed largely to our practical methods of investigating the anatomy of the brain.

WE have already pointed out that the Medical Council that is to sit on Tuesday next will be largely a new body. Fully a third of its members are either new or sit for the first time in new capacities. The profession at large will have its representatives, and several Universities which have hitherto had but half a representative, or one representative between two Universities, will each have a member of the Council all to itself to defend the individual interests of his own institution in that subtlest and most pleasing of all ways —by showing that the harmony and general welfare of the universe are only to be maintained by preserving intact all its emoluments and privileges. We cannot of course say what the exact nature of the duties of this reformed Council will be at its approaching sitting, but we may be sure that it will have some new duties to discharge, arising under the very imperfect Act of 1886, as well as various duties of the old type. The clauses of the Act which create fresh duties for the Council are chiefly two. Clause 2, Section 3, declares that it shall be the duty of the General Council to secure the maintenance of such a standard of proficiency at the qualifying examinations as shall guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery. Not only so; it specifies a new and special means by which this duty of the Council is to be discharged:—

"For that purpose (securing the maintenance of such standard of proficiency as aforesaid) such number of Inspectors as may be determined by the General Council shall be

Digitized by Google

appointed by the General Council, and shall attend, as the General Council may direct, at all or any of the qualifying examinations held by any of the bodies."

In a subsequent paragraph, Section 3, the duties of these inspectors are defined. They are to report their opinions on the sufficiency or otherwise of examinations. Moreover, they are to report as to any other matters in relation to such examinations on which the General Council may require them to report. This is a large sentence, and may be used to make the reports of inspectors cover much. The bodies reported on are to receive copies of such reports, and so also is the Privy Council, which is further to be supplied with the answers of the said bodies. Clearly, then, the appointment of Inspectors under the recent Act is a most important—perhaps the most important—duty that can engage the attention of the Council. The duty of considering and reporting on this question in a preliminary way was entrusted to the Executive Committee, from which a report may be expected. It is of great moment that efficient men should be chosen for this duty of inspection. The words of the Act show that its framers look to inspection as the chief means of securing the general efficiency of examinations. And it is to be fondly hoped that no narrow fields or territorial restrictions will limit the purview of inspectors. We want, above all things, fair play and sound work in every division of the kingdom. We want a cessation of international suspicions and disparagements. We want the Corporations to respect the examinations of the Universities, and the Universities not to despise the examinations of the Corporations. The inspectors are expected to achieve these results, and they should be men to whom the profession and the examining authorities will look up.

Other new duties will arise under the second part of the Act, referring to the registration of *Foreign* and *Colonial* qualifications, and a report of the Executive Committee on the subject may also be expected. Further new work has been made by the recent Act not only for the Medical Council, but for all the examining authorities, in Clause 21 of Part III., which provides for the registration of diplomas in Sanitary Science. The examining bodies may all be expected to respond and to ask recognition of their examinations in Preventive Medicine. Besides these subjects, there will doubtless be a score of others to exercise the new Council and to tempt the eloquence of its members.

We bespeak, for the sake of our reporters and of our readers, speeches short and to the point. It is hard to hope that a Council of thirty or more will work better than one of twenty-four. The scheme of THE LANCET for a Council of twelve is still unrealised, as is the one-portal system of all medical reformers and even of the Council itself. Let us, however, whilst hoping against hope, give the Act of 1886 a fair trial.

On the 3rd inst. Mr. Ritchie, in reply to a deputation from the National Society for the Prevention of River Pollution, stated that the Government intended to give to the County Boards, which they hoped to establish, the power of dealing with the question of river pollution, and it was hoped that this would meet the requirements of the case; at any rate, the Government would not be inclined to go any further until the County Boards Bill had been passed and its operation tested.

Annotations.

"Ne quid nimis."

THE PUBLIC HEALTH IN 1886.

FOLLOWING closely upon the Detailed Annual Report for 1885, the Registrar-General has just issued, in his quarterly return for the three months ending with December last, a summary of the national vital statistics for 1886. The birth-rate of England and Wales was last year equal to 32·4 per 1000 of the estimated population, and no less than 2·0 below the mean annual rate in the preceding ten years; it was lower than in any year since 1848, when the registration of births is known to have been very incomplete. The death-rate of the year, notwithstanding the exceptionally trying weather in the first quarter, and a more than average warm summer that caused excessive mortality from infantile diarrhœa, was so low as 19·3 per 1000, corresponding with the mean annual rate in the preceding five years. Thus the mean death-rate in the first six years of the current decennium (1881-90) was equal to 19·3, and was 2·1 below the mean-rate in the preceding ten years 1871-80. The Registrar-General points out that this remarkable decline in the death-rate "implies that more than 339,000 persons in England and Wales were alive at the end of the six years (1881-86) whose deaths would have been recorded had the mean rate of mortality equalled that which had prevailed throughout the preceding ten years." Nearly half this reduction in the death-rate in recent years was due to decreased zymotic mortality, for it appears that the death-rate from the principal zymotic diseases, which was equal to 4·15 and 3·40 per 1000 respectively in the two decennial periods 1861-70 and 1871-80, further fell to 2·43 in the six years 1881-6. Compared with those recorded in 1886, the deaths from diarrhœa last year showed a considerable increase, and those from "fever" were rather more numerous, whereas those referred to each of the other zymotic diseases showed a decline. The death-rate from scarlet fever was considerably lower in 1886 than in any previous year on record, and has fallen year by year since 1878. Fever (typhus, enteric, or simple) mortality has been equal to an annual rate of 0·26 per 1000 in the past six years, whereas the rates in the preceding three decennial periods were 0·91, 0·89, and 0·50 respectively. Only 284 fatal cases of small-pox were reported in England and Wales in 1886; the nearest approach to so low a number, recorded in any previous year since civil registration commenced, was 536 in 1879. On the whole, this brief summary of the vital statistics of 1886 supplies a measure of the public health during last year which is full of the strongest encouragement to sanitary effort, of which the present satisfactory bulletin is undoubtedly the result.

THE DARENTH HOSPITAL DISPUTE.

THE *Metropolitan*, in discussing a recent article in THE LANCET on the reasons for the opposition which has been raised to the construction of brick hospitals at Darenth, states, as one of these reasons, that medical knowledge increases with every epidemic, and with the help of advanced sanitation is reducing the virulence of small-pox. Certainly, as the value of vaccination and revaccination is better understood, it may be anticipated that small-pox will be less prevalent in the metropolis; but, apart from this, we fear that London will continue to be visited by epidemics, which will make the existence of a hospital at Darenth or elsewhere a necessity for very many years to come. We fail, indeed, to understand the position either of the Metropolitan Asylums Board or the Local Government Board in the course they have adopted as the result of the controversy. The

Digitized by Google

managers, in seeking to erect a permanent brick structure, were doubtless acting in accordance with the dictates of their experience of the great cost incurred in the maintenance of temporary erections. The Local Government Board, in their turn, had but too much reason for objecting to the construction of such a hospital on similar lines to those which have proved so disastrous to the metropolis. But the bargain which has been struck between the two authorities is distinctly ludicrous. The managers adhere to the use of brick, and the Board assent on the understanding that the hospital is not permanent; that is to say, the managers can now assert that the hospital is to be temporarily permanent, while the Board can plead that it is to be permanently temporary, or, in other words, they agree that the brick hospital is to be so badly built that it is warranted to fall into decay within a short period. It is clear that the speculative builder can urge that high authorities have justified his existence. The greatest hope for the reduction of small-pox in London is the present arrangement, which removes to a distance from occupied houses the majority of all persons suffering from this disease, and the aggregation of the few cases which must remain in London, under the conditions indicated by Dr. Buchanan in the report which the Local Government Board have just issued.

THE UNIVERSITY OF EDINBURGH.

THE prosperity of the University of Edinburgh continues and increases, especially in its Medical Faculty. Last year its matriculated students numbered 3635—110 more than the previous year. Of these, 1915 were in the Faculty of Medicine. In this faculty 51 candidates took the degree of M.D. and 229 the combined degrees of Bachelor of Medicine and Master in Surgery. This prosperity is attributed largely to the excellent appliances of the new University buildings. Private benefactions are always testifying to the gratitude and affection of wealthy or willing Scots, who are proud of their Universities, which have done so much for them and their countrymen. Several have been received in the last year; and one large donation is expected, to the amount of £50,000, from a public-spirited citizen of Edinburgh, which is to take the shape of a grand Academic Hall. The Fancy Fair in December, initiated by the students, proved a great success, and something like £11,000 were raised. When will London feel the true fire of this academic pride? When she does, with her superior resources and her splendid *clinique*, Edinburgh may begin to fear; but she must be in earnest, and have a real University that can win the admiration of all sorts of intellect and the gratitude of all classes.

PNEUMOTOMY IN PULMONARY ABSCESS.

DR. RUNEBERG, Professor of Medicine at Helsingfors, in a clinical lecture which has been published in a Swedish journal published in Finland, gives an account of a case of pulmonary abscess consequent on acute pneumonia, where he had performed pneumotomy with success. In addition to this he had collected notes of ten other cases. Leaving aside three of the eleven on account of uncertainty in the diagnosis, five of the remaining eight recovered, or at all events improved very decidedly, and in the rest, which were fatal, death could not in any way be attributed to the operation, so that Dr. Runeberg considers that when the diagnosis of pulmonary abscess is clear, and it is in an accessible situation, the best practice is certainly to open it. He then refers to the question of operating for gangrene of the lung. He himself had had a case of this, together with bronchitis and bronchiectasis; after the operation secondary gangrene and septicæmia occurred, which proved fatal. In seventeen other cases of gangrene he quotes from medical literature where pneumotomy was performed, seven recovered more or less completely, and the fatal termination of the remaining ten did not appear to have been attributable to the surgical interference. As to the method of opening the lung, Dr. Runeberg is in favour of resecting a rib, and then using the thermo-cautery. He does not approve of washing out the cavity with antiseptic lotions, thinking them dangerous, and believing that ample drainage is sufficient. In conclusion, he mentions several pneumotomy cases he had collected: two were for ecchinoccocus, both terminating favourably; six were for bronchiectasic cavities with gangrene; and six for tubercular cavities. In the latter two classes of cases he does not think operative procedures are advisable.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

A SPECIAL conference between the Council of Hospital Sunday Fund and the managers of the various hospitals was held on the 9th inst. at the Mansion House, the Lord Mayor presiding. The following resolution was carried unanimously: "That with the view of largely increasing the Fund to be contributed on Hospital Sunday (June 19th) for the support of the hospitals and dispensaries of the metropolis, a series of public meetings be held during the two weeks preceding Hospital Sunday, and that the members of the committees of the several hospitals and dispensaries be requested to co-operate with the Mansion House Committee in organising these Jubilee Year meetings in their respective localities." The Lord Mayor will preside at a meeting arranged to be held in the Egyptian Hall, Guildhall, on behalf of the Metropolitan Hospital Sunday Fund, on June 14th, at 2.30. P.M. The meeting was originally fixed to take place on Wednesday, June 15th, but has been altered as above for the convenience of Lord Salisbury, who wishes to move the first resolution. It is expected that Lord Granville, Cardinal Manning, Canon Fleming, and many others will be present and take part in the proceedings. The London bankers and leading merchants will be specially invited to attend by the Lord Mayor. This meeting, taking place within five days of the Sunday (June 19th) on which the collection is made, should have a most favourable effect upon the amount received. We may here mention that Ernest A. Hankey, Esq., has recently contributed the sum of £495 to the Fund for this year.

DEATH BY FIRE ON RAILWAYS.

THERE can be no question as to the inexpediency of lighting railway carriages with swinging lamps burning petroleum. The risk is manifestly so great that it is inexplicable that a nation so advanced and enterprising as the American should tolerate it. The only hypothesis, which, indeed, is supported by other anomalies in the social life of that great nation, would seem to be that, however ingenious and go-a-head the Americans have shown themselves, they must be at heart a *young* people with the recklessness as to life which distinguishes the youth of communities, just as heedless daring is a characteristic of the young individual. Just outside the boundaries of strictly city life the American carries his revolver and uses it without scruple, as the juvenile employs his fists or a stick. So it is with the enterprise of this rapidly-growing people: everything must be very "big," and very "tall," and very "grand," and all risks, rational and irrational, must be dared in making it. We of England may be perverse and fatuous in the imbecility of our second childhood, but we are not quite such fools as to heat our railway carriages with swinging lamps of petroleum or by stoves. Our stupidity comes out in not heating them at all. It is quite useless trying to point the moral of the recent terrible catastrophe

Digitized by Google

which has caused a deplorable loss of life on the Vermont Central Railway. There is nothing to be said on the subject, except that it is not less a senseless than a deplorable occurrence. Death by fire on railways can but very rarely be classed as "accidental."

TUBERCULOSIS OF THE ŒSOPHAGUS.

AT a recent meeting of the Medical Society of Vienna (*Progrès Méd.*, 1887, No. 6, Vienna Correspondence), Dr. Zemann, assistant to Professor Kundrat, read a paper on tuberculosis of the œsophagus, of which he distinguished four different forms. In the first the affection is propagated by direct extension from the bronchial glands or the lungs. In these cases the gullet may be perforated by direct ulceration, and frequently the contiguous portion of the trachea or bronchus is subsequently perforated; or the ulceration of the œsophagus may arise from tubercular deposit in its anterior wall. In the second variety the mucous membrane of the œsophagus is invaded by extension of tubercular disease of the pharynx or larynx, producing superficial ulcers which are limited to the upper third. Instances were given of a still further propagation of the disease in the œsophagus in two patients who were suffering from strictures of the tube from corrosive poisoning. They were also the subjects of tubercular phthisis, and although the larynx and bronchial glands were free, yet caseous and yellow tubercles were found in the cicatricial tissue in the œsophagus. Bacilli were detected in these tubercles. The explanation evidently lies in the fact that ordinarily, from its thick epithelial lining, the œsophageal mucous membrane is protected from bacillary infection, and a protection which is destroyed by the action of corrosives. In both the cases, it should be added, intestinal tubercle was present. The third variety is acute miliary tuberculosis, of which, however, only one case is on record—viz., by Marotti. The fourth variety, also of great rarity, is infection of the œsophagus by sputum; a condition probably only produced when the epithelium is more or less detached.

THE NON-REGISTRATION OF STILLBORN INFANTS.

A CORRESPONDENT has sent us the "return" required by the Brooklyn Board of Health in the case of every stillborn infant born within the district. How complete this return is may be inferred from the fact that there are no fewer than sixteen items to be filled up. In addition to the more obvious ones of sex, parentage, place and date of birth, name and address of medical attendant, and cause of stillbirth, we observe that the "nativity of father and mother" is required, also the name and residence of the person making the return, those of the undertaker, and the place of burial. The importance of all these details, which, more or less modified, are required in almost every civilised country except Great Britain, will be appreciated by all who have had much obstetric practice or have interested themselves in forensic medicine. Obstetric practitioners know that while a certain proportion of stillbirths are inevitable from causes both known and unknown, a very large number are preventable, being caused by want of proper attendance before and after birth, syphilis in one or both parents, neglected or inefficiently treated, and other causes. The exact determination and classification of these would be sufficient to justify the notification, if not the registration, of all stillborn infants in this country. But there are other reasons equally strong from the medico-legal point of view. It is well known that most burial authorities adopt a sliding scale of charges for the burial of newly-born infants, the difference between those for a stillbirth and those for a deceased infant being from 1*s.* 6*d.* to 7*s.* 6*d.*—a great consideration to poor people, and a strong inducement to them to make false declarations. If this sliding scale could be abolished and one uniform charge made for all infants stillborn or deceased within twenty-four hours after birth, this inducement would be lessened, if not removed altogether. But, besides this, it is imperative that there should be a register kept and returns made periodically of all bodies interred as stillbirths in every public burial-ground. A printed form of certificate should be issued by the Home Office or the Local Government Board, which should be distributed to all medical practitioners, and these as they are presented at the burial should be carefully preserved. It is, to say the least, an anomaly that, while the birth and death of a premature infant born at the seventh month of utero-gestation are each registered as solemnly as the death of the "oldest inhabitant," the State takes no heed of the many infants born dead at full time.

THE LESSON OF THE "KAPUNDA" DISASTER.

AFTER the sad teaching of experience in the case of the *Kapunda*, we may perhaps expect that the safety of passengers on board ship will be more carefully provided for than it was in this instance. As usual, after an event of the kind, suggestions are numerous as to the best means of guarding against a sacrifice of life by such a disaster in the future. Boats, folding-boats, floating seats, life-belts and buoys have figured prominently in the newspaper correspondence on the subject during the last few days. There is no want of possible appliances apparently, and there are no doubt shipping companies willing to spend freely upon them in order to assure as far as may be the safety of their crews and passengers. Still the uncomfortable fact remains that such assurance cannot always be relied on, nor is it likely to be otherwise while the law upon this subject remains as at present—notably inefficient. It is not enough to entrust a matter so serious to the private judgment of individuals. The Board of Trade already exercises a jurisdiction in such cases, and it ought, in order to justify its action, to afford to every passenger, and not only to a limited number, the means of self-preservation in case of shipwreck.

THE DIPHTHERIA EPIDEMIC AT EALING.

THE outbreak of diphtheria at Ealing, to which we called attention in our last impression, has unfortunately proved more severely fatal than was at first hoped. We referred to three deaths which occurred in the first five days of the outbreak, but we now learn the fatality went on until the record has reached eleven. The attack was singularly sudden in its appearance, and seems to have been as sudden in its cessation. Its actual course has been apparently confined within the limited period of seven days, but, as Mr. Patten, the medical officer of health for the district, reported to his board, the fatal cases were in every instance confined exclusively to persons who were the first to exhibit symptoms of the disorder, and upon whom the virulence of the poison appears to have been expended. We are glad to learn that Mr. W. H. Power has received instructions to make an investigation into the circumstances connected with the outbreak of diphtheria at Ealing. There are certain characteristics of the outbreak which are etiologically of considerable interest, and a Government inspector has special facilities for extending his inquiry beyond any defined sanitary areas if he finds reason to suspect that the cause of a disease lies outside those limits. An unanswerable exposition of the cause of the catastrophe at Ealing may be of lasting value to the whole country, and for the matter of that to the whole world. It was a deliverance of an authority not less illustrious than Sir Isaac Newton himself that no more

Digitized by Google

causes of a phenomenon ought to be admitted than such as are true and sufficient to explain the phenomenon, and the problem in this case is how to get at the true and sufficient cause of the outbreak. Under present circumstances the cause cannot be very deeply concealed; whatever it may be, it is a cause which has operated chiefly among the well-to-do classes. It has been introduced suddenly; it has departed speedily. Taking the incubation period of diphtheria at three or four days, we may almost determine the day when the cause entered Ealing—namely, about Jan. 17th or 18th. If it had come in by water-supply, we must assume it would have affected large numbers of people irrespectively of class. If it had come in from drainage, it would most likely have affected the poorer classes rather than the richer. If it had been an atmospheric cause, it would surely have been equally distributed. If it had spread from one case to another simply by contagion or infection, it would have been traceable from one centre in definite lines. The evidence therefore points to the cause as entering through some particular article of food or drink, of which a limited number of susceptible persons partook within a very few days, perhaps hours, of each other.

SOME CHOLERA STATISTICS.

THE municipality of Marseilles has issued statistics concerning the second and last cholera epidemic which are not without interest. The number of deaths from cholera in 1884 amounted to 1781, or 4·94 per 1000 of the population. In 1885 the epidemic was not so severe; there were 1256 deaths, or 3·49 per 1000 inhabitants. During the course of the latter year the municipality organised twelve ambulances in different parts of the town, where assistance could be obtained at all times of the day and night. In this the authorities were supported by a staff of 102 doctors, 28 medical students, and 87 dispensing chemists. The total number of patients treated by the members of this service amounted to 2017, of whom 1513 were suffering from cholera. Of the remaining 504, the greater number were suffering from typhoid fever; then came, in order of frequency, cases of hæmorrhage, nervous complaints, pulmonary affections, wounds from accidents, and, above all, derangements of the digestive organs and a few cases of manifest drunkenness. Taking the cholera cases only, the males numbered 871 and the females 607. In 35 instances the sex was not indicated. This proportion is analogous to that noticed in 1884. The ages are given in all excepting 169 cases, and we find the division to be as follows: From the period of birth to the age of twenty there were 223 cases of cholera; from the ages of twenty to fifty there were 813 cases, and only 129 from fifty upwards; under the age of ten there were only 53 cases. It appears, therefore, that cholera proves most fatal in the prime of life. The nationality of 1438 patients was ascertained. There were 1081 French subjects, 272 Italians, and 85 persons belonging to various other nationalities. This shows a very great increase in the foreign elements, and helps to confirm the theory that the crowding together of the poor Italian labourers who flock to Marseilles is one of the most evident causes of insalubrity. During the epidemic of 1884, in the single district of the Bourse, out of 694 cholera patients no less than 242 were Italians. The statistics with regard to the professions of the sufferers unfortunately only refer to 798 patients. By far the greater proportion were unskilled dock labourers or navvies; these numbered 376. After this 94 cases are entered as without profession, 57 as domestic servants, 44 as charwomen, 23 sailors, 25 clerks or shop assistants, and smaller numbers as belonging to various other callings. From these statistics, though referring to only 798 out of the 1513 cases treated, it seems fairly demonstrated that those who came specially in contact with the cholera did not suffer conspicuously more than the rest of the population. But the men who were employed to bury the dead, to disinfect the houses, and to clean the sewers, and the whole of the medical and nursing staff, enjoyed remarkable immunity. It may be added, in conclusion, that the entire cost of the twelve ambulances and hospitals which supplied medical assistance to the 1513 cases amounted to £1641. For medicine and medical advice the actual outlay did not surpass the average sum of 12*s.* 6*d.* each case; but much gratuitous advice was given to the poor.

HOSPITAL SATURDAY AND THE CONTRIBUTIONS OF WORKING MEN.

WE have always felt, and candidly expressed a feeling of, regret at the inadequate collection for the hospitals of London made by its workmen on Hospital Saturday. With equal candour we have insisted that the only way to secure a fit contribution from workmen was to organise a weekly subscription. Something less than the price of a glass of beer would do it. An actual case in point is reported in the *Sunderland Daily Echo* of Jan. 24th, in a notice of the death of a local man of great worth, the late Mr. John Armstrong, of the firm of Armstrong, Addison, and Co., who is credited, amongst other good and sound work, with being the first to carry out the workmen's weekly subscriptions to the Sunderland Infirmary, which have become one of the chief sources of revenue. In the report for 1861 such subscriptions are mentioned as amounting to £45. In the following year they amounted to £200. In 1885-6 they had reached the creditable sum—in this town, whose whole population does not equal that of a large London parish, and in a time of great local distress—of £2000. All honour to such men as Mr. Armstrong, and to the working classes of Sunderland for following his lead and supporting the very best of their local institutions.

CASUAL WARDS.

THE condition of casual paupers requires serious attention, since it is possible that no more wretched set of creatures exist anywhere. Dragging out miserable existences during the day, at night they are housed in lonely dens hardly better than dog kennels, if fate keeps them in London; or if they take refuge in the country workhouse, in outhouses provided with a few sloping boards for beds. For food, a piece of bread and a basin of skilly serve for supper and breakfast. For this entertainment, however, the guest has to pay a somewhat high price, even calculated at the present low rate of wages, by having to perform a considerable amount of manual labour before he is allowed to proceed on his way and find work to support himself. Occasionally he finds that, having entered the casual ward with a light heart, he is not permitted to leave it, even supposing his daily task to have been performed, and he is constrained to remain, against his will, over the coming Sunday. Such an excess of hospitality is not, however, always well received; and the other day a "casual," much to the surprise of the workhouse authorities, refused to return to his "cell," preferring, as he said, the prison to the casual cells on Sunday. It appears that the prisoner had applied for admission on a Friday night at St. George's Workhouse, Westminster. On Saturday morning he was called out and set to work in the yard. The task given him he accomplished quietly and well, and expected the usual discharge. Instead of this, however, he was told to return at once to his cell, as no "casual" was allowed to be out on a Sunday, and as he had come in on Friday he must remain till Monday. In answer to an inquiry by the magistrate, the master informed him that according to the rules of the New Model Workhouse, the

Digitized by Google

"casual" is locked up and kept in solitary confinement all Sunday, without exercise, but with the option of attending a short mission service of an hour's duration. In this case the prisoner had not been informed of the rule when admitted, and refused to return to his cell when requested. In consequence he was removed to the police station, where he spent his Sunday, let us hope more cheerfully than in the workhouse cells, and was discharged by Mr. D'Eyncourt on the Monday morning. Comment on such a case is hardly needed. Nothing was said against the prisoner's character or conduct; he was simply an artisan out of work. Whilst in the workhouse he behaved properly, and the authorities admit he fulfilled his tasks "very quietly and well," and yet this man is arbitrarily seized and threatened with solitary confinement and imprisonment for twenty-four hours for no offence whatever except that he came to the workhouse on a Friday instead of any other night of the week. Severe measures no doubt are required to prevent imposition and idleness, but to act in this outrageous manner to every casual who seeks shelter for a night is certainly, to put it mildly, unnecessary.

THE COURSE OF THE POSTERIOR ROOTS OF THE SPINAL CORD.

DR. ANDREAS TAKÁCS gives the following summary of the results of his investigations in regard to the course of the posterior roots of the spinal nerves and the composition of the white matter in the posterior columns of the cord. 1. The fibres of the posterior roots on their entry into the spinal cord divide into two groups; one part penetrates the grey substance, whilst another group run externally and internally into the white substance bounding the grey horns. 2. The fibres which penetrate the grey horn appear to traverse the substantia gelatinosa, and may be followed to the ganglionic column of Clarke, in the cells of which they terminate. 3. The fibres of the posterior roots, which enter Burdach's column internally and the posterior part of the lateral column externally, immediately bend upwards and run at least as far as the third root above, where they penetrate the substance of the posterior horn. 4. Part of the fibres arising from the cells of Clarke's column dip into Burdach's column, and, after assuming here a wing-like aspect in section, go to form the column of Goll. 5. Another portion of the fibres arising from the cells of Clarke's column leaves the grey substance externally, and dips into the posterior segment of the lateral column, where, bending backwards and upwards, it arches round the lateral pyramidal column, and thus forms the lateral cerebellar columns. 6. Goll's column and the lateral cerebellar columns are composed of similar fibres, which represent a continuation of the posterior root-fibres, effected through the cells of the posterior grey cornua; these fibres run without any further connexion upwards in the spinal cord, and their number therefore progressively increases. 7. Burdach's column, as well as the posterior segment of the lateral column, are chiefly formed of the immediate prolongation of the fibres of the posterior roots, yet these fibres enter into the posterior horns at variable distances above their point of entry. The increase in size of these columns is effected also by the fibres proceeding from Clarke's column and passing through them to Goll's column on the one hand and to the cerebellar columns on the other, and Takács thinks that with these may be associated the fibres which connect the different parts of the column with each other. From these anatomical and histological facts he draws the conclusion that the column of Goll and the cerebellar columns are the continuation of the posterior root-fibres after these have been interrupted by the ganglion-cells of the grey cornua. They constitute the most direct paths for the conduction of sensory impressions. The cuneate fasciculus of Burdach and the posterior part of the lateral column are chiefly transference-points, and are only mediately paths for sensory conduction. It thus becomes intelligible why in the primary stage of tabes and in the lower parts of the cord the fasciculi of Burdach are affected, whilst in the later stages and in the upper part of the cord the columns of Goll are affected. His pathological investigations show that the affection of the fibres of the posterior white columns in tabes stands in direct relation to the disease of the posterior grey cornua, and in these again essentially in relation to its changes in the cells of Clarke's column. The disease of the posterior segment of the lateral column and of the cerebellar columns is relatively less than that of the posterior white columns. He distinguishes lastly two forms of tabes.

EARLY CLOSING.

ACCORDING to the report which has just been issued by the Early Closing Association, the voluntary reduction of shop hours by various employers has been found to exercise a most beneficial effect on the character and abilities of shop assistants. Such an observation is in no way remarkable. It is impossible that work done over time can be of the best quality, or that its ultimate injurious effects can long be postponed. Trade also must suffer somewhat by the failure of energy in those who carry it on; and whatever may be said for securing custom by keeping late hours, we doubt very much whether, if a shorter working day were once inaugurated, its manifest advantages, alike for shopmen and the public, would not secure for it a wide and increasing popularity. Such an introduction has been effected by the Shop Hours Act of 1886. It is hoped that this valuable Act may be administered without any regular system of inspection. In that hope we certainly share, though not without some misgiving. In the circumstances, it is, at all events, satisfactory to learn that the majority of shopkeepers are in favour of the change which the Act is intended to bring about. They appreciate this measure in itself, but are unwilling to assume an individual responsibility in connexion with it unless assisted by a greater consensus of opinion on the subject among themselves than exists at present, and they look for more definite assurances of public support. We would recommend them not to depend quite so much upon prevailing habit. Popular custom in such matters is greatly guided by the methods of trade, and if these be determinately altered as provided by the Act we have little doubt that custom will follow suit Certainly an effort in this direction would now be well timed.

THE GORDON BOYS' HOME.

DIFFICULT as it may seem, the reclamation of the waste land of human nature by intelligent and moral culture has alway proved a success in careful hands. The history of the Gordon Boys' Home, we are pleased to note, affords no exception to this rule. Since its institution fifteen months ago, the affairs of the Home and its occupants have made material progress. The number of boys has increased from nine to eighty-seven; health has decidedly benefited by the influence of fresh air and wholesome food; schoolwork has been methodised and carried out in an efficient manner; while conduct, fair at first, has markedly improved, in spite of considerable difficulties, and without the exercise of any undue severity. The administration is conducted on the military system, and one former pupil has already taken service as a soldier. As is now generally known, however, the Home is not designed to act merely as a feeder for the army or navy; any of the ordinary trades are open to the boys, though it can hardly be doubted that the mode of their training will incline many to pursue a military life. We

Digitized by Google

note with satisfaction that some provision is made in the school arrangements for technical education. Smiths' and carpenters' work, tailoring, shoemaking, and telegraph work are taught with more or less success, and it is significant of the proficiency attained that all the boys' clothes, with the exception of caps and socks, are now made in the establishment. It need hardly be stated that out-door recreations are not forgotten, while two rooms have been fitted up within the Home for amusement during bad weather. There is a library of general literature, and music is represented by a pianette. Friends of the institution have been commendably forward with subscriptions and with gifts, and these we sincerely hope will suffer no decrease in the future. At the same time, it is at least doubtful if, in consideration of the antecedents, age, and undecided future career of most of the boys, such a present as a barrel of beer is a wise selection. It would be well, perhaps, if some rule were made excluding the use of stimulants from the Home except under medical restrictions. So far the memorial project has evidently succeeded. With due care it should yet attain its brightest expectations, and become, in a much greater degree than at present, a trainer in strong, intelligent, and moral manliness.

IS IODOFORM ANTISEPTIC?

THE widespread employment of iodoform as an antiseptic dressing may receive a check should the conclusions arrived at by MM. Heyn and Rovsing of Copenhagen be confirmed. These observers have (*Fortschritte der Medicin*, 1887, No. 2) been making experiments with iodoform to test its value as an antiseptic, which they point out is so generally accepted that the surgeon does not hesitate to employ a non-sterilised spatula or to insufflate ordinary air with the powder, procedures which he would shrink from employing were it not for the belief that the iodoform can destroy the germs adhering to the one or suspended in the other. Yet as iodoform is rarely used to the exclusion of other antiseptics (as carbolic acid or mercuric chloride), there is never much opportunity, clinically, of testing its germicidal properties. Mikulicz, in 1881, tested the action of iodoform upon putrefaction, but with no definite result; and Rummo's experiments in 1883 were complicated by his use of oil of turpentine as a solvent for the iodoform. Meyer found in one case of abscess that iodoform had no effect in reducing the virulence of the pus, and in another that it had a slight action. The results of the research pursued by MM. Heyn and Rovsing surprised themselves. Acting on the theory that it is through liberation of free iodine that iodoform enjoys its germicidal reputation, they prepared solutions of iodoform in olive oil and in serum, and, having sterilised them, mixed them with culture media, and studied the effect of cultures of various bacterial organisms in these mixtures, as well as under iodoform powder alone. They also experimented on rabbits by mixing inoculation fluids with iodoform. The details of the experiments need not be reproduced here; suffice it to say that in no case did the presence of the substance interfere with the development of micro-organisms. So that they conclude that as an antiseptic its employment in surgery is valueless. But, more than this, its use is dangerous, for, as two of their experiments proved, iodoform itself may contain pathogenic micro-organisms; and even if all care be taken to purify it, yet it may become the medium of the conveyance of pathogenic germs introduced into it through the spray or spatula. We trust that these experiments, which have received such prominence, will be repeated, for, if confirmed, we can imagine that the use of iodoform (apart from any other antiseptic) would in certain circumstances be serious. It would be deplorable if in any such case the material upon which the surgeon relies to protect his patient from bacterial invasion should prove to be the means whereby such invasion occurred. The writers of the article themselves advise that before using iodoform (which is valuable as a dressing on other grounds than as an antiseptic only), it should be disinfected in sublimate solution.

THE POWERS OF THE METROPOLITAN BOARD OF WORKS.

THE position occupied by the Metropolitan Board of Works has long been one of a very peculiar nature, and the services rendered to the population of London and its environs by that body have been also peculiar. As a matter of history it will hereafter probably be shown that the Metropolitan Board of Works has bridged over—so to say—the gulf between an obsolete (because exhausted) system of local government and the more perfect organisation by which it is to be replaced. Just now the Board is anxious for more power. It wants to take the public buildings of the metropolis under its protection, not only as regards their construction, but as regards their management. It would like to manage everything, and do all the licensing as well. These things could scarcely be done less efficiently than at present, so that we are not prepared to check the omnivorous propensity of the Board. By all means let Sir James M'Garel Hogg and his colleagues take over the entire business, and if there be something so soporific in the police officialism of the metropolis that a Chief Commissioner must needs forget to protect the streets in the neighbourhood of a mass meeting of roughs, as Sir Edmund Henderson forgot Pall Mall and Piccadilly, and as Sir Charles Warren has since, whilst otherwise taking admirable and most necessary precautions, forgotten Goswell-road, it may become desirable that the Board should add to its other cares that of the police control of the metropolis, vice the authorities of Scotland-yard, resigned.

A NEW METHOD OF SEWER VENTILATION.

A NEW proposal has just been brought forward for the ventilation of sewers. It has the merit of originality and ingenuity. Mr. R. S. Ash has patented a system of ventilation by the force of concussions resulting from explosion automatically produced. In the man-hole of a sewer, or in the ventilating-shaft of a coal-mine, &c., he places a small cylinder where coal gas accumulates till it reaches a little hole, and there comes in contact with a jet burning outside. An explosion results and the lid of the cylinder is blown off, but counter-weights make it fall back in its place, so that all is ready again for the next explosion. Of course the air is blown out of the man-hole, and a vacuum created and filled by the air rushing up from the sewer, but this displacement is not the principal merit of the process. A ventilating fan or revolving wheel and a furnace will equally produce a current of air; but such current generally travels down the central and main sewers, and leaves almost untouched the accumulations of foul gas in the branch sewers, in the angles and in other inaccessible places. A shock, however, does not travel in a straight line, but spreads out in a circle. A stone thrown into a pool of water affords the readiest illustration of this fact. Let the edges of the pond be jagged and angular, the ripple will travel up every little crevice or opening in the banks. A current, on the other hand, even the current of a rapid stream, leaves quiet nooks made by the recesses of the embankment, where a boat may be safely moored without risk of its being borne away. Thus an explosion in a sewer will with more certainty move the air in the branch sewers and out-of-the-way passages than will a strong current down the main channel. Also it should be noted that it is precisely these branch pipes and

Digitized by Google

sewers which are nearest to the inside of the dwelling, and therefore most urgently need ventilation. Consequently, if ventilation by concussion or explosion can be made to act without involving too great an inconvenience and expense, it is likely to prove as valuable a progress in practice as it is an advance in theory.

GASTRIC AFFECTIONS AMONGST SWEDISH PEASANTS.

DR. WIESENER mentions in the *Medicinisk Revue* that in part of Sweden gastric affections are very common. These he comprises under the general term "cardialgia." They include, however, chronic gastritis, dyspepsia, ulcer of the stomach, dilatation of the stomach, nervous cardialgia, and carcinoma. The first two of these are less common than the others. The main causes are to be found in overwork and injudicious diet—the usual lot of the poorer inhabitants. It is not that their food is actually insufficient, but it contains too little nitrogenous matter and too much carbo-hydrate, vegetable albumen taking the place of animal albumen, and quantity being substituted for quality, which impedes the mechanical and chemical processes of the stomach. Again, such meat and fish as the peasants do eat is usually salt, and their milk is sour; indeed, the fish is often in a partly decomposed condition, containing ptomaines. The porridge too, which in many places forms the staple of the peasant's dietary, is frequently insufficiently cooked, so that the starch is unchanged in the alimentary canal. These diseases are seldom met with until after the age at which young people take part in heavy out-door work. As to treatment, both of a prophylactic and curative character, Dr. Wiesener recommends more rest, attention to cleanliness (which is sadly wanting in the culinary operations), more fresh meat and vegetables, and an improved method of preserving milk &c. As to drugs, alkalies, hydrochloric acid, bismuth, magnesia, and carbolic acid may be found useful according to circumstances.

SUICIDES OF CHILDREN.

WE have no means of knowing whether suicides among children are proportionally more numerous within the last few years than they were previously. Attention has been specially directed to these most lamentable occurrences recently, and this may account for the fact that an increased number of cases are from time to time under notice. There is something especially distressing in the fact that consciousness may be, and often is, so painfully influenced by circumstances in the early stages of life that death is sought as a relief from misery. We do not think that a man or woman must needs be insane to seek death as an escape from trouble. It seems to us that well within the limits of sanity a perverse, or morally cowardly, or very much worried consciousness may reason out the proposition that life is not worth living, and conclude to die. Precisely the same processes which go on in the mind of an adult may be in operation in the mind of a child. There is, in short, no reason why the young should not commit suicide as well as the old, if only hope—which in a very practical way may be said to be an essential of life—is crushed out of existence. The mind in which hope dies may court death, and yet be in no sense *morbid*. It is difficult, but it is possible, to slay hope in the life of a child, and when this is accomplished it is not unreasonable to suppose that despair may end in self-slaughter. The intense haste of life and enterprise is doubtless one of the causes of suicide, and there can be no question that our system of forced education, and the premature imposition of hideous brain-tasks on the young, press heavily on the consciousness. We venture to think this subject of suicides among children is one which ought to be taken into very serious consideration by those who are responsible for the operation of laws which may ultimately render the population more erudite, but which will not, unless greatly modified, make them happier, or in a social sense more prosperous, than heretofore.

SUDDEN DEATH IN PLEURISY.

SOME years ago the occurrence of a series of cases where death suddenly took place during or after the operation of paracentesis thoracis led to much discussion, especially in the Paris Société Médicale des Hôpitaux, without, in many instances, clearing up the cause of the fatal event. Post-mortem examination often failed to reveal lesions, although the fatal attack was in most cases ushered in by convulsions. Of late we have heard less of such accidents; but the subject of sudden death in pleurisy is one which deserves study. Dr. Weill of Lyons contributes to the current number of the *Revue de Médecine* an essay concerning it, which hardly includes the class above alluded to where the seizure supervenes upon operative interference. He speaks rather of cases of pleural effusion that are unrelieved by art, and arrives at the following conclusions: That sudden death in pleurisy is allied to certain lesions—such as cardiac or pulmonary thrombosis or embolism; œdema of the opposite lung, and changes in the myocardium. Such derangements as grave syncope, mechanical impediment to the circulation from displacement of the heart and torsion of the great vessels, and hypothetical lesions, as multiple cerebral embolism, may be provisionally accepted, but require further investigation before being accepted as adequate explanations of the event. Sudden death may occur in various forms of pleurisy—in right pleurisies more often than in left, in acute or in chronic cases, and in cases of progressing, stationary, or absorbing effusion. The effusion is generally serous. The cases may or may not be accompanied by special symptoms, such as attacks of dyspnœa, syncope, and irregularity of pulse; but often death will occur quite unexpectedly without any premonition, and following upon some movement or effort on the patient's part. Paracentesis is the only prophylactic measure, and would be indicated by the onset of threatening symptoms, or evidence of heightened intra-pleural pressure.

PETITION OF THE BELGIAN MEDICAL FEDERATION.

THE Belgian Medical Federation, after a good deal of discussion, has agreed upon a petition, which it has addressed to the members of the legislative chambers on the subject of medical legislation. Discussing the question of examining bodies, the Federation expresses a distinct preference for the plan of a central jury, believing that it secures a fairer but more stringent and satisfactory examination than that of juries composed exclusively or mainly of the professors under whom the candidate has studied, and whose questions he can probably answer if he has merely a retentive memory. An opinion is also expressed that professors alone should not be allowed to form a jury, but that a certain number of practitioners should be associated with them. A State examination for all would, in the opinion of the Federation, exert an influence of the best kind on the instruction given in the four universities by setting up a noble emulation between them—"each of them labouring, not, as heretofore, to send into practice the greatest possible number of its alumni, with diplomas of questionable value, but to surpass its rivals by obtaining a greater amount of success at the State examinations." Of course, the Federation hopes that all foreign practitioners will, before being allowed to practise in Belgium, be obliged to go before the central jury, and, as the holders of Belgian University degrees will have to be examined, there cannot be any hardship in obliging the holders of foreign

Digitized by Google

degrees to undergo the same test. The Federation wishes dentists to be obliged to take medical diplomas. An important recommendation is contained in the portion of the petition upon "*le stage médical.*" This *stage* is represented by the time of hospital clinical study, but according to the Federation it is much too short. No regulation insisting on a further time for clinical work appearing to be practicable at present, the Federation suggests that in view of the ever-increasing overcrowded state of the profession and the unwisdom of encouraging more young men without private means to enter it, it would be well to desist from offering scholarships to first-year's students and to employ the funds thus set at liberty in giving travelling exhibitions to those who have finished their course for the purpose of enabling them to prolong the *stage médical* with profit to themselves and their future patients. The Federation concludes by suggestions for a special education and diploma for experts in forensic medicine.

ARTIFICIALLY PRODUCED RELAPSE OF ERYSIPELAS.

DR. BORN of Cöthen contributes to the *Allgemeine Medicinische Central-Zeitung* an account of a case of erysipelas in an elderly woman, which was apparently brought on by eating some insufficiently cooked fish, which also disagreed with other people who partook of it. After the erysipelas (which had been extensive and accompanied by a good deal of fever) had disappeared, the patient remained in good health for six days, being only inconvenienced by the presence of a dried film of carbolic oil which had been used to anoint the affected surface. At the end of this time she received permission to wash herself, which she did pretty thoroughly with soap and flannel. The same evening her temperature rose again, and she suffered from rigors, heat, and headache, erysipelas reappearing the next morning, which arrived at its crisis on the tenth day and shortly afterwards disappeared. There seemed to be no doubt as to the connexion between the washing and the relapse. Dr. Born suggests that the infecting micrococci may have been lying dormant in the skin or subcutaneous tissue, the rubbing sending them into the circulation; or else that infective matter may have been external, and reintroduced by minute scratches or abrasions produced by the scrubbing. The public are, he says, known to have a great fear of washing in erysipelas, and this case would seem to show that there may be some ground for it. Dr. Born goes on to remark that medical men are told of individuals who have repeated and regular attacks of erysipelas more frequently than they see such cases for themselves, and he suggests that here it is more probable that dormant centres of infection exist in the body, which at times are brought into the circulation, and so rendered capable of causing an attack of the disease, than that the persons in whom these repeated attacks occur are again and again infected from outside.

AN EXPERIMENT ON HUMAN LIVES.

"IT behoves such populations as Ripon and York, which derive their drinking-water from a river seriously contaminated by agencies beyond their own control, to be aware that they are having an experiment performed upon their lives, an experiment contrary to the provisions of the English law." Such are the sufficiently striking terms in which Dr. Buchanan refers in the fifteenth Annual Report of the Local Government Board, which has just appeared, to the pollution by sewage of the river Ure. Strong as this language is, it is undeniably justified by the facts of the case. Briefly they are these: The Ure rises in the hilly country which lies upon the north-western border of the North Riding; it runs through Wensleydale, passing in its route through numerous villages and hamlets, and the little town of Masham. Winding on in a southerly direction, it eventually joins the Ouse, about fourteen miles above the city of York. All along its course it is used alternately as a sewer and a source of water-supply. At Masham, which lies about twenty-two miles from the source of the river, it receives the drainage of a town of 1000 inhabitants; and at Ripon, some fifteen miles further down, it supplies drinking-water to a population of nearly 8000, and receives drainage in exchange from the same town. Pursuing its course, it passes through several other villages which contribute still more sewage to the stream; and after joining the Ouse at Boroughbridge, a place situated some eight miles below Ripon, it flows on through the city of York. Mr. Sweeting, who made the inspection of the river, sums up the facts relating to York as follows: "The Ouse has, by the time it gets to York, received not only a considerable amount of impurity that has been brought into it by the Ure above Ripon and by the Swale, but also the drainage of the city of Ripon, of five small villages, and of Boroughbridge..... The sum total of contamination contributed by the Ure to the Ouse is therefore great." It is reassuring to learn that analysis seems to show that the Ouse water is not ordinarily affected to any serious extent by this abundant pollution, but it is certainly no unwarrantable use of language to describe it as an experiment upon human life.

THE ASYLUMS BOARD AND THEIR MEDICAL SUPERINTENDENTS.

A NEW discovery has been made of the extravagance and mismanagement of the Metropolitan Asylums Board. The City of London Board of Guardians have found the "painful fact" that at present there are no fewer than three medical superintendents in the employ of the Metropolitan Asylums Board for whom there is really no occupation whatever, and whose salaries range from £400 to £500 each, with rations and other privileges. The guardians can have no desire that medical knowledge shall increase, for they fail to see that the ratepayers would be distinctly benefited by the employment of medical men in investigations which would add to our means of treating disease successfully. It has been too much the custom of the managers at the close of every epidemic to dismiss a staff, some members of whom could render important service in the direction we have indicated; in times of epidemic pressure there is but little opportunity for work of this nature, but in the intervals it should be seriously undertaken, and it is a standing reproach that so little attempt has been made to turn to good account the material for study which is at the disposal of the medical officers of the managers.

ANTI-PYRETIC ACTION OF NITROGENISED AIR.

DR. FRANCISCO VALENZUELA of Madrid has made some observations (published in *El Siglo Médico*, Jan. 30th, 1887) on the effect of inhalations of nitrogen, or rather of air containing an abnormally large proportion of nitrogen, upon febrile diseases. He compared its action in reducing temperature with that of cold applications, quinine, antipyrin, digitalis, and arsenic, and concludes that the inhalation of nitrogen is the only method of treatment the cessation of which for a day is not followed by a rise of temperature to its former height. It has also, he believes, a beneficial effect on the diseased process itself. The plan adopted was to administer the nitrogen in two daily sittings of from half an hour to an hour in duration, beginning with air containing 17·76 per cent. of oxygen, and gradually decreasing this proportion till at the close of the sitting it was reduced to 12 per cent. Some few details are given of a

Digitized by Google

phthisical case in which it was tried. At first some dyspnœa was produced, but the evening temperature at once sank to normal, in addition to which the cough decreased, the blood almost entirely disappeared from the sputum, the sweats became less frequent, and the appetite improved. This patient had been previously treated by quinine, with but little good result. No other cases are reported, though several other patients were treated in this manner, most of whom are stated to have been benefited by it.

PHYSICIAN AND PHILANTHROPIST.

THE profession in Italy has been gratified by the royal recognition of a well-known "companion in arms." King Humbert, *proprio motu*, has made Commendatore of the Order of the Crown of Italy Dr. G. B. Trombini of Milan, in consideration of his judiciously applied and munificently sustained philanthropy. Charity unless wisely bestowed has long appeared to Dr. Trombini as worse than useless, and accordingly he makes himself personally cognisant of every case that appeals to him for help. But such help should be something more than mere almsgiving, and as he has his *protégés* under his eye, so he sees to their being usefully employed with a view to their self-rehabilitation. He has thus become the patron of an establishment at Melegnano, where 800 recipients of his bounty are kept usefully at work—an institution from which society is periodically reinforced by skilled and able hands who would otherwise have been lost to it. Furthermore, by the rule of *principiis obsta*, he has just established at Melegnano an infant asylum on a magnificent scale, where every physical and mental want of the waifs and strays of fortune will be judiciously met by a well-appointed organisation. This institution, suggested to Dr. Trombini in an hour of anguish after the loss of two sons on whom he doted, has already cost him 300,000 francs, and will form the most fitting and enduring monument of a citizen whom adversity has not soured, and who values wealth only as a means of raising and reinforcing his fellow-man.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

ON the 7th inst. there died at Berlin, at the early age of forty-nine, after a fortnight's illness with brain fever, brought on by overwork, Professor Carl Schröder, one of the best-known gynæcologists in Europe. His Hospital for Women at Berlin, with which his name will always remain associated, attracted crowds of students and patients from all parts of the world. Professor Schröder was a voluminous writer, some of his works—notably, his Manual of Midwifery, including the Pathology of Pregnancy and the Puerperal State"—having been translated into English. The following deaths are also announced:—M. le Dr. Snyers, one of the best known and most highly respected practitioners of Liège. Señor Dr. Don Francisco J. de Castroy Perez, Professor of Therapeutics in the University of Madrid.

THE TREATMENT OF FRACTURED PATELLA.

IN the report of the Sabbatsberg Hospital, Stockholm, recently issued, Dr. Söderberg has collected a number of cases of fracture of the olecranon and patella, in which a cutting operation has been performed—that is to say, where an incision has been made and the fractured surfaces (after being pared if necessary) sutured. A large proportion of the cases are from English sources, but there are some reported by American and continental and a few by Swedish surgeons. Altogether Dr. Söderberg has analysed 81 cases. A good result was obtained in 51; in 9 there was ankylosis, in 5 suppuration with impaired mobility, in 9 impaired mobility without suppuration, and in 3 fibrous union, while death occurred in 3. To separate the recent from the long-standing cases: Of the 43 recent cases a good result was obtained in 37, ankylosis occurring in 1, suppuration in 1, partial mobility in 3, and fibrous union in 1. The 38 cases of long-standing showed, as might be expected, a much worse series of results, there being only 14 which could be classed as good, while 3 were fatal and 8 ended in ankylosis. The author speaks with considerable reserve about the operation. In recent cases it is naturally less dangerous, but here it is, as a rule, quite unnecessary. In such cases of long-standing as present facilities for the operation, the statistics of the future may be expected to show better results than those of the past. Where, however, there is adhesion between the posterior surfaces of the fragments and the posterior walls of the capsule, as there was in a case occurring in the Sabbatsberg Hospital, of which the details are given, little or no good effect is usually produced by the operation. Dr. Söderberg seems to have missed a good many cases published by English and French surgeons—notably some forty collected by a French surgeon, details of which appeared in THE LANCET a few years ago. Altogether the cases published up to the present time must amount to more than 120, and there are besides several successful cases known to us which have not as yet appeared in print. It may be remarked, too, that in the cases published by Mr. G. R. Turner, and referred to by Dr. Söderberg, fibrous union was obtained rather more often than is stated by the latter writer.

THE COUNTESS OF DUFFERIN'S FUND.

WE are glad to learn that the Countess of Dufferin's Fund is being well supported and likely to prove a success. The statistics of India, though far from perfect, afford evidence of a very high rate of mortality among children under five years of age, and in the female population at the child-bearing age. It is to these two classes especially that the fund will prove beneficial by providing skilled medical assistance through the medium of qualified female doctors. The rules of caste and the customs of the country deprive them of the aid of the male members of the profession. There can be no doubt that by the introduction of educated female medical practitioners a great saving of life and reduction of suffering will be effected, especially in these two groups.

THE SIGNIFICANCE OF URIC ACID DEPOSITS IN URINE.

DR. JOHANNES MYGGE, while chief of Professor Trier's clinic in Copenhagen, having repeatedly remarked abundant and persistent deposits of uric acid coinciding or alternating with albuminuria, carried out a series of examinations on the urine of the 272 male patients under his supervision. Of 3287 urines examined, 2786 from 127 patients were entirely free from uric acid deposits, while they were found in 501 specimens from 105 patients, but only in any considerable quantity in 262 specimens from 59 patients. In 43 of these last patients the deposits were of a transitory character—that is, they were only observed once or twice; while in the remaining 16 they were found to persist for a week or more. Deposits both of a transient and of a permanent character were found, especially in rheumatic affections, whether of an acute or chronic form. Transient deposits were found also in pneumonia in 11 cases out of 25. In 27 out of the 59 patients in which uric acid deposits were observed albuminuria was also present in appreciable quantity, and in many of the rest there was a doubtful trace noted. Dr. Mygge's observations confirm Dr. Dickinson's statement that deposits of uric acid of a transitory character frequently coincide with the suppression of acute albuminuria. In the majority of cases where the deposit was

Digitized by Google

examined microscopically, casts or tubal epithelium cells were found, indicating that some connexion probably exists between uric acid deposits and functional renal disorder. In some instances, it may be supposed that a peculiar condition of urine, especially its supersaturation by uric acid or an increase in its acidity, has irritated the epithelium of the tubes, and has thus set up a renal lesion. In others, the latter condition doubtless precedes the precipitation of uric acid, and here Esbach's theory of the precipitation of uric acid being due to the existence of morphological elements in the urine may afford an explanation.

THE MOXON MEMORIAL.

A MEETING of the sub-committee appointed to determine the form of memorial best adapted to perpetuate the memory of the late Dr. Moxon was held at the Royal College of Physicians on Feb. 8th, and was very fully attended. Sir Joseph Lister proposed, and Sir Andrew Clark seconded, the following resolution, which was carried unanimously:—"That the fund raised by subscription be devoted to the foundation of a scholarship or medal, to be awarded by the Royal College of Physicians, and to the erection of a memorial of him at Guy's Hospital."

ALLEGED TOXIC EFFECTS OF COCAINE IN THE BLADDER.

IN the surgical section of the Madrid Medico-Chirurgical Academy, Dr. Call read a paper on the Effect of Cocaine on the Bladder. He found that fifty centigrammes of a 1 per cent. solution of the hydrochlorate injected into the bladder produce convulsive movements, upon which Dr. Osio remarked that this toxic action might very probably be due to the development of microbes in the solution.

"THE GRAPHIC AND GUY'S HOSPITAL."

THE issue of the *Graphic* for the 5th inst. contains a well-executed illustration of the Accident Ward of Guy's Hospital on Visiting Day, when the patients receive the members of their families from whom misfortune has separated them. The picture may, as we hope it will, enable those who are not personally acquainted with the inner life of the institution to understand a part at least of its usefulness, and stimulate the response to the appeal which has recently been issued on behalf of its funds.

THE HUNTERIAN ORATION.

THE President of the Royal College of Surgeons, Mr. W. Scovell Savory, F.R.S., will deliver the Hunterian Oration in the theatre of the College, on Monday, the 14th inst., at 3 P.M. precisely.

MEDICAL APPOINTMENTS IN INDIA.

DR. VANDYKE CARTER, we learn, has been appointed to be Principal of the Grant Medical College at Bombay, and Physician to the Jamsetjee Hospital there, in the room of Dr. Cook, F.R.C.P., retired. Mr. D. N. Parakh, M.R.C.S., L.R.C.P., has been appointed to be surgeon to the Goculdas Hospital in Bombay, in the room of Dr. Carter. Mr. J. B. Eaton, M.B., will, we believe, succeed Mr. Parakh as assistant-surgeon to the Sassoon Hospital in Poonah.

THE INTERNATIONAL MEDICAL CONGRESS.

WE understand that the owner of the steam yacht *Ceylon* is anxious to place his vessel at the disposal of members of the medical profession and their families who intend to visit America during the Congress. The cost per head (inclusive of everything) would be, we believe, £50, but at least sixty passengers would be required.

FOREIGN UNIVERSITY INTELLIGENCE.

Basle.—Dr. Bischoff, Professor of Midwifery and Gynæcology, has been obliged by ill-health to resign his post.

Brussels.—M. le Dr. Marique has been nominated chief of the post-mortem examination department. Some new courses have been recently opened on advanced toxicological chemistry, elementary biological chemistry, chemical and micrographical study of alimentary substances, and the detection of their alterations and adulterations.

Greifswald.—Dr. Grawitz, Extraordinary Professor of General Pathology and Pathological Anatomy has been appointed Ordinary Professor.

Leipzig.—Professors Olshausen of Halle, Zweifel of Erlangen, and Fritsch of Breslau, having been selected for the vacant chair of Midwifery, the offer was made to Professor Olshausen, whose name stood first on the list. He has, however, signified his intention of remaining at Halle. Dr. R. Altmann, Prosector of the Anatomical Institute, has been appointed Extraordinary Professor.

Leyden.—Dr. H. Treub has been nominated to the Professorship of Midwifery and Gynæcology, vacant by the death of Dr. S. Thomas.

Lyons.—For the chair of Experimental and Comparative Medicine, vacant by the death of M. Chauveau, M. Arloing has been selected by the Faculty of Medicine, the second name mentioned being that of M. Rodet.

Madrid.—The Minister of Education has just published a regulation applying to all Spanish faculties of medicine and pharmacy, obliging all students on their first matriculation to show that they have passed successfully through a year's course of instruction in French, but permitting the certificate of a similar amount of knowledge of German to be deferred till the end of the first year. This delay, however, will only be permitted for a short time, after which the original regulation insisting on both French and German certificates on matriculation will be enforced.

WE learn with great regret that Professor de Chaumont of Netley is seriously ill. Dr. de Chaumont is a singularly able and accomplished man, whose scientific work has secured him a deservedly great reputation, and we heartily trust to be able to announce next week his favourable progress towards recovery.

A COURSE of post-graduate lectures on Bright's Disease is now being delivered by Dr. Robert Saundby in the library of the Birmingham Medical Institute. The lectures commenced on the 9th inst., and will be continued on the next three Wednesdays, commencing each day at 4 P.M.

IN accordance with the resolution of the Epidemiological Society, the Council are about to consider the various Acts of Parliament having relation to sanitary administration, and propose in the first instance to consider the Public Health Act, 1875.

THE citizens of Nairn are about to perpetuate by a bronze statue the memory of the late Dr. John Grigor, in gratitude for his services as a medical practitioner, and for his munificence as a public benefactor.

AN outbreak of diphtheria, which has assumed formidable proportions, is reported as having occurred at Whitstable-on-Sea.

MRS. BANCROFT will give a recital on the 18th and 19th inst., at the Novelty Theatre, for the benefit of the Belgrave Hospital for Children.

THE HIGH ALTITUDE TREATMENT OF PHTHISIS.

(FROM A SPECIAL CORRESPONDENT.)

No. II.

Davos; the Indications and Contra-indications for and against the High Altitude Treatment of Phthisis; the recent Results of Treatment at Davos; Precautions regarding the Journey.

THE high altitude treatment is still sufficiently novel to leave considerable room for doubt regarding the classes of patients which can be confidently recommended to have recourse to the Alpine health-resorts. Nevertheless, every year now adds abundant data towards the formation of a correct conclusion on this important topic, and it is much to be desired that the profession should be made acquainted with the rich results of clinical experience now being gathered at Davos and elsewhere.

In approaching this question one preliminary error must be pointed out. Some writers fail entirely to distinguish between cases which do badly at Davos and those which do badly anywhere and everywhere. It adds nothing to our knowledge to inform us that cases of phthisis complicated with albuminuria do badly at Davos, for we know that such cases are beyond the reach of all climatic treatment. As little does it help towards a clear understanding of the special function of the Alpine sanatoria to say that cases of laryngeal phthisis fare badly there, as we may pertinently ask, Where do they fare otherwise than badly? On the other hand, it is of little value to inform us that the cases for Davos are those of chronic phthisis without hereditary predisposition, where there is immunity from visceral complications and the retention of digestive and circulatory vigour, because such cases as a rule respond fairly well to any climate where the meteorological conditions are more favourable to health than those amidst which the disease was contracted. We must come to closer quarters with the problem and avoid those generalities which are part of the general prognosis of phthisis. What we want to determine is this—In what classes of case may Davos be expected to prove decidedly more efficacious than Cannes, Madeira, Algiers, or Egypt? Secondly, What types of phthisis are likely to be injuriously affected by the peculiar features of the climate of high altitudes? Let us look first at the latter question, as admitting of a readier and more definite answer.

All authorities are agreed that patients with weak circulation should on no account be sent to the mountains. Circulatory weakness is the first and most conclusive contra-indication against the high altitude, and the reasons for this rule are too obvious to need amplification. Organic heart disease, such as valvulitis, is not an absolute contra-indication. The main point is the integrity of the cardiac muscle and the degree of efficiency with which the circulation is maintained. A patient with valvular disease, but in whom compensation is well maintained, may be freely recommended to try Davos; but, on the other hand, a case in which there is no actual cardiac disease, but marked functional weakness of the circulatory apparatus, should be prohibited from resorting to the mountains.

The next most important contra-indication is the presence of senile change. No doubt this point should be viewed in close conjunction with the former one, since arterial degeneration is probably the main reason why elderly patients fare ill among the Alps.

Gout and rheumatism are contra-indications which need only be mentioned in order that their importance may be appreciated. Organic nerve disease and hysteria are also prohibitive to the adoption of the mountain treatment, no doubt because of the highly stimulating properties of the climate of high altitudes.

Cases of phthisis in which dyspepsia is a prominent symptom cannot be sent to Davos without some misgivings, although the facts do not warrant the presence of dyspepsia being regarded as an absolute contra-indication. Almost every case of phthisis is sooner or later complicated with digestive troubles, but it is only where these are very obstinate that the high altitude treatment is definitely contra-indicated. It has been remarked that some patients with whom diarrhœa has been a troublesome symptom obtain speedy relief from this annoyance at Davos. It need hardly be said that no relief may be expected if there is any reason to suspect that the diarrhœa depends upon intestinal ulceration.

The last contra-indication to which we will draw attention is that peculiar condition known to German authorities as the *eretische constitution*, or the erethic diathesis. It is impossible to define exactly what is meant by this term, but every physician has a fairly definite conception of what is included under it. Probably the main feature in a constitution of this type is some species of nervous and circulatory instability. But whatever be the erethic constitution—and each observer must form his own conception of it—its presence is an absolute contra-indication to the adoption of the high altitude treatment.

Let us now look at the converse side of the question, and inquire to what classes of the malady the mountain treatment is specially applicable. In the first place, there can no longer be much doubt that in a considerable proportion of cases of early phthisis, where there is freedom from severe pyrexia, marked emaciation, and renal complication, the high altitude treatment is not merely palliative, but actually curative. The Davos doctors claim from 10 to 15 per cent. of cures, and anyone who visits the valley will find numerous individuals who arrived there with fully-developed phthisis, but who are now either restored to complete vigour, or, at least, are succeeding in keeping the destroyer indefinitely at bay. Some of these convalescents return to the lowlands and resume their avocations with safety, but many others find themselves compelled to settle permanently at Davos. It is a point worthy of the most careful study what proportion of the alleged recoveries are absolute cures, and what proportion are contingent upon the convalescent remaining in the climatic and hygienic conditions in which the cure was effected. The latter will undoubtedly be found to constitute a considerable percentage.

Cases of phthisis which exhibit a "torpid reaction" are those most suitable for the mountains. In other words, patients should not be sent to Davos unless they are capable of supporting and responding to the high stimulating climatic conditions which there prevail. This is a very obvious consideration, but, next to indications afforded by the circulation, it is the most important clue to the proper selection of cases.

Dr. Ruedi has remarked that cases of hæmorrhagic phthisis, where the hæmorrhages are profuse and the physical signs slight, are very favourable for treatment at Davos.

Apart from phthisis, there are many morbid conditions which respond readily to the high altitude treatment. Old pleurisies and unresolved pneumonias often undergo marvellously rapid improvement—a fact which is easily explicable when we remember that the aerial rarefaction promotes lung expansion, and the general climatic conditions stimulate nutrition and tissue changes.

Asthma often does well at Davos, but every practitioner is aware that no precise rules can be laid down regarding this erratic malady.

Cases of nervous exhaustion from excessive brain work often benefit decidedly by a resort to the high altitudes. In these patients the mountain air often acts as an excellent hypnotic, and with the return of sleep the other symptoms are rapidly relieved. It is, however, a *sine qua non* in such cases that the patient shall give up all intellectual effort and take absolute rest.

As a general rule, a certain amount of constitutional vigour is necessary to enable a patient to withstand the cold of the high altitude climate and to respond to its stimulating action. On this subject, however, any hard-and-fast rule would be fallacious, as undoubtedly some patients who arrive in a state of marked prostration subsequently rally and benefit by a residence at Davos. Nevertheless, there can be no more pernicious error than to suppose that the air of the higher Alps is any specific for advanced phthisis.

Do hopeless cases of phthisis pass the remnant of their days more easily at Davos than elsewhere? I can only answer—*cela dépend*. There is no rule. Some patients, who have tried all resorts, deliberately go to Davos in order to die as comfortably as possible, but probably a still larger number of moribund cases experience some relief on removal to the softer air of Mentone or Madeira. It seems natural that the dying should seek soothing and sedative climatic conditions rather than those that are pre-eminently stimulant.

An important question arises, whether invalids should go

Digitized by Google

direct to Davos or break the journey at some intermediate stations. Probably, if the circulation is vigorous and the nervous system fairly sound, a journey direct is the less of two evils; but if there is any reason to dread cardiac failure or severe nervous disturbance, the need for a halt at some intermediate points is imperative. The best places at which to break the journey are Ragatz and Klosters. Coire may be selected if the Landwasser route is chosen. The invalid should not stop either at Landquart or Küblis. Some German authorities urge that, whatever practice be adopted on the upward journey, there should be no exception to the rule of making the descent to the plains by several stages.

Patients begin to arrive at Davos early in October, and by the end of November the winter colony is assembled. It is one of the moot points when the patient should arrive. It used to be taught that it was a mistake to arrive before the valley was fully invested with its winter robe of snow—a rule which would delay arrival until the third or fourth week of November or later. The Davos doctors now teach that the earlier the patient arrives the better—September being a good month,—and that the more serious the case the greater is the need for a timely arrival. This seems reasonable, and English practitioners should note this point carefully, inasmuch as the neglect of it may lead to the disappointment of even well-founded hopes.

REPLANTATION, TRANSPLANTATION, AND IMPLANTATION OF TEETH.

REPLANTATION consists in the return of a tooth to the same cavity from which it has been extracted. Transplantation is the extraction of a tooth of one person and transferring it to the socket left in the mouth of another by the extraction of a tooth. Implantation is the ingrafting of a natural tooth into an artificial socket.

Replantation is performed when teeth have been knocked out, extracted accidentally or in error, sometimes to rectify malposition, and occasionally for disease. In the first three cases the tooth is simply cleansed in some antiseptic solution, forced into place, and kept fixed by means of ligatures. These cases do extremely well; even if the tooth has been out of the mouth some hours, union certainly takes place between the periosteum of the tooth and that of the socket; but whether the circulation in the pulp ever becomes re-established is not absolutely known. It has been inferred, because these teeth often lose none of their natural translucency, which is always the case when a pulp is dead; but there is no authenticated proof of this; it is therefore the practice of many to remove the pulp and fill the nerve canals before replacing. When there has been for a long time a chronic alveolar abscess, the offending tooth has been extracted; the diseased portion, which is invariably the apex, being cut off, it is put back into its socket, a hole being left through the fang to allow for drainage. This operation has not been very successful, and is almost entirely abandoned, at any rate in this country.

Transplantation is a very old operation. John Hunter, one hundred years ago, spoke of it as being in his time a habitual practice, and gave a very practical and detailed description of the procedure. When he was about to perform the operation he had half a dozen persons ready, so that if one "scion" tooth, as he called the one to be transplanted, did not fit the socket, another was at hand if required. He believed that the circulation in the pulp was restored, both from the translucency of the pulp and from the results of his oft-quoted experiment of transplanting a tooth into a cock's comb, which, by the way, he says in a foot-note, succeeded but once in a great number of trials. The objections are numerous: first, there is the difficulty in obtaining healthy fresh teeth which will fit the socket, the liability of the transmission of disease, the uncertainty of the result, and the comparatively short time the teeth last, three years being a good average. Notwithstanding, every decade the operation is reintroduced with some modifications in detail, only to fall into desuetude.

Quite recently, Dr. Younger of San Francisco brought before several dental societies, and published a monograph on, a method which he calls implantation. It is applicable to cases where teeth have been extracted and the alveolar crypt filled up with cancellous bone. An artificial socket is made with a trephine or large drills; a dead tooth, no matter how old so long as its periosteum remains intact, rendered aseptic and its pulp canal filled, is then inserted into the socket and ligatured in places. It is maintained that the great difference of this operation is that the tooth is placed in a healthy, not a diseased, socket. In his early attempts he used fresh teeth, which he obtained from other dentists, and which he endeavoured to keep alive by implanting them in cocks' combs, so that one had visions of a farmyard of cocks armed with teeth as well as spurs; but he soon abandoned this, presumably because he failed. He has performed fifty operations since June, 1885, two of which were failures. There is unimpeachable evidence that a large number of these teeth have retained their positions, but the question is how long will they continue to do so. We certainly should not expect this to be any more successful than transplantation with fresh teeth, and those that are not thrown off at once either by absolute failure to unite, or subsequently from alveolar abscess, will in time, as past experience has shown, become absorbed just as ivory pegs are in bone.

COCAINE IN DENTISTRY.

MR. MORTON SMALE, at the last meeting of the Odontological Society, made a communication on the use of Cocaine. He advocated the formation of a subcommittee of investigation to experiment with the drug in order that an authoritative utterance might go forth to the members of the Society and the profession at large as to its value; for at present, with regard to dentistry, the profession and the public are in a state of suspended judgment in relation to it. He said: "I began using cocaine early in 1884, and have used it more or less ever since. In the Westminster Hospital Report for 1885, I thus speak of it: 'In extraction, if the drug is applied to the gums surrounding the tooth (the part having been first dried and protected from saliva, or the cocaine will be washed away) the pain attending the adjustment of the forceps is obviated, but the wrench attending the fracture of the alveolus and rupture of vessels and nerve at the apical foramen is much the same. A small loose stump may be removed painlessly. In cases of fractured teeth, where it is necessary to remove the pulp, cocaine is useful. Applied to the surface of the exposed pulp it will deaden sensibility, and if applied several times at short intervals the nerve extractor can be inserted and the pulp extracted with very little pain. This drug is of distinct value in practice, and should be in every dentist's consulting-room.' The experience of injecting it into the gum tissues has caused me to enlarge very materially my views about it. I have been using 5, 10, 15, 20, and 25 per cent. solutions of hydrochlorate of cocaine; the weaker ones I have discarded in favour of the four stronger ones. Of the cocaine faintness I have seen and heard very little, except in the journals; the only case was in a man who felt faint at the insertion of the needle, and who, when he was vaccinated a year or two before, nearly fainted. I can hardly quote cases in a short casual communication, but I have used it successfully for the following purposes: extractions, torsion, removal of live pulp, inserting hickory wedge between teeth for stopping purposes. These operations, all very painful ones, have been done almost without pain, so much so that they were easily endurable. In cases of removal of pulp, I have, in addition to injection, always applied the drug to the surface of the pulp. A few days since I applied it both by injection and to the cavity in a patient who had some exquisitely sensitive cavities on the buccal surface of some molars and premolars, but the result did not come up to my anticipation. The patient said the pain was lessened, but it was still painful. I was anxious to be able to speak from personal experience, and, as I could not afford to lose a tooth, thought I would try the next most painful operation in dentistry. This, I consider, is the rapid separation of two front teeth. I therefore inserted five minims of a 20 per cent. solution into my gum over my front teeth, and placed a wedge of hickory wood between them, and drove it in with a dentist's hand-mallet, at the same time driving the wedge against the gum between the teeth. I left the wedge there for twenty

Digitized by Google

minutes, and then slowly dragged it down between the teeth. The whole of this was done with very little discomfort, and had I a tooth that wanted removing I should be content to have it removed after the injection of cocaine."

THE SHAW-STREET HOSPITAL FOR WOMEN, LIVERPOOL.

THE annual meeting of the governors and supporters of the Hospital for Women, Liverpool, was held on the 3rd inst., the attendance of subscribers being very large. Mr. T. A. Bushby presided, and after a few preliminary remarks, in which he referred to the inquiry into the practice of the institution which has taken place since the last annual meeting, called upon the secretary, Mr. M. Guthrie, to read the report of the past twelve months' work. From this it appeared that, in spite of the disturbed state of affairs which has recently prevailed in the hospital, its general usefulness has been proved. The number of in-patients was 239 and of dispensary patients 3505. The expenditure during the year was £1759, being £47 less than in the previous year; but as there was in 1885 a deficiency of £88, the total expenditure came to £1647. Against this there was received the sum of £1074, showing a deficiency of upwards of £770. The medical board, in their fourth annual report, announce a decrease in the work done in the hospital and dispensary in the past year as against 1885, the number of in-patients showing a decrease of 108 and the out-patients a decrease of 6. To this report tables were appended which showed that of the 239 in-patients 104 were submitted to operation. Of this number 64 were minor operations, with no mortality; the remainder were major operations or abdominal sections, and resulted in a mortality of 10. This report and the balance-sheet were then adopted, and votes of thanks to the various visitors to, and officials of, the hospital proposed and carried. The appointment of the honorary medical staff was then proceeded with, and Dr. Briggs was, upon the motion of Mr. Tinne, unanimously reappointed.

Mr. LANCASTER proposed the re-election of Dr. Burton, who, he stated, had been connected with the hospital ever since its foundation; his practice as a surgeon had never been called into question; he had maintained a moderate course; he had invariably consulted according to the rules of the hospital; and he had not in a single instance brought upon himself the condemnation or the criticism of the members of the medical profession in Liverpool and elsewhere who had thought fit to criticise the operations of the other members of the medical staff.

Mr. BIRKETT seconded the proposition.

Mr. TINNE opposed Dr. Burton's re-election. He had no objection to Dr. Burton as an individual, but he considered that it would be for the interests of the hospital that the whole of the old staff should not be re-elected at that meeting.

Mr. S. S. BACON opposed, and Mr. W. OULTON supported, the proposition, and ultimately, after a few remarks from the chairman respecting the reasons which had led to the proposal of names separately, and not, as in former years, *en bloc*, a vote was taken, and Dr. Burton was declared re-elected by thirteen votes to nine.

Mr. C. JONES moved that Dr. Imlach be re-appointed as honorary medical officer of the institution. After having briefly reviewed Dr. Imlach's connexion with the charity from its foundation down to the close of the inquiry which was held last year, Mr. Jones contended that, on the strength of the report of the investigation committee, they could not dismiss Dr. Imlach—a contention which he supported by several quotations from the report. He hoped that they would not permit the great injustice of turning away one man who had done so much for the success of the hospital.

Mr. W. B. HALHED seconded the motion, and contended that in the special report of the Medical Institute there was no implication that Dr. Imlach should be turned out of the hospital. If they had wished that course adopted, he was sure that they would have said so.

Mr. GUTHRIE having opposed the motion, Mr. LANCASTER defended the Inquiry Committee, and maintained that in its deliberations no hostility was shown to Dr. Imlach or to any member of the medical staff of the hospital.

The voting then took place, when sixteen hands were held up in favour of the reappointment of Dr. Imlach and seventeen against.

Mr. C. JONES demanded a poll on account of the proxies. This was granted, and resulted in the rejection of Dr. Imlach by 272 votes to 137.

Some formal business was then transacted, and an adjournment of the meeting for the consideration of several alterations in the rules was carried. Previously, however, to the termination of the proceedings the Rev. D. MOUNTFIELD proposed a vote of thanks to Dr. Imlach, who had, he considered, been very badly treated. Mrs. ALFRED BOOTH also spoke in favour of Dr. Imlach, but the proposal was not put to the meeting.

ARMY MEDICAL SCHOOL, NETLEY.

THE fifty-third session of the Army Medical School at Netley was brought to a close on the 7th inst., when General Sir Donald M. Stewart, Bart., G.C.B., G.C.S.I., &c., late Commander-in-Chief of the Forces in India, presented the prizes gained during the term by the surgeons on probation. Sir Donald, in some remarks to the students, criticised the system at present in force in the British service, which in his opinion has one main defect—viz., the absence of any direct connexion between the medical service and regiments.

Sir JOSEPH FAYRER then announced the gift of about 350 separate works, comprising between 600 and 700 volumes, to the library at Netley School, by Dr. Waring, late of the Madras Medical Service. The collection, he stated, was specially rich in works on Materia Medica, and others dealing with foreign countries, besides several rare books of medical bibliography.

Sir THOMAS CRAWFORD thanked Sir Donald Stewart for having consented to present the prizes, and congratulated the students who had gained their commissions on the way in which they had worked through the past session, concluding by most heartily wishing them every success in the future.

Sir THOMAS LONGMORE expressed similar good wishes for the prosperity of the medical officers on behalf of the professors under whom they had studied, and the proceedings then terminated.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

West Sussex Combination.—Dr. Charles Kelly's report for 1885 reached us somewhat late. Of the eleven districts which compose it, the lowest rate of mortality was in the small district of West Worthing, where it stood at 7·8 per 1000, the highest being 16·6 in the Westbourne rural district These rates have, however, varied much during a series of years. Viewing the whole combined districts the death-rate has diminished from a mean rate of 15·4 per 1000 in the five years 1876-80, to 14·4 in the subsequent period of five years. There has been a rise in the diphtheria death-rate in this district. Taking the whole of England that rate stands at 121 per 1,000,000; in West Sussex it now reaches 170 per 1,000,000, and it is, as elsewhere, more inclined to be fatal in rural and semi-rural places than in towns. Thus, in Brighton the rate is 81 per 1,000,000, whereas in Petworth it is more than five times, and in Horsham more than three times, higher. But there are differences even in the same district, and Dr. Kelly has made it a special care to examine the influence of soil as regards this and other mortalities. The result is that he has found that the death-rate per 1,000,000 from diphtheria, being 246 on his entire area for a period of ten years, was no less than 454 on the retentive soils such as the Weald clay, the clayey beds of the lower green sand, and the gault; and only 127 on such pervious soils as the upper and lower green sands, the chalk, and the lower Tunbridge Wells sands. The influence of soil in the production of this mortality is the more striking because it appears so entirely to outweigh that which is brought about by personal inter-

Digitized by Google

communication, which, one would have imagined, would in towns have so greatly exceeded that which obtains in rural areas. These and similar contributions to our knowledge of the etiology of disease come most appropriately from medical officers of health acting for wide areas, and they add special interest to their reports.

Huddersfield.—Dr. Spottiswoode Cameron in his report on the fourth quarter of 1886 points out that although, speaking generally, Huddersfield compares well as regards infectious diseases with the twenty-eight large towns and cities quoted by the Registrar-General, yet the rate of mortality in the borough from diphtheria has been half as much again as in the towns referred to, and that the rate from whooping-cough was three times that with which it is compared. Diphtheria is essentially a disease to be dealt with by early isolation of first attacks, and though some cases are received into the Birkby hospital, yet this sanitary institution is, notwithstanding excellent additions to it, not sufficiently complete to deal with this disease. Whooping-cough is, unfortunately, a disease which is at present almost beyond the scope of sanitary measures.

Salford.—Dr. Tatham, in reporting for the last quarter of 1886, finds it necessary to issue a warning as to the spread of scarlet fever in his district; this spread being largely due to deplorable carelessness. Of 603 cases reported to the Health Department during the quarter, 307, or 51 per cent., were removed to the infectious hospital. This is very satisfactory, but unless those responsible for the remaining 49 per cent. take note of the warning issued, especially as regards children during the school age, scarlet fever will continue to spread. The numbers of those attacked during the past four quarters have been 177, 230, 550, and 603 respectively. It is certainly time for the inhabitants to aid the health officers in controlling this scourge.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5846 births and 3470 deaths were registered during the week ending Feb. 5th. The annual death-rate in these towns, which had declined in the preceding four weeks from 26·5 to 21·1 per 1000, further fell last week to 19·6. During the first five weeks of the current quarter the death-rate in these towns averaged 22·8 per 1000, and was 1·9 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·5 in Nottingham, 13·7 in Brighton, 16·3 in Norwich, and 17·1 in Birkenhead. The rates in the other towns ranged upwards to 25·0 in Preston, 25·3 in Bradford, 26·3 in Manchester, and 28·4 in Plymouth. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 485, 392, and 371 in the preceding three weeks, further declined last week to 367; they included 111 from whooping-cough, 104 from measles, 54 from scarlet fever, 40 from "fever" (principally enteric), 29 from diphtheria, 27 from diarrhœa, and 2 from small-pox. These principal zymotic diseases caused the lowest death-rates last week in Nottingham, Cardiff, and Wolverhampton; and the highest rates in Bristol, Plymouth, and Blackburn. The greatest mortality from whooping-cough occurred in Bradford, Sunderland, and Plymouth; from measles in Bristol and Newcastle-upon-Tyne; from scarlet fever in Salford, Sheffield, Blackburn, and Birkenhead; and from "fever" in Plymouth. The 29 deaths from diphtheria in the twenty-eight towns included 16 in London, 3 in Portsmouth, 3 in Liverpool, and 2 in Preston. Small-pox caused 1 death in Manchester and 1 in Blackburn, but not one in London and its outer ring, or in any of the twenty-five other large provincial towns. Only 1 small-pox patient was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding four weeks from 731 to 432, further declined last week to 364, and were 279 below the corrected average. The causes of 75, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Nottingham, Leicester, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Oldham, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·7 and 24·7 per 1000 in the preceding two weeks, declined to 19·8 in the week ending Feb. 5th; this rate exceeded by 0·2 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 12·2 and 14·6 in Leith and Perth, to 21·3 in Aberdeen and 23·7 in Glasgow. The 495 deaths in the eight towns last week showed a decline of no fewer than 121 from the numbers in the previous week, and included 23 which were referred to whooping-cough, 12 to measles, 10 to "fever" (typhus, enteric, or simple), 8 to scarlet fever, 7 to diphtheria, 6 to diarrhœa, and not one to small-pox; in all 66 deaths resulted from these principal zymotic diseases, against 65 and 75 in the preceding two weeks. These 66 deaths were equal to an annual rate of 2·6 per 1000, which exceeded by 0·5 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had declined in the preceding five weeks from 27 to 19, rose again last week to 23, of which 17 occurred in Glasgow, 3 in Edinburgh, and 2 in Paisley. The 12 deaths from measles showed a decline of 6 from the number in the previous week, and included 9 in Glasgow and 2 in Aberdeen. The deaths referred to "fever," which had been 5 and 6 in the preceding two weeks, further rose last week to 10, of which 5 occurred in Glasgow, 2 in Edinburgh, and 2 in Greenock. The 8 fatal cases of scarlet fever, on the other hand, showed a considerable further decline from recent weekly numbers, and included 4 in Edinburgh and 3 in Glasgow. The 7 deaths from diphtheria, of which 4 occurred in Glasgow, corresponded with the number in the previous week. The 6 deaths attributed to diarrhœa, showed a decline of 4 from the number in the previous week. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had steadily declined in the first four weeks of the year from 213 to 155, further fell last week to 126, and were 9 below the number returned in the corresponding week of last year. The causes of 76, or more than 15 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 36·2, 32·2, and 28·2 per 1000 in the preceding three weeks, rose again to 29·7 in the week ending Feb. 5th. During the first five weeks of the current quarter the death-rate in the city averaged 31·5; the mean rate during the same period being but 21·8 in London and 21·4 in Edinburgh. The 202 deaths in Dublin last week showed an increase of 10 upon the number returned in the previous week, and included 4 which were referred to scarlet fever, 3 to whooping-cough, 3 to diarrhœa, 2 to "fever" (typhus, enteric, or simple), 1 to diphtheria, and not one either to small-pox or measles. Thus the deaths from these principal zymotic diseases, which had been 21, 13, and 14 in the preceding three weeks, were last week 13; they were equal to an annual rate of 1·9 per 1000, the rates from the same diseases being 1·8 in London and 2·0 in Edinburgh. The fatal cases of scarlet fever, whooping-cough, and "fever" showed a decline from the numbers in the previous week, while those attributed to diarrhœa were more numerous. The deaths of infants exceeded the number returned in any previous week of this year, while those of elderly persons showed a further decline. Seven inquest cases and 8 deaths from violence were registered; and 54, or more than a quarter, of the deaths occurred in public institutions. The causes of 32, or nearly 16 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Surgeon-General E. G. M'Dowell, of the Army Medical Staff, has been appointed Principal Medical Officer at Halifax, Nova Scotia.

Messrs. Wilkins, Patterson, Venour, North, and Dr. Ogilvie (all Surgeons-Major) have been appointed Senior Medical Officers to Brigades in Upper Burmah.

Mr. C. W. Owen, C.I.E., M.R.C.S., L.R.C.P., who was with the Afghan Boundary Commission, was recently presented by the Amir with an autograph letter thanking him for

Digitized by Google

the good work which he had done in the medical treatment of Afghan officials and other subjects of the Amir.

ADMIRALTY.—The following appointments have been made:—Surgeon James J. Walsh, to the *Vernon*, additional; Mr. John V. Laverick, to be Surgeon and Agent at Skinningrove, Staitho, Runswick, Kettleness, and Hammersen.

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Loyal North Lancashire Regiment: Surgeon and Honorary Surgeon Major R. Settle, M.D., resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement.

VOLUNTEER MEDICAL STAFF CORPS.—The Woolwich Division: William Collingridge, M.D., to be Surgeon (Supernumerary).

Correspondence.

"Audi alteram partem."

GENERAL HOSPITALS AND PARISH INFIRMARIES.

To the Editors of THE LANCET.

SIRS,—I agree entirely with the letter of your correspondent "X.," published last week, but I would go much further than he. It has always seemed to me, more particularly so in these days of hospitals partially closed for want of funds, that it is an injustice to the ratepayer to have built, and to compel him to keep up, the magnificent parish infirmaries which one may see now in the north, south, and west of London. It would surely have been no difficult matter in the case of many parishes to have subsidised the nearest general hospital, and thus to have commanded beds sufficient, at any rate, for all urgent cases of disease. And if it be objected that none of the existing hospitals could have provided sufficient accommodation, I should reply that it would have been better far to extend the already existing general hospitals, and, if need be, to build others in quarters where they were needed, than that each parish should have launched out into bricks and mortar to the extent that has been done with completely equipped establishments. It used to be the custom at Guy's, I know, to receive parish cases at so much per week, but few such are, I think, admitted now; and I am told, that in some of the large continental towns a small sum per diem is paid for each patient admitted, unless he be selected and consent to occupy a bed in the wards devoted to special clinical cases. It is difficult to see what insuperable difficulty there could have been, or would be now, with an ever-growing population, in adopting some general plan of this kind. But I venture to maintain that these large parish infirmaries are not only an injustice to the ratepayers—I do not think I should take up a pen on that score; they also do harm to the general hospitals; and, in a sense, I think it may be fairly said that they may do injustice to the patients that are admitted within their own doors. I have been told by more than one surgeon at the metropolitan hospitals that a great number of surgical cases are now diverted by the parish infirmaries. It is evident that it must be so. First-class men seek and obtain the resident appointments at these institutions, and they are not content—why should they be?—to treat only the very chronic and incurable cases; they operate on hernias, amputate limbs and breasts—in fact, do anything within the range of trodden or untrodden medicine or surgery; and as a result the practice in general hospitals is curtailed, the students suffer to a very definite extent, and again, since it is a very clinching argument, the rates are necessarily increased. Surgical skill and appliances, the latest novelty in drugs, cannot be had for nothing; and the advanced medicine and surgery (particularly the latter) of the present day are admittedly very expensive. I submit that the ratepayers are not called upon to undertake this expense until the general hospitals are unable to meet the demand, and it is safe to assume that in the present impecunious state of these, and with their many vacant beds, it could be done cheaper and more helpfully by them than the parishes can do it in their own infirmaries, when the cost of building, staff, &c., is taken into account. It may also be said that to turn the parish infirmary into a general hospital, as is done in the present day, is unjust to many of the patients.

This might seem at first a delicate matter to touch upon, but it is no more than common sense after all. Everyone will probably allow that the advanced surgery of the present day—I speak as a physician might be expected to speak!—should always, in the interest of the patient, be a matter of free consultation. Success is happily often the crown of what at the outset is but a desperate venture to the patient, and even to the surgeon hardly more than a forlorn hope, with forlorn writ very small and hope unusually big. But it is the desperate venture that requires the more consideration, and the fastest express requires the most perfect possible of brakes. Again, it is quite impossible in the present day that the one or two (able men as they are) resident medical men can work a large general hospital—such as, in fact, these institutions are becoming,—and this has of late been recognised in the proposition which has been made, that they should have a consulting staff attached to them. But I do not think that this meets the requirement. Honorary consulting physicians and surgeons are for the most part illusions, and to my mind a largely increased acting staff is what is necessary. By this means alone can any free consultation, the discussion of opinions and of proposed measures of treatment in critical cases, be guaranteed as a matter of routine. I live in hope that somehow or other, at some not far distant day, the present parish infirmaries may be linked each to its nearest general hospital, and that both will be in some measure aided by the rates. I feel sure that economy and efficiency would gain thereby, and that thus the real want of hospitals and infirmaries would be mutually supplied.

I am Sirs, yours obediently,

Weymouth-street, W., Feb. 5th, 1887. JAMES F. GOODHART.

THE CAMBRIDGE CHOLERA FUNGUS.

To the Editors of THE LANCET.

SIRS,—In a recent issue (Jan. 20th) of your contemporary *Nature*, Mr. Gardiner, who had previously suggested that the so-called Cambridge cholera fungus might be a Chytridium, has withdrawn that opinion, and now believes it to be the involution form of some bacterium. He further adds that this organism very vividly recalls to his mind the involution form assumed by Bacterium cyanogenum. I should like at once to point out that this later opinion bears out to a certain extent the conclusion which I arrived at last year. This I have expressed in the new edition of my Manual of Bacteriology, which will be issued, I hope, in a few days, as follows:—"At a meeting of the Physiological Society, May 15th, 1886, at Cambridge, a preliminary communication was made upon the investigations in Spain, referred to in the first edition of this work. The observations made by Roy, Brown, and Sherrington, rather tend in the opinion of the author, to confirm Koch's views. Comma bacilli were found to be present in some cases in enormous numbers, and the frequency of their occurrence led these observers to believe that they must bear some relation to the disease. At the same time, as they failed to find them in all cases, they regarded the existence of a causal relation as not proved. They failed to find the Naples bacterium or the small straight bacillus noted by Klein, but they drew attention to certain peculiar mycelium-like threads in the mucous membrane of the intestines. This organism, however, judging from a preparation stained with methylene blue, which was exhibited at the meeting, appeared to the author to much more closely resemble some of the involution forms of the comma bacillus, *filaments à masses globuleuses*, figured by Van Ermengen than anything else he had seen. Yet, assuming that these peculiar structures do belong, as described, to some species of Chytridiaceæ, it is very doubtful whether they can be considered to be of any significance. Methylene blue has been employed by Koch and others, including the author, for staining sections of the intestine from cholera cases, and had these structures been constantly present it is hardly possible that such striking objects could have been overlooked. Again, we must bear in mind that hyphomycetous fungi occasionally have been found to occur saprophytically in the intestinal canal, the lungs, the external auditory meatus, and elsewhere. We must, however, wait before expressing a more decided opinion until the report of these observers is published in full."

I have now before me the proceedings of the Royal

Digitized by Google

Society (No. 247), an abstract of which was given in your issue of Jan. 29th, and I must confess that I am much puzzled by the illustrations which accompany the preliminary report on this subject. These figures, as Dr. Klein has pointed out, certainly appear to represent a branched mycelium, but they do not in the least recall to my mind the actual preparation which I had an opportunity of examining, and upon which I founded my opinion in May last. It has occurred to me that possibly Mr. Gardiner was shown the very same preparation, and hence his recent opinion that this organism is some involution form.

With regard to methylene blue having been used by Koch, I would refer those interested in this discussion to "Bacteriology," p. 141, where the method is given, as reported in the *Berliner Klinische Woch.*, No. 31 (Conferenz zur Erörterung der Cholerafrage, Juli 26, 1884). In their preliminary report, Messrs. Roy, Brown, and Sherrington state that the particular method they employed was almost identical with that of Löffler, and they add, "So far as we know, Löffler's method has not been employed to stain sections of tissues taken from fatal cholera cases," but here I must add that Löffler's method was precisely the one which I used in staining a great number of sections in July, 1885, as it had been especially recommended for that purpose by Dr. Workman in the *British Medical Journal*, No. 1280. I am Sirs, yours faithfully,

EDGAR M. CROOKSHANK, M.B.

Manchester-square, W., Feb. 3rd, 1887.

THE FUTURE UNIVERSITY OF LONDON.

To the Editors of THE LANCET.

SIRS,—In your excellent article replying to the writer in the *Quarterly Review*, you enumerate University College, King's College, the Science and Art Schools at Kensington, the Technical Institute of the City Guilds, the Royal Colleges of Physicians and Surgeons, and the Inns of Court as bodies which are not, but might be, incorporated in a true University of London. Will you allow me to ask for a reconsideration of this position? It is of immense importance that the wrong ingredients should not be mixed to form the new University. As nearly as circumstances will allow, we want *one* body of professors actually united and organised as a single corporation of teaching examiners or examining teachers to constitute the new University. The attempt which has been made by Sir George Young and one or two members of an Association which has never itself assented to such a scheme—to bring individuals from diverse and very many teaching institutions together as the basis of a new University—is, I venture to assert, a fatal error. A certain small amount of popular support may be obtained for the new University movement by thus widely throwing the net, but it is at the sacrifice of all that is worth obtaining in the foundation of a new University. The Normal School of Science has no *locus standi* in the matter. Its business is to train school teachers and to grant its own certificates. Its lecturers are paid by the taxpayers. The Technical College similarly must stand on its own bottom and grant its own diplomas, and has no claim whatever to take part in the University. Leaving aside for the moment the question of professional degrees in law and medicine, it results that for the general purposes of University training and the granting of degrees in Arts and in Science there are only two bodies in London which can claim the concession to their professors of the special favour and privilege in question. These two bodies are University and King's Colleges. The mere fact that there are *only* two such bodies is immensely important; it results in an absolute certainty that were these two bodies endowed by the Crown with the style and authority of a university, they would gradually fuse with one another and become a single corporation identical with the University. Thus we should at last see in London one powerful and authoritative body of teachers able to claim and to attract endowments whilst teaching and carrying on research on a scale worthy of the richest city in the world. The professional degrees in Law and in Medicine must, I admit, be placed on a somewhat different footing; and in the new University the Faculty of Law and the Faculty of Medicine should consist not of the professors of these subjects in the University and King's College, but of representatives of the professions of law and of medicine generally. This distinction is necessary for several reasons, but chiefly because in the case of medicine the degree has a special professional significance, and because the teaching of medicine and surgery, strictly so called, is splendidly provided for by the great London hospitals and tested by the great medical corporations. There may be a reluctance on the part of the Crown to grant the power of conferring what would purport to be an academical degree to a purely professional corporation. If so, the objection might be removed by making the new body—whatever its internal constitution may be—which is to confer the degree of M.D. on London students occupy the position of the Medical Faculty of the new University whose Faculties of Arts and of Science are formed by the professors of University and King's Colleges. It will be objected to these proposals that special privilege and favour are to be accorded to University and King's Colleges. But why should such favour not be granted to them? The essence of university foundations is the grant of a privilege of dignity and authority to a selected body. No one can maintain for a moment that University and King's Colleges are not worthy to receive this privilege, or that there is any other body in London which has any claim, except in regard to medicine and law, strictly so called, to share it.—I am, Sirs, your obedient servant,

E. RAY LANKESTER, M.A., LL.D., F.R.S.

Savile Club, Piccadilly, W., Feb. 7th, 1887.

*** We did not instance these institutions as constituent bodies in a new university, but merely to show that the existing University had done nothing to bring them into any closer union than was the case with corresponding institutions in the time of Stowe.—ED. L.

ON THE CAUSE OF MARKED HYPERTROPHY OF THE ANTERIOR WALL OF THE BLADDER.

To the Editors of THE LANCET.

SIRS,—At the meeting of the Pathological Society on the 18th ult., Mr. Fenwick drew attention for the first time to the fact that the anterior wall of the bladder hypertrophies much more than the remainder, especially in cases of unrelieved stricture of the urethra. The position of the bladder in the anterior part of the pelvis enables it, when dilated, to expand posteriorly in the direction of the rectum and upwards into the abdominal cavity, but the pubic wall flattens the anterior surface. This affords the true explanation of the phenomenon. If membranes in the shape of spheres of varying sizes enclose fluid, so that the tension is uniformly distributed along each fibre, the thickness of the membrane must by the principles of hydrostatics be exactly proportional to the radius of the corresponding sphere. Similarly it follows that the greater the flattening of the anterior wall of the bladder as compared with the curvature of the posterior and upper walls, the greater must be its thickness, in order that the pressure of the urine in the bladder may be balanced by the same tension of each muscular fibre. Hence the diminished curvature of the anterior wall of the bladder throws a proportionate increase of work on that part of the wall, and a greater thickening ensues. This is, in fact, an illustration of the general law in physics—that every limitation to the free movement of a body throws an increased strain upon the body: the pubic wall impedes the projection of the bladder forwards, and therefore throws an increased strain upon its impeded portion, the anterior wall, and this completely explains the localised thickening to which Mr. Fenwick has drawn attention. I am, Sirs, yours truly,

Jan. 19th, 1887. G. N. PITT.

THE LAW RELATING TO CORONERS.

To the Editors of THE LANCET.

SIRS,—As I have made a public promise, of which you have been kind enough to take notice, that I should bring in a Bill to amend the law relating to the election of coroners in English counties, I wish, if you can give me space in your valuable columns, to explain why I have not

Digitized by Google

been able to fulfil that promise. I did draw up such a Bill, in which I proposed that the freeholders on the Parliamentary Register for the time being should be the electors. On consultation with several of my Radical M.P. friends, with whom I generally act, I find there is an objection on their part to conferring any special benefits on the freeholders, and they prefer that the whole of the voters on the Parliamentary Register should be the electors. This I find impossible, as the numbers which would have to be dealt with would be so large as to be practically unworkable. Another objection taken is that the freehold portion of the present Parliamentary Register will within a few years be done away with, on the principle of "one man one vote," and that it would not be likely to be kept on for the election of coroners only. It is also objected that the election of coroners for counties should be put in the same category as that for towns, which is vested in the town councils, and should in the former case be delegated to the county local boards, which are likely to be established during the present session of Parliament. Failing the support of the gentlemen with whom I usually act, I have given up the subject in despair, and written to one of the Middlesex magistrates for the information of the Bench, stating these reasons for not bringing in the promised Bill. I have always been of opinion that every coroner should be in the first place a medical man, and that an examination in the law of evidence, similar to that in State medicine, should be set on foot, in order that every medical man who aspires to be a coroner should be able to shew by passing it that he is doubly and fully qualified to discharge the duties of such a responsible post. Your powerful advocacy of such a proposition would soon bring it within the range of practical politics, and confer a great boon on the medical profession. Barristers or solicitors who hold a double medical qualification would in this case also be eligible for the post.

I am, Sirs, yours truly,

Millwall, Feb. 8th, 1887. R. MACDONALD, M.D., M.P.

LISTERIAN AND NON-LISTERIAN OVARIOTOMY.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 27th, 1882, there appeared an editorial note on the results of ovariotomy at the Samaritan Free Hospital in the year 1881, contrasting the results under the Listerian and non-Listerian methods of operating, and I shall be obliged by your allowing me to recall attention to the subject. In the note referred to you pointed out that the mortality under the Listerian method was very much less than that under the non-Listerian in my hands, but, unlike your contemporaries, you were careful not to draw any conclusions from the data. In the following number (June 3rd) you were good enough to publish a note of mine, in which I asked you to suspend your judgment, on the ground that it was "a very unsafe proceeding to lay too much stress on any particular series of cases, and especially on those of one year only." The reasonableness of that request will be apparent when I bring to your notice the results of the same operation during the year just past (1886), for they completely upset the fanciful conclusions derived from the results of 1881. Thus, in the year 1886 there were forty-six ovariotomies performed in the Samaritan Free Hospital by three operators, with a careful observance of all the details of the Listerian method, and of those cases seven died; while the twenty-five cases done by me without any so-called antiseptic precautions, beyond the strictest attention to cleanliness, *all recovered.*

I offer no comment, and have only to request that you will give the same prominence to this statement as you gave to that to which I here recall your attention. As the results of the work done in the Samaritan Free Hospital will not be published in the form in which they appeared in 1882, and as there will be no means of judging between the merits of the two systems in future reports, I beg to enclose the precise data for your own use.

I am, Sirs, yours faithfully,

Granville Pl., W., Feb. 9th, 1887. GEO. GRANVILLE BANTOCK.

THE FELLOWS AND MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—As the Association of Members of the Royal College of Surgeons is now taking the preparatory steps for the immediate presentation to the Privy Council of the petition which you kindly noticed in your journal about a month ago, it may interest your readers to know that we have obtained the large number of 4590 signatures of Members of the College to the same. The old taunt of the Council of the College that "some Members" only were desirous of this change in the election of the Council is thereby set at rest once and for all, for this is a very large proportion indeed of the whole number of the Members of the Royal College of Surgeons, and much larger than it seems at first sight, the calculation of the officials of the College as to the number of its own Members being hopelessly at fault. We find, and till the other day we had accepted this as correct, that the College Calendar gives a "list of Members" totalling 17,040, and most men would have thought that that was very nearly accurate. But upon reading three weeks ago that the College authorities had only sent out 987 polling papers to its Fellows, whose numbers appear on the Calendar as 1124, it occurred to us that a similar discrepancy between the actual and the *official* numbers of the Members might also exist. Nay, we expected, as we have found, a still greater difference; for whereas the Fellows are honoured by what calls itself an "Alphabetical Register," the poor Members are put off with only a "list." The distinction is most subtle. However, it may be presumed that the word "list" was chosen as not committing its promulgators to an endorsement of the accuracy of its contents. Now, we have gone most carefully through the Medical Register for 1886, published only four months before the last College Calendar, and find that the number of Members of the College upon it is only 11,821, which, to allow for errors in casting, we will call 12,000—that is to say, that five-seventeenths, or nearly a third, of the Members exist only upon that list, or in the imagination of its compilers. They *have* existed, it is true; but the College clings fondly to their memory, and mutters still, as Wordsworth's peasant child, "We are seven"-teen thousand! That our calculation is, in the main, correct is proved by an analysis of a sample of this "list." On page 89 we find 98 names of Members; of these, only 61 are on the Medical Register, to which we must add 2 who qualified in the interval between its publication and that of the Calendar, thus leaving 37 names of Members whose ghosts still linger round the College walls, awaiting the burial of their diplomas. We trust you will pardon this digression, but it is of importance with regard to the weight that the sum of these signatures should carry. That out of 12,000 Members of the Royal College of Surgeons, of whom a good 2000 are inaccessible, 4600 should have actively identified themselves with this movement by their signature should have great influence with the profession and with the Privy Council. We may, in conclusion, add that every signature is by a *bonâ fide* M.R.C.S., for we have checked each in the Medical Directory for 1887, and thus eliminated not only men who had signed before, but those few who signed in error, not holding the College qualification. We hope later to be able to give you a few local and other details of the signatures. We are, Sirs, your obedient servants,

WARWICK C. STEELE, } Hon. Secs., Assoc.
WM. ASHTON ELLIS, } of M.R.C.S.

Western Dispensary, Westminster, S.W., Feb. 9th, 1887.

A CURIOUS LACRYMAL CASE.

To the Editors of THE LANCET.

SIRS,—The following case, which in my experience I am glad to say is unique, deserves a passing record.

On Saturday, Jan. 29th, a young man came to my clinic. The whole of the right side of his face was considerably swollen, puffy, and covered with scabs in places. About half an inch below the lower lid in the angle formed by the cheek and the nose, but far removed from the position of

Digitized by Google

the lacrymal sac, these crusts become unusually thick, and projecting from their centre was visible the upper extremity of a hollow silver lacrymal style. Struck by its unusual position, I began to seek for the distal extremity. This was found in the mouth between the gums and cheek, just above the socket of the right canine tooth. It had not perforated the mucous membrane owing to the discharge produced by its irritation having found exit through the cheek, but it could easily have been pushed through had it been of sufficient length. Any movement communicated to the cheek moved the whole tube *in situ*, and it had obviously never been in the proximity of the lacrymal apparatus or nasal duct. The way the operation must have been performed was no doubt as follows: The supposed position of the lacrymal sac having been determined, an incision through the skin was made over it. The subcutaneous structures having been reached, the style was pushed downwards, passing in front of the superior maxilla below the whole thickness of the cheek, and was there left. The tube had been in its present position for fourteen months, and it is needless to say the slight lacrymal obstruction which it was intended to have cured had derived no benefit. The case was seen by Dr. Davies, Mr. Wicks, Mr. Brewis, and other gentlemen who kindly assist at my clinic.

I am, Sirs, yours truly,

C. S. JEAFFRESON,
Sen. Surg. Northumb. and Durh. Eye Infirm.

Newcastle-on-Tyne, Jan. 29th, 1887.

EPIDEMIC DIARRHŒA.

To the Editors of THE LANCET.

SIRS,—In reference to your article in THE LANCET of last week, concerning our London water-supply as a possible source of distributing disease the following particulars may be of interest.

During the last four weeks the casualty and out-patient departments of the West London Hospital have been called upon to attend to an extensive outbreak of a severe form of diarrhœa. The cases have been very numerous, far exceeding those met with during the summer months, and also exceeding those in the severity of the attack. The symptoms in nearly all the cases have been sudden pain in the epigastrium, vomiting, incessant diarrhœa with (in a few cases) bloody stools, a rise of temperature (100·5° to 101·5°), followed by extreme prostration, and in two cases collapse. The duration of the attack has been from three to eight days. The districts affected were those of Fulham, Chiswick, and Hammersmith—an area too large for any common cause save those of atmosphere and water-supply.

I am, Sirs, yours truly,

CHAS. H. TAYLOR,
West London Hospital, W., Feb. 7th, 1887. House-Physician.

FRIENDLY SOCIETIES' MEDICAL ASSOCIATIONS: VIEWS AND EXPERIENCE OF A MEDICAL OFFICER.

To the Editors of THE LANCET.

SIRS,—Before entering a Friendly Societies' Medical Association, in which I stayed several years, I had no knowledge of such institutions, but thought they partook of the character of dispensaries and adapted for the necessities of the working classes of limited means. In this I was soon undeceived, and found it to be composed of an amalgamation of friendly societies' clubs within a radius of three miles, who sent delegates, one for each hundred or part of a hundred of its members, to form a general committee, who again appointed from their numbers annually a committee of management, consisting of president, vice-president, secretary, treasurer, trustees, three auditors, and nine members, the secretary and auditors being paid for their services. The managing committee, seven of whom formed a quorum, sat once a month, the general committee once a quarter, except under special circumstances. The medical officers were appointed by the general, after being selected by the managing committee, the senior medical officer living on the society's premises, having to sign an agreement, stringent in its particulars, such as to finding all surgical instruments, not to absent himself from work either through illness or otherwise, unless supplying his place by a duly qualified practitioner as substitute, not to practise within four miles of the town, under a penalty of £100, except he has served the society five years, there being no equivalent if he is given, with or without cause, three months' notice as by agreement. The objects of the Society were to supply certificates, examine candidates for the various societies, give advice and medicines, and to visit within a radius of three miles members at their own homes. The hours of the dispensary were from 9 to 10 morning, 1 to 2 afternoon, and 6 to 8 evening, the rest of the day being consumed by visiting the sick and attending midwifery if forthcoming. For visiting, except in cases of emergencies, notice had to be left at the dispensary before 10 A.M. This rule was never strictly carried out. Sunday, although supposed to be a day of rest, the visiting, &c., only being in cases of sudden illness, yet members would worry on that day more than any other, and that from morning till night. The only holidays in the year were Christmas Day and Good Friday, if nothing happened. The medical staff of the Society, which numbered about 4000 members, consisted of one resident, and one non-resident, there being no dispenser. The members, their wives and children, also lodgers and relatives over eighteen, and living under the same roof, paid 1*s.*, and children and others under eighteen years of age paid 6*d.* per quarter, accouchements 10*s.* 6*d.*, vaccination free. Juvenile members of the various societies could include in the benefits of the Association their parents, grandfathers, &c. Members were composed of tradespeople (some in good circumstances), clerks, artisans, and labourers, also retired individuals of various callings. Often the attendance at the surgery came to 100, sometimes 180 in the day, not counting the visits at the patients' homes. Calls for visits were frequently required for most trivial complaints. Abuses on the members' part are taken no cognisance of, in fact, no rule applied to any such charge against a member, but two rules applied to complaints made by a member or his family against the medical or other officers.

The salaries of the medical officers were the following: Resident, £180; non-resident, £120. Extras, midwifery fees paid to the officer attending, at first, 8*s.* 6*d.*, afterwards 10*s.* 6*d.*, the 2*s.* being allowed for out-pocket expenses to drivers when going long distances, cabs being on contract terms. An allowance at first of £10, then £15, per annum to resident medical officer for coals, gas, cleaning, &c., this applying to waiting-room, used also for auditors, managing committee meetings, and others; also supplying gas to surgery, consulting-room, lamp to gate, &c. Formerly, what the club doctor lost through the members he gained by the families. Now, under the Association plan, not only the families of the poorer, but those of the well-to-do portion of the members belong to it, thus seriously affecting the medical interests, as instead of about £700 being the annual receipts, as in the Society to which I belonged, and then not all paid to the medical staff under the old system, at the lowest estimate three times as much would accrue from the same numbers, and would all go to the medical profession. I am, Sirs, yours faithfully,

Feb. 8th, 1887. SURGEON.

SURGICAL TREATMENT OF HYDATID CYSTS OF THE LIVER.

To the Editors of THE LANCET.

SIRS,—Permit me to make a short comment upon your leading article (Feb. 5th, 1887) on the Surgical Treatment of Hydatid Tumours of the Liver, which is founded on my paper and the ensuing discussion at the Medico-Chirurgical Society. You say that I "did not show that this escape of contents [hydatid fluid] has been a serious sequela of the operation as more usually performed." I even went further, stating that the escape of a small quantity of saline and usually non-albuminous fluid would not in the majority of cases set up septic peritonitis, that with this fluid, however, a certain number of scolices might be carried into the peritoneum, and give rise secondarily to hydatids more or less diffused in that cavity. I would, therefore, in view of both these possibilities, avoid any effusion of hydatid fluid into the abdominal cavity. The question appears to me to be not whether a certain number of operations, otherwise performed, have terminated favourably, but whether the procedure I have advocated avoids, as I contend it does, the dangers alluded to more surely and

Digitized by Google

completely than any other method. As for the supposed heavy price to be paid for this extra degree of safety by dividing the operation into two stages, I must point out that this price is *nil*, for the second stage consists merely of an incision not into the patient, but into an hydatid cyst. It presents itself as a detail of dressing; the parasite may perhaps feel the cut—the patient most certainly does not.

I am, Sirs, your obedient servant,

Feb., 1887. RICHARD BARWELL.

DR. BRUNTON AND HOMŒOPATHY.

To the Editors of THE LANCET.

SIRS,—You are quite right in your remark on Mr. Bateman's note that "it is not the use of any particular drugs that constitutes homœopathy"; but that is not all that we allege against Dr. Lauder Brunton in reference to his work on Pharmacology, &c. Dr. Brunton not only takes a large number of his drugs from the homœopathic materia medica, but he likewise takes his indications for the use of these drugs from homœopathic works. Where else could he derive his knowledge that pulsatilla is a remedy for acidity, diarrhœa, earache, and epididymitis; that bryonia is useful in pleurisy, pneumonia, meningitis, peritonitis, and rheumatism; that thuja is good for condylomata; viola tricolor and rhus toxicodendron for eczema; gold for ozæna; achillæa for uterine hæmorrhage; ignatia for hysteria, melancholia, infantile convulsions, and nervousness; and fifty other remedies and their indications strange to old physic? Dr. Brunton gives in his book a bibliographical index with lavish references about the medicines commonly used in your school, but not a single reference about the medicines which homœopathy has introduced into medical practice. Why is this? Did Dr. Brunton rediscover all these remedies and their indications for himself? I know Dr. Brunton is a very clever man who has made many experiments with drugs on many frogs, but if his researches in this field had taught him the above uses of these drugs, he would certainly have told us. So we are driven to the conclusion that Dr. Brunton has borrowed extensively from homœopathy, but has studiously withheld from his readers the source of these borrowings, and, for anything that appears to the contrary in his book, he assumes to himself all the credit of all these remedies and their indications, so strange to the practice of your school. Is this the right thing for a medical author to do? We may be a contemptible sect in the eyes of an orthodox author, but it is surely carrying cynical contempt for the rival school a little too far to "convey" a large number of their chief remedies into his book, and to conceal carefully the source whence he has taken them. Does not Dr. Brunton owe the profession some explanation of his extraordinary conduct.

I am, Sirs, your obedient servant,

London, Jan. 29th, 1887. R. E. DUDGEON.

INEQUALITY OF THE PUPILS IN VARIOUS DISEASES.—CAUTION IN THE ADMINISTRATION OF SALICYLIC ACID.

To the Editors of THE LANCET.

SIRS,—In your impression of last week I noticed amongst your annotations some remarks published by Dr. Pasternataki on the inequality of the pupil in certain diseases, and on careful reading I am surprised to note, although several diseases are mentioned where this phenomenon is observed, no allusion is made to its occurrence in tubercular meningitis. Now, as far as my experience goes, it is in this disease (especially in young children) that this symptom is frequently to be noticed, and is of great pathognomonic value, indeed pre-eminently so as regards diagnostic importance, where the signs of this disease are masked or obscure. I have never had a case where death has followed the diagnosis of tubercular meningitis without the inequality of the pupils having been a prominent and early symptom, so much so that I have been induced to exclude the diagnosis of this disease if this symptom is absent; and in every case that has resulted in recovery from, as I have thought, tubercular meningitis, this symptom was not present, and consequently I believed I had been mistaken in my diagnosis; and perhaps this is why I am very sceptical as to the recovery from genuine tubercular diseases of the membranes of the brain.

If it will not make my letter too long, I would wish to add I have seen no notice taken of the case you publish in your Clinical Notes of THE LANCET of Dec. 18th as to the need of caution in the administration of salicylic acid. The fatal result there mentioned, in my opinion and probably of others, was in no way due (unless the drug was impure) to the medicinal dose given (15 grs.) of that remedy. True, the symptoms did not appear to call for its administration, for there was *no fever* or history of malaria; and even if symptoms were due to latent rheumatism as was supposed, other remedies might have been preferable. It would be regrettable if, in the case published, the *post hoc* and not the *propter hoc* should cause needless fear and prevent the proper use of this very valuable medicine.

I am, Sirs, your obedient servant,

Jan. 15th, 1887. FREDK. H. ALDERSON, M.D.

DIPHTHERIA AND MILK.

To the Editors of THE LANCET.

SIRS,—The prevalence of diphtheria renders it incumbent on all who have opportunities of studying its causation or propagation to ventilate their views. I wish to offer a small but important contribution to the subject of propagation of diphtheria and other diseases by milk-supply, and also to make a suggestion with regard to preventive measures. It has frequently happened to me to see the household milk-can, supplied by the dairy, in the patient's room and in close proximity to him, and even used by him to drink from. Some residue of milk, in all probability highly infectious, is returned in the can to the dairy, where it may or may not (often, I fear, the latter), be subjected to the action of boiling water or steam. If, as must often happen, it is simply rinsed in hot water with many others, these are in turn infected, and will affect the milk supplied to various households. Medical men would be doing a great public service in the cause of disease prevention by giving orders in every household where infectious disease exists that no milk-cans be taken into such houses at all.

I am, Sirs, your obedient servant,

H. CAMPBELL POPE, M.D. Lond., F.R.C.S.

Goldhawk-road, W., Feb. 1887.

UNIVERSITY OF EDINBURGH.

To the Editors of THE LANCET.

SIRS,—With reference to your annotation in last week's issue, permit me to inform you that no "gross charges" were brought against my late assistant by me, nor were illegal charges of any kind intentionally made against him, even by imputation.—I am, Sirs, yours obediently,

Feb. 9th, 1887. W. RUTHERFORD.

THE SANATORIUM BUILDINGS OF KINGSTON-UPON-HULL.

To the Editors of THE LANCET.

SIRS,—In reference to your criticism upon the annual report of the health of the borough of Kingston-upon-Hull, which appeared in your issue of Jan. 1st, attention is directed to the new Sanatorium buildings, which are stated to be defective. The washhouse mentioned in your criticism is twenty-three feet from the road, and it is intended that all articles before being removed from the fever blocks will be disinfected by being placed in a solution of some reliable disinfectant and conveyed away in proper receptacles provided for the purpose, and its situation was so planned that persons engaged could in nowise be in communication with the hospital buildings. The wards for probationers are distant some thirty feet from the administrative department, being connected only by a covered way. The greatest care has been exercised in the construction of the building, and the plans have been submitted to various eminent authorities, also to Her Majesty's Local Government Board inspectors, during their sanitary surveys.

I am, Sirs, yours truly,

JOHN W. MASON,
Medical Officer of Health for the Town and Port of Kingston-upon-Hull.

Town Hall, Hull, Jan. 19th, 1887.

*** The publication of the above letter has been unavoidably delayed.—ED. L.

THE PRESENCE OF BLOOD IN THE PERITONEAL CAVITY.

To the Editors of THE LANCET.

SIRS,—I can unfortunately claim no credit for the conclusions as to the necessity for reconsidering the advisability of operation in cases of extravasation into the peritoneal cavity which Mr. Lawson Tait ascribes to me in your issue of last week, and to which, by implication, he raises such strong objections. These conclusions are not to be found in my thesis, but are those of the writer of the article referred to, who has viewed my experiments and observations chiefly in their bearing on this important practical question. On the question of the advisability or non-advisability of operation in such cases, I am not qualified, nor have I ventured, to speak. My experiments, so far as they bear on this question, deal almost exclusively with the fate of the extravasated blood—the conditions influencing its absorption, and the extent to which its red corpuscles are at once absorbed back into the circulation. Any conclusions, however, which have been arrived at will be found to differ very materially from those of Mr. Lawson Tait, when he allows himself to state, without bringing forward any facts to support his assertion, that the function of the peritoneum in man differs "most materially" from that of the peritonea in dogs and rabbits.

I am, Sirs, your obedient servant,

Edinburgh, Feb. 7th, 1887. WILLIAM HUNTER, M.D.

LIVERPOOL.

(From our own Correspondent.)

THE ASSIZES.

THE South-west Lancashire assizes, which are held in Liverpool four times a year, include all local and county cases within a certain radius. Occasionally cases which should have been tried in Manchester are tried here. The present assizes commenced on the 4th inst., before Mr. Justice Hawkins, and comprise a very large number of cases, some of a very serious character. One, which is known as the Oldham poisoning case, will for several reasons assume most of the characters of a *cause célèbre*. The prisoner, who was at the time of the occurrence a nurse in the workhouse at Oldham, is charged with having murdered her daughter, a girl eleven years of age, by administering a corrosive poison. One remarkable circumstance in connexion with the case is that though the prisoner has been committed on the coroner's warrant, the magistrates dismissed the case.

FATAL ACCIDENT TO A FIREMAN AND REMARKABLE ESCAPES.

Liverpool is justly proud of its fire brigade, and, considering the very dangerous character of their calling, it is remarkable how few fatal accidents occur either to the firemen or to the police officers who assist them. At a recent warehouse fire a wall fell down, killing a constable instantaneously, and injuring, though only slightly, a number of others. It was not known that the deceased constable was at the fire, he not having reported himself, but as he was missing search was made, and his remains were found in the ruins. The escape of all those firemen on whom the wall fell is little short of miraculous.

APPOINTMENT OF OCULIST TO THE ROYAL INFIRMARY.

It having been resolved by the Committee of the Royal Infirmary to create an additional medical officer as oculist, Mr. Thomas Bickerton has been selected as the first holder of the office. Mr. Bickerton, who is the son of a former oculist in this city, is known by his painstaking inquiries into the subject of colour-blindness.

SWING-BOAT FATALITY.

An inquest was recently held at Bootle on the body of a young woman who was thrown out of a swing-boat on the 5th inst., and died soon afterwards from the effects of the fall. The police sergeant stated that five accidents from swing-boats had occurred to his knowledge within the last three months, and he had heard of numerous others. The proprietor of the swing-boat admitted that they were allowed to go level high, and it appeared that half an hour after the accident the swings were going as high as before. A verdict of "Accidental death" was returned, and the proprietor of the swing-boat was severely censured for the manner in which he gave his evidence.

THE INFECTIOUS DISEASES HOSPITAL.

The Hospitals Committee of the Corporation are advertising the office of visiting physician to the Netherfield-road Hospital, at a salary of £100 per annum. The office, which is a newly created one under the Corporation, will be of great importance, and much interest is felt as to who will be first appointed.

Liverpool, Feb. 9th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE INFIRMARY.

THE annual meeting of the governors of the Newcastle Infirmary was held on Thursday, the 3rd inst., and in view of the proposed changes so strongly recommended by the Special Committee, and which were the subject of a previous letter from me, the meeting was looked forward to with considerable interest, especially by the medical staff and students, whom, as I have told you, the committee handled in rather an ungracious manner. The annual report showed that during the year 3175 in-patients had been admitted, being 329 more than during the previous year. The average stay of each patient in the hospital had been 29·6 days. In the four years immediately preceding it was 30·1, 31·2, 36, and 39, so that in this respect there has been a gradual improvement. The death-rate for the year had been 6·55 per cent. The average cost of each patient had been £3 17*s.* 11½*d.* This was much smaller than in some previous years. The cost of each occupied bed during the year had been £48 1*s.* 2*d.*; in 1885 it had been £50 16*s.* 6*d.* The number of out-patients received during the year had been 4641. The result of treatment of the in- and out-door patients during the year has been: in- and out-patients cured, 5490; relieved, 1697; in- and out-patients still under treatment, 421. The number of casuals that have been treated during the year is 19,624, against 27,811 in the previous year. The reason of this large diminution is that at the quarterly meeting of governors on July 8th it was resolved to charge casualty patients 3*d.* on each visit from Aug. 1st. The effect of this resolution is seen in the following figures:—From Jan. 1st to July 31st 14,178 patients were relieved, but from Aug. 1st to Dec. 31st only 5446 applied for relief. Of these, 4385 paid the amount charged, and 1061 were relieved without payment on account of their poverty. The report states that it is the opinion of the resident medical officers, to whom the care of casuals is committed, that after the charge of 3*d.* had been made a superior class of patients presented themselves, persons who would not accept of charitable assistance, but had no objection to be cured cheaply, while the very necessitous diminished in numbers. The resolution of the governors expressly provided for the destitute, but at present the report states "they appear to be scared away." The famished and ill-clad children of destitute or drunken parents, it is pointed out, are subject to a variety of diseases, for the relief of which they had hitherto resorted to the infirmary. These, the report states, are a class deserving of sympathy, and it says that the resolution imposing a charge of 3*d.* on each casual will be again taken into consideration after the plan has been in operation a year. The statistics as to the various classes of operations are interesting, but would take up too much space to record here. The report states, in speaking of the major operations, "that probably few hospitals, if any, could give so favourable a report of this serious class of operations," and that therefore "the situation of the Newcastle Infirmary cannot be so insanitary as it is supposed sometimes to be." The report then alludes to the grave pecuniary position of the infirmary. The whole expenditure of the year had amounted to £13,695, showing a diminished outlay, notwithstanding an increase of patients, of £252 10*s.*, but yet exceeding the ordinary income by £5325 6*s.* The report went on to say "we began the year with an overdraft due to the treasurer of £5403 4*s.* 4*d.* The whole of the ordinary income of the year has been used

Digitized by Google

up, together with £141 received in subscriptions for the completion of the Ravensworth ward, in addition to this £3000 consols, part of the capital of the institution, has been sold. Notwithstanding all this, the institution finds itself at the close of the year in debt to the treasurer in the sum of £2450 11*s.* 10*d.* To meet this deficit corporation bonds to the amount of £4000, also forming part of the capital, had been sold, still leaving a debt due to the treasurer of £2450 11*s.* 10*d.* A very animated discussion took place on the reading of the report, as also on the report of the Special Committee, but this last was referred to the Medical Board and two other committees, to report to a special meeting of governors to be held on the first Thursday of next March. It is apparent that the infirmary cannot go on in its present condition, and the whole drift of its affairs is in the direction of a free hospital, and the giving none of the responsibility of its support to the artisans of the district, who more directly benefit from it than any other class.

LEEDS BOROUGH HOSPITAL.

Leeds has been of late years remarkably free from epidemics of typhus, although in past times the resources of the Fever Hospital were frequently strained on this account. Within the past few months, however, there has been a serious amount of this disease, and about sixty cases have been received in the Borough Hospital. No less than seven of the nurses have been infected, fortunately with no fatal result, and the general mortality has not been high. The Borough Hospital, lately under the management of a committee as a public charity, has been acquired by the sanitary authority, and modernised from the old "corridor" type into a building more in accordance with modern requirements. Some further improvements, however, as to warming and ventilation, are, I believe, to be considered, at the suggestion of the medical advisers of the Local Government Board.

Newcastle-on-Tyne, Feb. 7th.

EDINBURGH.

(From our own Correspondent.)

PRESENTATION TO SIR DOUGLAS MACLAGAN.

On Monday afternoon a large assembly of ladies and gentlemen gathered in the Freemasons' Hall on the occasion of the presentation of his bust and portrait to Sir Douglas Maclagan by his friends and admirers. The platform, which was tastefully decorated with palms, was occupied by a number of leading men in the city and the University, amongst them the Lord Justice-General (Chancellor of the University), Lord Balfour of Burleigh, Lord Moncreiff, the Lord Provost of Edinburgh, Principal Sir W. Muir, Professors Crum Brown and T. R. Fraser, and many others. On the motion of Sir Alexander Christison, the Lord Justice-General (Lord Inglis) took the chair. Apologies for absence were intimated from Mr. Erichsen, Sir Joseph Fayrer, Sir Noel Paton, Lord Trayner, and others. To the right and left of the chair were the bust and picture of Sir Douglas Maclagan, both veiled; Sir Douglas himself and Miss Maclagan occupied seats to the right of the chair. Lord Inglis, in making the presentation, referred to his own early comradeship with Sir Douglas when they entered the High School together, and to the long years of close friendship that have followed. He did not venture to sum up his professional attainments and achievements in the presence of so many of Sir Douglas's professional compeers, but referred to some of the special honours which those merits have won him; making mention of the fact that Sir Douglas has held the office of President of both of the Royal Colleges, and of the honour recently received at the hands of Her Majesty the Queen in recognition of his varied public services. Lord Inglis then spoke of the veteran service rendered to the University by Sir Douglas during his tenure of the Chair of Medical Jurisprudence for nearly a quarter of a century, and of the great expansion that has taken place in the practical and theoretic instruction in public health under his personal supervision. Turning to the other side of his character, the speaker described Sir Douglas as "a man of highly cultivated mind, well versed in literature, both classical and modern, a poet, a sweet singer, an ardent sportsman, a loyal Volunteer, and a great officer in Her Majesty's body guard for Scotland." He has been, and is all this, just because his habits have been so active and sprightly, because he has such a happy and lovable disposition, without the slightest trace of cynicism or gall, and because of his inclination at all times to look on the best and brightest side both of men and things." The bust and the picture were then unveiled amidst great applause, and were formally presented by Lord Inglis. Sir Douglas Maclagan, in accepting the bust, spoke of the peculiarly delicate nature of the circumstances in which he found himself, and of the difficulty of expressing adequately his sense of the kindness showered upon him in so overwhelming a manner. Referring to the proverb of the empty vessel making the loudest sound, he attributed any incompleteness of his utterance to his being replete with gratitude. On behalf of himself and Miss Maclagan, for whom the portrait was destined, Sir Douglas accepted also the remarkably faithful likeness painted by Mr. George Reid, R.S.A., to whose talent, as to that of Mr. Hutchison, the sculptor, he paid a warm tribute. Votes of thanks were accorded to these gentlemen for the admirable way in which they had carried out the wishes of those concerned in the presentation; also to Dr. Gibson, the treasurer, and Mr. Lyell and Dr. Ashdown, the secretaries, whose efforts have so efficiently realised the object in view. A similar compliment to the chairman terminated the proceedings.

THE STUDENTS' UNION.

The final adjustment of the accounts of the recent monster bazaar shows that between £10,000 and £11,000 are available for the purposes of erecting the University Union. A site in close proximity to the new medical buildings has been selected, and plans of the proposed edifice are now in course of preparation.

THE LORD RECTORSHIP.

The Lord Rectorship, vacant through the lamented death of Lord Iddesleigh, presents a question of some difficulty. It is thought very undesirable that another contested election should be fought out so soon after the last struggle. A proposal that his Royal Highness the Prince of Wales should be requested to fill the office has been very graciously negatived on his behalf. It is hoped, however, that a candidate may still be forthcoming in regard to whom there will be no clashing of party sentiment, and whose unanimous election may be secured.

ASYLUM APPOINTMENT.

The Colonial Secretary has appointed Mr. J. B. Spence, M.A., M.B., assistant-physician at the Royal Edinburgh Asylum, to be Medical Superintendent of the Ceylon Asylum.

Edinburgh, Feb. 8th.

DUBLIN.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE question of the College forming dual combinations with the College of Physicians and the Apothecaries' Hall of Ireland was under discussion at a meeting of the Council of this College last week. Although there is no doubt that the combination would be a legal one, yet under present circumstances it has been thought advisable not to move in the matter; but there is a strong probability of a dual scheme being formed at no distant date. The College (see *ante*, page 102) have resolved to constitute a diploma in public health, and have matured a scheme of examination. Details will shortly be published, but it may be mentioned that all candidates who possess a registrable qualification will be eligible for the diploma. The Council have adopted a vote of condolence with the family of the late Mr. Denham, an ex-president of the College.

DUBLIN SANITARY ASSOCIATION.

The annual meeting was held last week, the inaugural address being given by the President, Dr. Grimshaw. He showed that Dublin alone of all the great towns of the United Kingdom had an increased death-rate, after having for ten years enjoyed in common with other cities the advantages of improved sanitary laws and the opportunities for improved administration. From the annual report of the Association it would appear to be doing good work, but the results of its operations, it must be confessed, are not very

Digitized by Google

tangible. It will surprise many to learn that for the ten years ending 1884 about 3500 more lives were lost than in the previous decade, while in other cities the gain has been relatively greater than our loss. It must not, however, be forgotten, as Dr. Grimshaw points out, that it takes a long time for sanitary measures to make a marked impression on a previously delicate population, and a still longer time to produce a permanent improvement.

THE LATE G. E. BRUNKER, M.D., F.R.C.S.I.

At the advanced age of eighty-three years, Mr. Brunker died at his residence near Dublin, on the 2nd inst. He graduated in medicine at Edinburgh in 1826, and obtained the Fellowship of the Royal College of Surgeons in Ireland in 1844. He held the post of surgeon to the Louth County Infirmary for a considerable period, and on his retirement from practice settled in Dublin. He took a very active part in getting an alteration made in the Charter of the College of Surgeons, so as to allow provincial and other Fellows to vote for the election of President, Vice-President, and Council by voting papers. A resolution was proposed by Mr. Brunker to this effect in June, 1883, and was adopted at a meeting of the Fellows. He was for a short time a member of the Council of the College.

SIR P. DUN'S HOSPITAL.

At a special meeting of the governors, held recently, a cheque for £1000 was received, being the amount of a legacy left by a Mrs. Hughes to the hospital. The executors requested that the money should be expended towards the construction of separate wards for the treatment of fever patients, in accordance with the wish of the deceased lady. The amount has been lodged to the credit of the Fever Wing Fund. The available funds, in consequence of the difficulty of obtaining rents from the estate of the hospital, have been seriously diminished, and the governors during the past six years have been obliged to sell out stock to the amount of £3500, to meet the expenses of the institution.

HEALTH OF DUBLIN.

The deaths from zymotic diseases during the past quarter numbered 318, being 14 above those recorded for the previous quarter. Over 32 per cent. of the mortality from zymotic affections was due to scarlatina, which caused 103 deaths, or 60 in excess of the preceding three months. Six deaths were attributed to cerebro-spinal fever, a disease which may be said to have existed as an epidemic in Dublin for the past eighteen months.

THE LATE DR. O'CONNELL.

The remains of the late Dr. O'Connell of Kilmallock were interred in the family burial-ground at Ballingaddy on Saturday, the 29th ult. The deceased served as a surgeon in the British army, and took part in various engagements in Spain in 1830 to 1835. For his services he was presented with a gold medal of the Legion of Honour by Queen Isabella, and the honour of knighthood was conferred upon him (Knight of the Order of St. Ferdinand) for attending the Queen in her accouchement.

FOOTBALL.

One of the players at the International Football Match (Ireland *v.* England), which was held on Saturday last in Dublin, received a severe injury to the head, and is now suffering from concussion of the brain.

Sir George H. Porter, surgeon to the Queen in Ireland, was last week sworn in as High Sheriff of co. Wexford, in the Court of Exchequer, before the Lord Chief Baron.

Dublin, Feb. 8th.

THE SUBSOIL OF LONDON STREETS.—The Chairman of the Board of Works, Sir J. M'Garel-Hogg, M.P., has introduced a Bill for conferring further powers on the Board with respect to the subsoil of streets and the laying of mains or pipes. It proposes that without the consent of the vestry or the district board no road is to be made over land where the sand, gravel, or subsoil has been taken away. And without this consent none of this subsoil under a road already made is to be removed. In cases where this consent is given, any conditions may be imposed. But in such cases and in case of the consent being refused, an appeal is permitted to the Board itself. Similar restrictions as to obtaining the approval of the vestry or board as to depth, position, and course are imposed by the Bill with respect to laying mains or pipes under any new street.

PARIS.

(From our own Correspondent.)

THE HEALTH OF PARIS.

HITHERTO the supply of putrid Seine water in the place of that of the Vanne has not had any appreciable effect upon the mortality. Indeed, the number of deaths from typhoid recorded in the last *Bulletin de Statistique Municipale* was much smaller than usual. It is a matter, however, of common observation that typhoid has increased in frequency, and in the Montparnasse quarter more particularly bowel complaints of an unusual kind are exceedingly prevalent. According to Dr. Roussel, who is well known in England in connexion with transfusion, there is an epidemic of hæmorrhagic convulsive enteritis in this district. Whilst passing along the street a few days since he saw a child fall down in a fit and void blood. A summary inquiry elicited the fact that attacks of this kind were quite common amongst the children of the poorer classes, and further investigation showed that they only occurred in the families of those who are supplied with offensively-smelling water. I may mention, as one instance out of many, that several *employés* of a large administration are now absent on account of bowel troubles, and those who are not actually ill are suffering from intestinal irritation.

PASTEURIANA.

With the exception of the appearance of the first number of the "Annales de l'Institut Pasteur," the past week has been comparatively uneventful. The official delegate of the Portuguese Government has, it is true, made known, in a letter to the *Gazette des Hôpitaux*, his impressions upon the subject, but they are too vague to amount to an opinion. Unless I am mistaken, the writer has not yet made up his mind as to the value of the method; although he is inspired with respectful veneration for M. Pasteur himself. In my last letter the name of the physician who made the post-mortem examination in the case of Bergé was written "Peter." To M. Peter I referred a few lines further on, but the Dean of the Faculty of Bordeaux mentioned in the preceding paragraph is M. Pitres, an eminent pathologist, and one whose opinion upon the case in question will be authoritative.

CHLORAL ERUPTION.

Dr. Barbillion contributes a paper to the *Archives de Physiologie* upon a variety of erythema appearing in patients under the influence of chloral, upon the administration of alcohol. The chloral eruption was first recognised by Jastrowitz in 1869, and has since been met with by numerous observers. The point to which Dr. Barbillion calls attention is the almost mathematical regularity with which the exanthem appears under certain circumstances. Given a child of from four to eight years of age, who is taking from two to four grammes of chloral daily in repeated small doses, the administration of alcohol in the form of wine or spirit mixture will cause the appearance of the rash in from fifteen to thirty minutes.

ALCOHOLISM.

That the best remedy for alcoholism lies in the restriction of the use of alcohol seems almost a foregone conclusion. But in the present condition of public exchequers there are few ministers of finance who would venture to adopt such a measure, and hence intemperance in the use of spirituous liquors is almost universally tolerated, if not encouraged, in the interest of the revenue. And yet it is admitted in France that 40 per cent. of the cases of mental alienation, and one-half of the murders committed, to say nothing of minor consequences in disease and crime, are due to alcohol. This great question of intemperance, its causes and results, has been the subject of a number of independent studies lately by economists, humanitarians, and scientific men, and there is a growing opinion that the evil is not wholly incurable, and that there is even a possibility of dealing with it to the satisfaction of all legitimate interests. Alcoholism does not necessarily result from the abuse of alcohol. At the recent discussion on the adulteration of wine at the Academy of Medicine the speakers were agreed on this point. Excess in the use of alcoholic drinks of good quality causes simple inebriation, which has its train of morbid symptoms, but these are quite different from those

Digitized by Google

of alcoholism. The classical drunkard, merry and expansive in his cups, the true "knight of the burning lamp," common enough in Burgundy, where the good wine is evidently kept for home consumption, is seldom met with in Paris. The *ouvrier*, who drinks in the capital, is pale and wasted, and when excited becomes aggressive. If his existence is not cut prematurely short by accident or disease—and under the former heading must be included suicide and the scaffold,—it generally ends in the hospital or the asylum, and his children, if there are any, have the same prospect for their sole inheritance. Notwithstanding the increasing prevalence of diseases due to alcoholism, it is stated by M. Aglade, who delivered a lecture on the subject a few days ago at the Sorbonne, that drunkenness is not on the increase. It is the toxic property of the alcohol consumed that has become greater, and the remedy exists in the prevention of adulteration. Formerly intoxication was induced with ethylic alcohol distilled from wine, but at the present day, of 1,872,000 hectolitres of alcohol consumed annually in France, scarcely 25,000 are extracted from wine. The remainder is derived from potato, beetroot, rice, maize, &c. Some of these so-called "higher" alcohols are extremely dangerous ones. Amylic alcohol, for instance, is seven times more toxic than the ethylic, 1·1 gramme per kilogramme of body-weight being a fatal dose. The statements of the lecturer were illustrated by experiments upon dogs and guinea-pigs, which were watched by the public with interest, and not disturbed by any hostile manifestations. A small quantity of ethylic alcohol being injected under the skin of a guinea-pig, the animal became lively, but was not otherwise disturbed. The same quantity of amylic alcohol administered in the same way to another guinea-pig was followed by paralysis of the legs, and it died, as if stunned, in a few minutes. The experiment being repeated upon dogs, gave similar results. With ethylic alcohol there was merely increased liveliness; with amylic alcohol, stupor and inertia. But when absinthe was used, the injection of less than a cubic centimetre caused death in a fit of furious delirium. The remedy for alcoholism proposed by M. Aglade is the supply of unadulterated alcohol, which should be a State monopoly, and this would not only reduce the evils of drink to a minimum, but, according to M. Aglade, the revenue would gain more than £40,000,000 a year.

MEDICAL NOTES IN PARLIAMENT.

The Lunacy Laws.

IN the House of Lords, on the 7th inst., the Lord Chancellor moved the second reading of the Lunacy Bill. He stated that with the exception of one controversial matter the measure was substantially the same as that which on two previous occasions had been agreed to in that House. He believed that no alteration of the law would be satisfactory if it did not make further provision for the liberty of the subject. The Bill made it a condition of the power of restraint that upon every person alleged to be a lunatic there should be served a notice, giving him information that if he pleased he could be taken before a magistrate.—Lord Herschell, in supporting the second reading, said he sympathised with the desire of his noble and learned friend to safeguard the liberty of the subject as much as possible, so far as it could be done with safety to the lunatic.—The Earl of Milltown hoped their lordships would take steps to prevent an abuse of the Lunacy Laws, and to increase the visiting power of the Lunacy Commissioners.—The Bill was read a second time.

The Lord Chancellor then moved the second reading of the Lunacy Bill, the object of which, he explained, was to codify the Acts of Parliament, numbering something like 30, dealing with the subject of lunacy.—The Bill was read a second time.

The discussion of the Lunacy Acts Amendment Bill in Committee in the House of Lords has been fixed for the 21st inst., instead of the 15th inst., the date to which the Committee was originally postponed.

The Military Colleges.

In the House of Commons on the 3rd inst., in reply to Sir H. Tyler, Mr. Stanhope stated that, as regards the Royal Military Academy, the provision of increased sleeping accommodation and of hot water for the bath-rooms will be proceeded with when funds are available after the completion of more urgent services. No room in Herbert's Hospital can at present be made available as an infectious ward for cadets. As regards Sandhurst, steps have been taken to carry out the recommendations that the riding school be lit with gas, that better furniture be provided for the cadets' ante-rooms, that windows be added in certain rooms, and that a dressing-room be added to the gymnasium; but funds are not as yet available for building accommodation for the servants on the college estate.

Mad Dogs and Hydrophobia.

On the 8th inst., Lord John Manners, in reply to Mr. H. S. Wright, stated that the enforcing of the regulations respecting the muzzling of dogs lay in the hands of the local authorities, and that the Government did not intend to take further steps in the matter of regulations.

In reply to Mr. Coghill, who asked whether the Government intend taking any steps to found an institution in London similar to M. Pasteur's in Paris for the gratuitous treatment of persons who have been bitten by mad dogs, Mr. Ritchie said that the report of the committee now investigating the Pasteur system would, when presented, receive careful consideration.

Dover Barracks.

Mr. Stanhope, in reply to Mr. Norris, said that since the death of Lieutenant Jarrett, in December last, a thorough inspection had been made of Dover Barracks, but no insanitary conditions had been discovered. Every precaution against an outbreak of typhoid fever had been adopted. The medical officer of the district was responsible for the sanitary condition of the barracks.

The Condition of the Thames.

Mr. Bigwood gave notice of his intention on an early day to move the appointment of a Select Committee to inquire into and report on the state of the River Thames in the neighbourhood of Richmond, Twickenham, and Brentford, and to consider what remedies might be applied.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the above College, held on Thursday, the 10th inst., the following motion was passed:—"That, as recommended by the Court of Examiners, it be referred to the Committee of Management to consider and report to the two Colleges on the advisability of extending the rule by which, under the old regulations, candidates obtaining fourteen out of the fifteen marks required to pass the examination in Surgery are admissible to re-examination after a period of three, instead of six, months' additional study, to those candidates examined in Surgery under the regulations of the Examining Board in England by the Royal College of Physicians of London, and the Royal College of Surgeons of England."

The report of the committee on the extension of the College premises was received, approved, and adopted. The report included the following recommendations:—

"1. That the College premises be extended in the manner proposed in the first report; but that the alterations thereby occasioned be carried out gradually, and be subject to such modificatious in matters of detail as the Council, on the recommendation of the Committee, may hereafter approve. 2. And that the Committee be authorised to make arrangements for the erection, with as little delay as possible, of an additional Museum, as shown in the plans, on the ground occupied by the back premises of Nos. 43 and 44, Lincoln's-inn-fields, abutting on Portugal-street, and for the construction of an additional storey to the main building of the College to accommodate the new work-rooms, at an approximate cost of £10,000 for the new museum, and £5000 for the new work-rooms."

To carry out Sir T. Spencer Wells' resolution the Council elected a committee, consisting of Sir James Paget, Sir T. Spencer Wells, and Mr. John Marshall, with the President and Vice-President, to confer with a deputation from the Association of Fellows and from the Association of Members on the subject of the first resolution, passed at the meeting of Fellows and Members on Nov. 4th of last year.

Mr. H. G. Howse was elected a member of the Court of

Digitized by Google

Examiners in Surgery, in the vacancy caused by the resignation of Professor Humphry.

A communication was read from the Registrar of the Royal College of Physicians, informing the Council of the appointment of a deputation consisting of the President, Treasurer, and Registrar, to confer on the question how the two Colleges may duly celebrate conjointly the Jubilee Year of Her Majesty's reign. The Council appointed the President and two Vice-Presidents to meet these delegates.

Another communication was read from the Registrar of the Royal College of Physicians, inviting the College to associate itself with the former College in granting the diploma in public health. The invitation was accepted by the Council, and it was referred to the Committee of Management to devise a scheme for carrying out the necessary arrangements for the purpose, and report them to the two Colleges.

A communication was read from Mr. Handfield Jones, forwarding the resolutions passed at the St. Mary's Medical Society concerning the title of Doctor.

Obituary.

FRANCESCO MAGNI.

THE greatest Italian ophthalmologist since Vacca died at San Remo on the 2nd inst.

Francesco Magni was born at Spedaletto, in the Province of Pistoia, Tuscany, in July, 1828. Having completed his secondary curriculum in the Pistoiese Liceo Forteguerri, he devoted himself to the study of medicine in the University of Pisa, where he won the respect of his teachers and the affection of his fellow-students by his sedulous application and his genial vivacity. Like most of the generous Italian youth of his time, the upheaval of 1848-49 drew him into the vortex of the revolution, and he abandoned the bedside and the laboratory to assist in the patriotic campaign. He was no less ardent and effective as a soldier than as a student, and, in particular, at the stubborn fight of Curtatone, where he was wounded, he earned the honourable mention of his commanding officer. The war over, he proceeded to Florence, and at the Hospital of Santa Maria Nuova he steadily and rapidly made up the arrears of study and observation incurred by his service in the field. From Florence he started on a professional tour, and visited in succession, each time for a considerable period, the principal cliniques of Germany, France, and England. Ophthalmic surgery was his favourite branch of medicine, and the opportunities he enjoyed, particularly under von Graefe, were not thrown away upon him. On his return to Florence, where he graduated, he filled the post of director of the Anatomical School until 1859, and in the following year he was transferred to Bologna to occupy the chair of Oftalmoiatria, and to conduct the clinique attached to it. Having acquired a sound and solid reputation in the ophthalmic specialty, he proceeded to America, and in the chief cities of the northern States he enhanced his already distinguished name for the centripetal exactness of his diagnoses and the brilliant success of his operations. Fortune as well as fame attended him in his subsequent career, his increasing lucrative clientèle necessitating periodical visits to the chief cities of the Italian peninsula. With all this occupation he found time to enrich the literature of his subject with contributions to the leading medical journals, in which the student will find it worth while to refer to the following papers:—"Lezioni di Oftalmoiatria" (*Rivista Clinica*, 1861-67); "Sarcoma sulla Cornea" (*Ebdomadario Clinico*, 1861); "Lezioni teoriche di Oftalmoiatria" (Bologna, 1867); "Descrizione della Cassula di Tenone" (1868); Contribuzione alla Anatomia Patologica dello Strabismo" (1868); "Sopra alcune Anomalie di forma nella Lente dell' Occhio umano" (1868); "Contribuzione allo Studio del Glaucoma" (1871); "Sugli Effetti del Processo flogistico della Coroide" (1872) "Il Processo flogistico considerato in alcuni Tessuti dell' Organo visivo" (1877); and an able treatise on University Reform addressed to Coppino, Minister of Public Instruction (1878).

Besides being an effective clinical prelector and brilliant operator, Dr. Magni took an energetic part in politics. He was elevated to the dignity of Senator of the Kingdom in 1876, and proved of the greatest service to successive Ministries, particularly in the field of public health and State medicine. He was a consistent but independent adherent of the Italian Left, and (what in Italy means devotion to the same school of politics) an ardent Freemason. His death, which was sudden, was due to asystole, of which he had lately had many premonitory symptoms.

VINCENT AMBLER, F.F.P.S.G.

THIS gentleman, who for many years past has been known as a West-end London practitioner, died suddenly in his bed on Sunday last, Feb. 6th, at his residence, No. 14, Colville-square. He commenced his medical career in the Crimea during the war, being then a student of medicine, and received the Order of Medjidie, 2nd class, as well as English and Turkish war medals. He qualified for medicine in 1866, and became F.F.P.S., L.S.A., and L.M. He had considerable practice amongst some of the foreign legations resident in London, was appointed Physician in Ordinary to the Japanese Legation and to the Persian Embassy, and was decorated with the G.K.C. of the Ancient Order of Lion and Sun, conferred on him by the Shah of Persia. A man of artistic tastes and accomplishments, of energetic nature, and of kind, hospitable disposition, he enjoyed the society of a wide circle of friends and acquaintances. His fatal illness commenced between two and three years ago, and was marked by severe attacks of spasmodic apnœa, for which he consulted Dr. B. W. Richardson, who diagnosed thoracic aneurysm, and who obtained a sphygmographic aneurysmal tracing at a pulsating point to the right of the sternum on the level of the nipple. Quite aware of his danger, Mr. Ambler nevertheless persisted in following out his professional work, and for many months past seemed to improve, the pulsation having ceased, and being succeeded by dulness and other signs of filling of the aneurysmal sac by fibrinous deposition. He remained at work, attending regularly to his duties, public and private, until Jan. 21st, when there was a return of the spasmodic apnœa, which passed away under rest and suitable remedies. He recommenced work in two or three days, did a fair amount on Saturday, and awoke on Sunday morning in his usual state, partook of a light breakfast in bed, and, lying down again to sleep, expired while still sleeping. His remains were interred in Kensal Green Cemetery on Wednesday last.

Medical News.

BRITISH AND INDIAN MEDICAL SERVICES.—The following Surgeons on probation in the Medical Departments of the British and Indian Armies were successful at both the London and Netley examinations held on Feb. 7th. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the lists which follow:—

THE annual ball in aid of the funds of the Newark Hospital took place on the 3rd inst.

THE death of Mr. Arthur Woolnough of Carlisle, from an overdose of chloral, occurred on the 31st ult.

THE twenty-seventh annual dinner of the old students of King's College was held on the 4th instant.

DONATION.—A. W. Shaw, J.P., has given £50 to Barrington's Hospital, Limerick.

H.R.H. THE DUKE OF CAMBRIDGE will preside at a public dinner on April 19th in aid of the funds of the Ventnor Consumption Hospital.

A DEATH from hydrophobia occurred on the 4th inst. in the Nottingham General Hospital. Muzzling regulations for dogs are in force in Nottingham.

LORD WOLVERTON has contributed £1000 to Morley House (Hospital Saturday Convalescent Home) upon condition that a four-bedded room, to be called the "Wolverton Room," shall be set apart for London postmen.

THE second annual general meeting in connexion with the Newbury District Hospital was held on Jan. 25th, when satisfactory financial and medical reports were presented.

GUY'S HOSPITAL.—A sum of £5730 has been collected among the members of the Stock Exchange in aid of Guy's Hospital, and has been sent towards the special fund of the hospital started at the Mansion House.

AT the annual meeting of the subscribers to the Ashburton and Buckfastleigh Cottage Hospital, on Jan. 28th, it was resolved that the work of erecting a new building be proceeded with forthwith.

AT the recent annual meeting of the collectors and subscribers of the Metropolitan Hospital Saturday Fund, it was reported that the committee had divided among the participating institutions £9750, or £250 more than in any former year.

PRESENTATION.—Mr. Isidore Prager, on his resignation of the post of house-surgeon to the National Dental Hospital, has recently been presented with a silver hot-water apparatus for surgery use by the staff and students of that institution.

AT a farm at Chignal, Essex, thirty-nine animals have, within the past few days, died of anthrax, and seventeen have been slaughtered; in all, fifty-nine out of sixty-two head of cattle have been lost. Every precaution has been taken to prevent the spread of the disease.

MEDICAL MAGISTRATES.—Edward England Phillips, L.R.C.P.E., M.R.C.S., L.S.A., medical officer of health to the Southend Urban and Rochford Rural Sanitary Authorities, and George Davidson Deeping, L.R.C.P. Lond., M.R.C.S., L.S.A., have been placed on the Commission of the Peace for the county of Essex.

ROYAL UNITED HOSPITAL, BATH.—The annual meeting of the supporters of this institution was held on the 24th ult. The report, which was read by the secretary, showed the receipts for the past year to have been £5676, an increase of £1328 as compared with 1885; while the legacies showed a decrease of £218, being only £649. The expenditure, amounting to £6026, exhibited an increase of £449.

THE fourth annual dinner of the members of the Association of Public Sanitary Inspectors was held on the 5th inst., Mr. Edwin Chadwick, C.B., the president of the Association, occupying the chair.

A PRIZE of fifty thousand francs is offered by the French Minister of Education for a discovery rendering electricity economically applicable in the shape of heat, light, chemical action, mechanical power, transmission of messages, or treatment of disease. A committee, with M. Bertrand, of the Academy of Sciences, as chairman, will adjudicate.

BRADFORD CHILDREN'S HOSPITAL.—At the annual general meeting of subscribers to this institution on the 28th ult., the secretary reported that the receipts amounted during the year to £552, and the expenditure to £526. The fund which was raised for the extension of the hospital amounts to over £4600, and the committee are in search of a building suitable for the purpose.

ROYAL UNIVERSITY OF IRELAND.—At a recent meeting of the Senate, the following additional Examiners in the Faculty of Medicine for 1887 were appointed:—Medicine: Stephen M'Swiney. Midwifery: John A. Byrne and H. M. Jones. Medical Jurisprudence: E. W. Davy and M. M'Hugh. Materia Medica: F. J. Quinlan and J. S. Reid.

HOSPITALS ASSOCIATION.—At the third general meeting of this Association, to be held at the Outer Temple (Room 44), 225, Strand, on Wednesday, Feb. 16th, at 8 P.M., a paper will be read by Miss E. G. Mansion, entitled "Is it desirable for Metropolitan Hospitals to possess Nursing Institutions, and to supply Nurses for Private Cases outside the Hospital walls?"

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The library of the College will be closed on Saturday, Monday, and Tuesday, the 12th, 14th, and 15th inst. for the purposes of the Hunterian Oration and Festival.—Professor W. H. H. Jessop, F.R.C.S., will deliver a course of three lectures on "The Intra-ocular Muscles," on Wednesday, Friday, and Monday, February 16th, 18th, and 21st, at 4 P.M. precisely each day.

SERIOUS EPIDEMIC OF MEASLES.—News has been received in Paris of an outbreak of a peculiarly virulent form of measles among the inhabitants of Saint Pierre and Miquelon, a couple of islands about ninety square miles in extent, situated off the Newfoundland coast. One thousand children out of a total population of 5700 are affected, and several deaths occur daily, either from the immediate effects of the disease or from secondary complications.

DURHAM COUNTY HOSPITAL.—The annual meeting of the governors and subscribers to this institution was held on the 1st inst., when it was reported that during the past year there had been 419 in- and 1513 out-patients, a decrease of 52 in-patients and an increase of 270 out-patients as compared with the preceding year. The income for the year was £2286, and the expenditure amounted to £3590, the latter amount including a balance of £1229 brought forward from the year before.

ROYAL FREE HOSPITAL.—The fifty-ninth annual meeting of the governors of this institution was held on the 3rd inst., under the presidency of Mr. James Hopgood. The receipts from all sources have, the secretary reported, amounted to £20,063, and the total ordinary expenditure to £11,121, as compared with £11,085 in 1885. The number of in-patients admitted was 1813, the daily average in the wards being 138, as against 125 in 1885. The number of out-patients who received advice and medicine was 22,191.

MEDICAL ATTENDANCE ORGANISATION COMMITTEE.—At the fourth meeting of the above committee on Feb. 8th, Sir T. Spencer Wells in the chair, the following resolution was passed: "That local committees are recommended to obtain from applicants for membership a declaration that, in the case of a single person or man and wife, their average earnings do not exceed 30*s.* per week; or of a family, 40*s.* per week; or of domestic servants, £15 per annum: those whose earnings are over this amount being, as a rule, ineligible for membership." The next meeting of the committee will be held on the 22nd inst., when they will proceed to consider the rates of contribution and benefits.

Digitized by Google

CITY OF LONDON TRUSS SOCIETY.—Under the presidency of Mr. J. Norbury, the seventy-ninth annual meeting of the governors of this charity, the object of which is indicated by its name, was held on the 2nd inst. From the annual report, which was read and adopted, it appears that the gross income during the past year amounted to £4189, as against £4062 in 1885. The total expenditure was £4926. During 1886, 9394 patients of all ages and both sexes were relieved, being the largest number ever relieved in one year since the foundation of the charity. The total number relieved to the end of last December since 1807 amounts to 422,710 patients. The number of instruments supplied during the year was 9436. Permission was afterwards obtained to sell out the funded property of the charity to the amount of £1250, in order to pay off a loan and to meet its growing requirements.

THE JUBILEE.—At a meeting of the Blackpool Town Council on the 1st inst., it was resolved that a public hospital and dispensary should be erected in commemoration of Her Majesty's Jubilee. A sum of £9000 is, it is stated, already available for endowment purposes.—On the 3rd inst., at Folkestone, it was decided to erect a large hospital in celebration of the same event, and several large contributions have been promised.—At a public meeting at Mexborough, on the 1st inst., it was resolved that a Jubilee Cottage Hospital be erected in the town.—The inhabitants of Skipton, Yorkshire, have decided to celebrate the Queen's Jubilee by erecting a Hospital for Infectious Diseases, at a cost of £3000.—In view of the Queen's Jubilee a commemorative dinner of the friends and supporters of the Dental Hospital of London will be held at the Hotel Métropole on Thursday, March 10th, under the presidency of Sir James Paget, Bart., F.R.S.—At the annual meeting of the friends and supporters of the Queen's Hospital, Birmingham, on the 7th inst., it was resolved that an effort be made to raise a Jubilee fund of £10,000, one half to be spent in improving the building, and the other half to be kept in hand so as to avoid financial embarrassments in the future.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BRIGGS, HENRY, M.B., C.M.Ed., F.R.C.S.E., has been reappointed Honorary Medical Officer to the Hospital for Women, Shaw-street, Liverpool.

BRODIE, F. CARDEW, M.R.C.S., L.R.C.P., L.S.A., has been appointed House-Physician to the Middlesex Hospital.

BURTON, JOHN EARP, L.R.C.P.Lond., M.R.C.S., has been reappointed Surgeon to the Hospital for Women, Shaw-street, Liverpool.

CARTER, T. H., M.B.Lond., M.R.C.S., has been appointed Surgeon to the Stamford and Rutland Infirmary.

CHAMPNEYS, FRANCIS HENRY, M.A., M.B.Oxon., F.R.C.P.Lond., has been appointed Consulting Physician to the General Lying-in Hospital, York-road, Lambeth.

COSGRAVE, E MACDOWEL, M.D., M.K.Q.C.P.I., has been appointed Physician to the Heytesbury Industrial School, Dublin, vice Walter Smith, M.D., resigned.

EDIS, J. BUTLER, L.R.C.P. Ed., M.R.C.S., has been reappointed Honorary Assistant Medical Officer to the Hospital for Women, Shaw-street, Liverpool.

JORDAN, FURNEAUX, F.R.C.S.E., has been appointed Consulting Surgeon to the Queen's Hospital, Birmingham.

PHILLIPS, EDWARD ENGLAND, L.R.C.P.Ed., M.R.C.S., L.S.A., has been re-elected Medical Officer of Health for the Southend-on-Sea Urban Sanitary Authority, Essex.

POLLARD, REGINALD, M.B.Dur., M.R.C.S., has been elected Physician to the Western Hospital, Torquay, vice Nankivill, resigned.

RAMSAY, R. HAMILTON, M.D., C.M.Glas., has been elected Physician to the Western Hospital, Torquay, vice Hounsell, deceased.

ROBERTS, THOMAS A., L.D.S., has been appointed Honorary Dental Surgeon to the Pimlico-road Free Dispensary, vice G. W. Payne, L.D.S., retired.

SHORT, THOMAS SYDNEY, M.B., M.R.C.S., L.S.A. Cert. San. Sci. Camb., has been appointed Resident Medical Officer to the Jaffray Hospital, near Birmingham.

SPENCE, J. B., M.A., M.B., Assistant-Physician, Royal Edinburgh Asylum, has been appointed Medical Superintendent of the Ceylon Asylum.

STEELE, CHARLES E., M.R.C.S., L.S.A., has been reappointed Honorary Assistant Surgeon to the Hospital for Women, Shaw-street, Liverpool.

STEWART, JAMES, L.F.P. & S.Glas., &c., has been appointed Poor-law Medical Officer for the District of Rotherham, and also Public Vaccinator, vice D'Oyley Foote, M.D., M.R.C.S., L.M., deceased.

WHARRY, H. G. O., M.R.C.S., L.S.A., has been elected House-Surgeon and Secretary to the Scarborough Hospital and Dispensary, vice Kenneth Frazer, B.A., M.D. Dub. Univ.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM GENERAL HOSPITAL.—Two Assistant House-Surgeons. No salary, but residence, board and washing, will be provided.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, London, S.W.—Three Clinical Assistants. Salary £5 5s. for a period of three months.

GLAMORGANSHIRE AND MONMOUTH INFIRMARY AND DISPENSARY, Cardiff.—Ophthalmic Surgeon.

PRESTON AND COUNTY OF LANCASTER ROYAL INFIRMARY.—Senior House-Surgeon. Salary £100 per annum, with lodging, washing, and board.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London.—Junior House-Physician. Salary £25 for six months, with board and lodging.

ST. ASAPH UNION.—Medical Officer. Salary £83 per annum.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—Honorary Visiting Physician.

WEST HERTS INFIRMARY, Hemel Hempstead.—House-Surgeon and Dispenser, to also act as Assistant-Secretary. Salary £100 per annum, with board, furnished rooms, fire, lights, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

COWARD.—On the 29th ult., at Burdett-road, Limehouse, the wife of Christopher T. Coward, L.F.P.S.Glas., L.S.A., of a daughter.

CROSSFIELD.—On the 1st inst., at Broadstone House, Dartmouth, the wife of A. Kyffin Crossfield, L.R.C.P.Ed., L.R.C.S., of a son.

SHERWOOD.—On the 2nd inst., at Eastbourne, the wife of Arthur P. Sherwood, L.R.C.P., of twins (daughter and son).

SKINNER.—On the 16th ult., at Dagshai, Punjab, the wife of Surgeon Bruce M. Skinner, L.R.C.P.Ed., M.R.C.S., Army Medical Staff, of a son.

SMITH.—On the 6th inst., at Kensington-gardens-square, the wife of E. Stanley Smith, L.R.C.P.Ed., M.R.C.S., of a daughter.

WYLIE.—On the 30th ult., at Dyneley House, Skipton, the wife of William Wylie, M.D., of a son.

MARRIAGES.

CAUDLE—BARTON.—On the 3rd inst., at St. John's Church, Calcutta, Charles E. Caudle, M.D., to Agnes, second daughter of the late Rev. R. G. Barton, late Rector of Etchingham, and of Urmston, Eastbourne.

DOUTY—CAZALET.—On the 29th ult., at the Parish Church, Leigh, near Worcester, by the Right Rev. the Lord Bishop of Worcester, uncle of the bride, assisted by the Rev. B. H. Sheppard, Rector, and by the Rev. W. G. Cazalet, brother of the bride, J. Harrington Douty, M.R.C.S.Eng., &c., Medical Superintendent (elect) of the Berks County Asylum, Moulsford, to Madeline, only daughter of Major G. H. Cazalet, of Bransford Court, Worcestershire, late of the 1st Royal Surrey Militia.

DOYLE—STEELE.—On the 3rd inst., at St. Luke's Chapel, Norwich Cathedral, Charles William Doyle, M.B., to Emma, daughter of the late Adam Rivers Steele, Barrister-at-law.

HALFORD—HOSE.—On the 2nd inst., at the Parish Church, Ealing, Edward Halford, M.D., to Latitia Thomasine, third daughter of the late Rev. Fredk. Hose, M.A., Rector of Dunstable, Beds.

O'CONNOR—RICHARDSON.—On the 5th inst., at the Parish Church, Chatteris, Cambs., Martin O'Connor, L.K.Q.C.P.I., L.R.C.S.I., to Julia Temperance, only surviving daughter of the late Fryer Richardson, Esq., of Fortrey House, Chatteris.

ROWLEY—FORDE.—On Dec. 21st, 1886, at St. Peter's-in-the-Forest, Bombay Settlement, Great South-road, Auckland, New Zealand, by the Rev. E. J. Macfarland, B.A., Charles Rowley, M.R.C.S.Eng., of Bombay, eldest son of Charles Octavius Rowley, M.R.C.S.Eng., of Barnsley, to Lilian Louisa, second daughter of the late Frederick Forde, J.P., of Bombay Settlement.

DEATHS.

FOOTE.—On the 3rd inst., at Croft's House, Rotherham, Yorks, Harry D'Oyley Foote, M.D., M.R.C.S.E., L.M., in the fifty-third year of his age. Friends will please accept this the only intimation.

GASKOIN.—On the 5th inst., at The Priory, Caerleon, Mon., George Gaskoin, M.R.C.S., late of Westbourne-park, London, aged 70.

HOWARD.—On the 6th inst., at New Buckenham, Norfolk (of diphtheria); Herbert Howard, M.R.C.S., L.R.C.P.Lond., in his 26th year.

MATHESON.—On the 5th inst., at his residence, Granville-place, Portman-square, Duncan Matheson, L.R.C.P.Ed., L.F.P.S.Glas.

SMITH.—On the 27th ult., at Portland House, Cheltenham, Thomas Smith, M.D., M.R.C.P.L., aged 74.

UNDERHILL.—On the 1st inst., Emily Margaretta, the beloved wife of William Lees Underhill, Surgeon, of Tipton.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, February 14.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Mr. W. Y. Dent: Building Materials (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Leopold Servais of Antwerp will read a report on Two cases of Enormous Tumours of the Face, treated by Removal of both Superior Maxillæ.

Tuesday, February 15.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department. Mondays and Thursdays, 9.30 A.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Respiration.
SOCIETY OF ARTS.—8 P.M. Mr. Allan Ransome: Some of Our Colonial Woods.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Hale White: On the falling out of Teeth in Tabes Dorsalis.—Mr. D'Arcy Power: Intermuscular Synovial Cysts.—Dr. Hyla Greves: Endothelioma of Dura Mater.—Dr. Semon (for Dr. Jacob): Syphilitic Hyperplastic Laryngitis.—Dr. Hadden: Mitral Aneurysm in a Child.—Mr. Shattock: Ectopia Vesicæ.—Mr. Clutton: Retro-pharyngeal Abscess.—Mr. Gould: Horny Growth on Penis.—Mr. Godlee: Adeno-sarcoma of Tongue with Calcifying Nodule in Centre. Card Specimens:—Dr. Hadden: Perforation of Large Intestine in Enteric Fever.—Mr. Fenwick: Renal Carcinoma.—Dr. Mott: Myxo-fibroma compressing the Spinal Cord.—Mr. Clutton: Congenital Abnormality of Lower Lip with Cleft Palate.

Wednesday, February 16.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
SOCIETY OF ARTS.—8 P.M. Mr. Henry H. Cunynghame: Uses, Objects, and Methods of Technical Education in Elementary Schools.

Thursday, February 17.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. A. W. Rücker: Molecular Forces.
PARKES MUSEUM OF HYGIENE.—5 P.M. Mr. Charles E. Cassal: Food Adulteration and Analysis.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. Sedgwick: Notes on the Collapse of Cholera.—Dr. Sidney Phillips: Some points in the Treatment of Fever.—Dr. A. H. N. Lewers: The best means of Dilating the Cervix Uteri.

Friday, February 18.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Mr. C. B. Paget: A Practical Illustration of the Protective Influence of Vaccination.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Mr. William Crookes: Genesis of Elements.

Saturday, February 19.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Carl Armbruster: Modern Composers of Classical Song—Jensen, Lassen, Holstein, Berlioz, and Wagner (with Vocal Illustrations).

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

SHOULD MEDICAL AID FRIENDLY SOCIETIES NOT BE SUPERVISED BY THE MEDICAL COUNCIL?

Philalethes, in a letter too long for insertion, draws a terrible picture of the evils likely to result if no legal check is put to the tendency of friendly societies to combine and exact heavy and responsible duties from medical men on grievously low terms. He thinks the Medical Council might supervise such societies in regard to their medical affairs, and see that they select proper officers and pay them properly. We lament with him the evils of the existing system, and we urge all medical men to decline those appointments; but we are of opinion that the profession must in this matter protect itself. The Legislature is too helpless just now, even if it had the wish, to do any such useful work as regulating the medical service of the friendly societies.

Ambulance.—Probably Furley's horse ambulance carriage would be found suitable. Our correspondent would do well to communicate with Mr. Furley on the subject.

Mr. Shelswell.—The paper is marked for early insertion.

WARMING OF RAILWAY CARRIAGES.

To the Editors of THE LANCET.

SIRS,—On reading last week's issue of THE LANCET I noticed an article on the above important subject, both as regards the health and comfort of railway passengers. It may not be known to very many, if to any, of the readers of THE LANCET that an apparatus for the warming of railway carriages has been invented and patented by Mr. Foulis, the engineer to the Glasgow Corporation Gasworks, and that experiments have taken place with it on the Glasgow and South-Western Railway which have proved it to be a great success. The following is an account of the apparatus which I have taken from the *Railway Review* of Jan. 21st.

"The heat is obtained from the gas-lamp in the roof of the carriage. At the top of each lamp there is a small water-heater, and from this the hot water descends by means of two small pipes about a quarter of an inch in diameter, encased in the panelling of each compartment. The pipes pass into heaters placed beneath the seats in the carriage, and these are so arranged that the air entering at the bottom of the heater, where it is coldest, passes up and leaves the heater at the top, where it is hottest, discharging a constant glow of hot air into the carriage. The heaters have fan-shaped mouths, so that there is no intermittency in the supply. Only one carraige has been fitted with the apparatus, but this has proved successful beyond anticipation. If this apparatus becomes general, railway passengers will have to thank Mr. Foulis for one of the greatest boons conferred upon them." I am, Sirs, yours truly,

Wednesbury, Feb. 8th, 1887. HENRY E. BLACKWOOD.

DRUNKENNESS IN BELGIUM

ACCORDING to statistics, Belgium is the most drunken country in Europe Where in 1850 there were 53,000 public-houses, there are now 195,000—that is to say, one for every 44 of the population. The Government is, however, taking steps to repress and prevent drunkenness. Should the Bills be carried, publicans who supply drink to persons obviously drunk, or to anyone under sixteen years of age, will be liable to a fine not exceeding £1 for the first offence, while if they cause a minor to drink to intoxication they may be fined £4. Whoever is responsible for serious illness resulting from intoxication may be fined from £2 to £80, with from a week to two years' imprisonment, according to the gravity of the case. Should death ensue, a fine varying from £10 to £200, and from five to ten years' imprisonment, may be imposed. Public-house debts are no longer to be recoverable.

Mr. Wm. Luks.—We have no knowledge of the "remedy" or of the person who advertises it.

K. K. might write to the bankers of the Fund, Messrs. Coutts, Strand.

SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—Having had occasion last week to escort a patient to the Continent, I had two rough journeys across the Channel to encounter. Most of my fellow-passengers paid a tribute to the power of Father Neptune. I escaped by a method which I should like to discuss, if you think it worth your space, which is so valuable.

I take it that all are agreed that in some way the nervous system is the primary cause of sea-sickness. I have heard it argued that this distressing malady is the consequence of variations in the pressure at different parts of the cerebro-spinal fluid, consequent on the varying position of the ship. My own notion is that a sort of vacuum is created in the abdominal cavity. Suppose, for instance, the ship is descending into the trough of a sea, the lower limbs feel the effect of the descent before the upper. The contents of the abdominal cavity are likewise drawn downwards, the uppermost contents being the last to feel the effect. Suppose at the same moment an expiration takes place, the diaphragm is at its highest. Under ordinary circumstances the viscera would be steadily pressed by the abdominal muscles, but in this case the diaphragm rises at the moment that the intestines tend to fall. The result is a momentary removal of pressure from the solar plexus and splanchnic nerves, followed by an unusual pressure. The result must be excessive action, followed by complete arrest of action. All rhythm must be lost before long under such circumstances. The result must be, it seems to me, that wild, inhibitory messages are sent to the heart, amongst other organs, resulting in the pallor which precedes each access of sickness. The directions to the various organs are equally excessive or equally wanting. At one moment saliva, bile, and other secretions are set flowing with extraordinary vigour; at the next arrested. The peristaltic action of the intestines becomes confused, and at times reversed, and the bile finds its way into the stomach. The action of the diaphragm becomes spasmodic, and sickness ensues. Assuming this theory to be correct, how does it throw light on the treatment? The method I adopted was this: Whenever the cockleshell in which I was travelling gave an extra roll I held my breath and contracted my abdominal muscles as much as I could. In this way I kept up a steady pressure on my solar plexus. When the boat travelled comparatively steadily for a moment or two, I breathed again. If for a moment I was off my guard and relaxed my abdominal muscles, that moment I felt that singular sinking sensation at the pit of the stomach which heralds *mal de mer*. Of course, this method is only applicable to short trips, such as that across the Channel. If the methods in vogue for treating sea-sickness be considered, it will be seen that many of them are explicable on my theory. When I was a ship's surgeon the plans most recommended by travellers were to administer bottled stout or champagne. In either case the gas evolved distends the stomach, and so keeps the pressure uniform. Another plan I have heard recommended is to eat pickled onions freely before going on board. Probably, in that case, too, indigestion produces evolution of gas, and so steady pressure. Could not an elastic belt be tried to help to keep up even pressure?

I am, Sirs, your obedient servant,

Southborough, February, 1887. E. PAGET THURSTAN, M.D.

"OBSTINATE CONSTIPATION IN AN INFANT."

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent, "O. P. Q.," who sought in your issue of Jan. 29th suggestions on the treatment of the above, I would advise him to eschew the administration of purgative medicines and enemata. He should try massage—gentle kneading of the abdomen, and friction over the region and in the direction of the colon, by which means muscular action is stimulated and the desired result produced. The process should be repeated once or twice, at fixed times, daily, until regular action of the bowels results. Of course, the diet has to be attended to, and the feeding regulated as to time and quantity. The child should be given passive exercise in the fresh air daily. Other readers might also, I venture to hope, try, and pronounce their opinions upon, this plan of treating obstinate constipation.

I am, Sirs, yours very truly,

Ramsgate, Feb. 3rd, 1887. JOHN LUCAS, M.D.

PROVIDENT DISPENSARIES SUICIDAL TO THE PROFESSION.

To the Editors of THE LANCET.

SIRS,—Your correspondent, Dr. Dickinson, not long ago stated that the Wandsworth Medical Aid Society—and I take this one simply as a type of all the others—provides medicines and medical attendance, either at the patient's house or the doctor's surgery, for 5000 people for one year for £350. In my district they do the same. Besides, a host of letters are given away, so that almost anyone can attend a local hospital for nothing. Again, the London hospitals are within a cheap ride. And I quite agree with your correspondent that it is usual for half a dozen of the oldest practitioners in the district to allow their names to be placed on such a list. They really ought to be ashamed of it. Why do they do this? Because they want to keep all the patients on their own books; and they would attend the whole lot for nothing rather than let them go to a fresh man. These old practitioners have secured the best class of patients, and to prevent opposition they will attend the ragged lot for next to nothing. Under the cloak of charity it is a lever to try to starve a new man and give vent to their professional jealousy. How is a doctor to start a practice, and who are likely to be his first patients? These are the very people upon whom he depends; yet they are to be gathered into the old practitioner's net, and treated for an ignominious fee to prevent any other doctor having them on better terms. The people who pay these pence regularly are those who can very well afford to pay a shilling or two each time the doctor attends them. The other class will not subscribe. Then, the sole gives less than 4*s.* a year for each patient. Now, if a patient but went to the doctor, say, for a couple of bottles of physic, he would pay that amount. If it be necessary to have this sort of charity, let the public bear the burden of it, and not medical men. For every member who pays 4*s.* let the public add 6*s.*, so as to offer something like a fee to which a doctor is entitled. On what grounds is a doctor always to be a tool of charity? The poverty of the profession flourishes on the jealous suicidal policy of its members. They endeavour to grasp each other's patients by offering skill at a lower fee. Even then, not content, they play the *rôle* of cat's paw to the parson's monkey. Who gets the chestnuts? The public. Who gets the honour? The parson. Who does the work? The doctor. What other professional man works seven days and two nights a week? What other professional man has so poor an income and such ill-proportioned expenses? At this rate a doctor's income should be double a lawyer's. But it is not. There is talk of increasing the student's period of study by a year or so. What is he to have afterwards? The dignity attached to attending and supplying patients with physic for 4*s.* a year. Happy man! Your correspondents are usually well-to-do men, of position and ability, and who have sufficient from practice or otherwise to keep them. Therefore you rarely hear from my class, and rarely hear how the beneficent system takes the butter from the struggling doctor's bread. There is very little *esprit de corps* in general practice, and we wage a war of extermination against each other with kid gloves on. Those who support and encourage these clubs and charitable associations are working against the mass of doctors for the good of a few. As you undoubtedly support all forms of charity, I trust you will bestow a little of it, by inserting this in your journal, on

Yours faithfully,

Dec. 13th, 1886. A GRUMBLER.

S. P. J.—General Maxwell's treatise, entitled "The Beaufort Artificial Arms and Legs for the Crippled Poor," is printed for private distribution, and will be freely sent to all applicants who are interested in the charity. Requests for copies should be addressed to General H. H. Maxwell, C.B., R.A., Villa Gamberini, Via Palestro, Rome.

Enquirer.—The best inhaler for the administration of the A.C.E. mixture is the perforated leather cone, containing a sponge and lined with flannel. Several layers of lint may be used, and even Junker's apparatus in operations of the face and mouth.

U. V. is referred to announcements in our advertising columns.

AN IMPROVED TRICYCLE.

To the Editors of THE LANCET.

SIRS,—May I call your attention to a tricycle which I saw at the Stanley Show last Saturday, and which seems to me to be a great improvement on the ordinary kind of machine. Certainly it is so from a medical point of view. We have all noticed how the ordinary tricycle—and, for the matter of that, the bicycle as well—tends to round the shoulders and contract the chest. In the machine to which I wish to call your attention this evil is entirely removed. The action which propels this machine is precisely that of rowing. The rider sits upright, and literally rows himself along, and that at a first-rate speed. Instead of only a few groups of muscles being brought into play, all the muscles of the body are, as in rowing, at work. The advantages of the sliding seat are obtained by means of a moving stretcher, this movement itself aiding in the propulsion of the machine. Dr. Richardson has often written about the advantages of tricycle exercise. I wish he would try this new machine, as I feel sure he would endorse my views. The machine has been invented by Mr. J. Inglis Mitchell, C.E., and is being exhibited by Mr. A. Doman. It is called the "Jubilee" tricycle.

I remain, Sirs, yours faithfully,

Holloway-road, N., Feb. 1st, 1887. W. HENRY KRETZEMER.

THE VACANCY AT ST. BARTHOLOMEW'S.

THE name of Dr. W. E. Steavenson was placed amongst the list of candidates for the post of assistant-physician to this hospital in our last issue. This was a mistake, as Dr. Steavenson is in charge of the electrical department, and did not apply for the appointment.

Dr. R. W. Foss.—The paper was published in the tenth report of the Medical Officer of the Privy Council. We do not know whether this volume is out of print.

Mr. C. S. Jeaffreson.—As early as possible.

"THE GENERAL MEDICAL COUNCIL AND UNQUALIFIED ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—Your correspondent, "Unqualified Assistant," asks, in your last issue, if "scores of hard-working and valuable unqualified assistants are to go to the workhouse" because the General Medical Council is proposing to abolish their further use, and mentions their "long and faithful" services to the profession, and concludes by suggesting that a special Register should be made for their peculiar benefit. This is simply the wildest nonsense that could be penned in support of an abuse that ought never to have been allowed. No such unqualified man can engage in practice without palming himself off as a "doctor," and as such he is, in plain words, deceiving the public, with the sanction of the greater offender, who knowingly employs him. Would the public receive an unqualified man if he went to them in his true colour? Certainly not. And why should they? The law has a test which the public generally expect medical men to comply with. So long as this abuse is tolerated by the General Medical Council it will only put a premium upon ignorance, and encourage the idle and lazy among *chronic students* who have neither the brains nor the perseverance to work for a qualification to become what is erroneously called an "unqualified assistant." It is not fair or just to the young qualified man, who has after hard work reached the required standard and gained his legal status, to be check mated by a hybrid who is neither student nor qualified. At the present time, as matters stand, a man may graduate in the best university and become duly registered, and the only return he gets from the Medical Council is simply a copy of the Register containing his name and degree, &c., with no protection whatever against any poacher, no matter how unqualified he may be. There are in the kingdom very many entrances into the medical profession, and the highest standard required in the best of them is not too severe for an ordinary student who shows a desire to obtain the distinction. Ordinary men have obtained these distinctions, and can still obtain them if they only try in the proper way.

I am, Sirs, yours faithfully,

Feb. 7th, 1887. NUDA VERITAS.

An Old Assistant, in a communication on the above subject, writes:—"There are men on the Medical Register who have no diplomas and possess no legal qualification, but are registered for service. On the Medical Register for 1884 are about twenty such men. They are registered for services variously obtained—the army, navy, public service, and as surgeons, under the 46th Section of the Medical Act, 1858. If the 46th Section admitted these unqualified men on the Medical Register, why not make the same use of that Section and admit all old assistants of approved education and antecedents, and allow them to act as assistants, or, if possible, if their private means allow, to gradually improve their positions and become legally qualified? I am an old assistant myself, am now running on fast to the age of threescore years, have liked my vocation, and could have legally qualified nearly thirty years since; but forty years and more have gone since I became a probationer, previously to apprenticeship under the Act of 1815. In due time I completed my apprenticeship, and gained in the seven years and a half an insight into practice which has stood me in good stead. I was then a fair all-round practitioner. I tried to gain employment, but was told that if I 'legally qualified' I must 'be gone.' I was left a parentless youth with only a small patrimony. Still, I am a man of full curriculum, and of a university to boot. I considered, and made a resolution, upon which I have acted for forty years, that it was better to be a rich assistant than a poor principal; and in my case it has paid. I only held two assistancies in thirty-six years, was employed in first-class situations, loved my work and all its surroundings, obtained good salaries, worked hard, and merited my masters' approbation, keeping my bonds never to injure my masters or their families by proceeding to qualify and register. Such has succeeded well with me. In my sere time of life a place on the Register will avail nothing. I have lived a life free from disputes and tergiversation; but I have been spared the bitterness of non-success. I am in comfortable circumstances. My masters are both dead. I have stood a guardian's part to the last master's widow and family. I married at thirty years of age, or a little under that age, and have brought up a family of three daughters and one son. My son is a university undergraduate, who will soon obtain his degrees in medicine and surgery. The experience I have gained has been of great value in knowing how to handle the reins. I have given my children good education, and do not regret in one particle the plan I have followed. Had I my time over again I should follow out the same plan. I am fully aware that a man cannot do now as a medical assistant what was done twenty, thirty, or forty years ago. A more advanced curriculum is demanded, and an extended compulsory classical and mathematical examination is required. But are the medicos of the present day better men? I think not. If all circumstances are fairly balanced, I think the same standard of perfection would have been reached. The Medical Council ought to take a fair percentage of those who matriculate, and take an estimate of causes of failure to pass the finals, and in all fit and proper cases allow a man to work as an assistant under a legally qualified practitioner, or, if experienced and above a certain age, to be registered under the 46th Section of August 1st, 1858."

DROWSINESS ACCOMPANYING DYSPEPSIA.

To the Editors of THE LANCET.

SIRS,—I shall feel obliged if some of your numerous correspondents will give me their views as to the actual cause of the extreme drowsiness and torpor that one meets with in some cases of dyspepsia. Is it due to anæmia, or congestion of the brain, or to some poisonous product in the blood, the result of mal-assimilation? I am not speaking of that lesser degree of drowsiness which most people experience after a heavy meal, but a state of what one may call almost constant sleep, not confined to gross eaters or to those who lead sedentary lives. Some of these people will sleep all day, even after breakfast the desire for sleep being almost irresistible. Treatment in the way of drugs seems to be of little avail. Any information on the subject, as well as any treatment that has been found successful, will be very acceptable.

I am, Sirs, yours faithfully,

Jan. 29th, 1887. L.R.C.P. LOND., M.R.C.S.

Asclepiad.—The latest contribution to the literature of malaria in its nature and its etiology is the paper read at the Roman Academy of Medicine on Jan. 23rd, 1887, and published in the Transactions of that body.

Mr. H. Sergeant.—The alterations in the matriculation to which we referred were adopted at a meeting of the Senate on Dec. 22nd, 1886, but we cannot say how soon they will be embodied in the official regulations, or take effect.

Circocele.—All forms of medical treatment aim at securing obliteration of the affected veins, and we know of none which succeed without this.

Mr. H. Fenwick.—Yes.

G. P.—The question has been repeatedly answered.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Bland Sutton, London; Dr. Cullingworth, Manchester; Mr. M. Handfield Jones, London; Dr. C. The Hunterian Oration

DELIVERED AT THE

ROYAL COLLEGE OF SURGEONS OF ENGLAND,

Monday, February 14th, 1887,

BY WILLIAM S. SAVORY, F.R.S.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—No word of defence can be needful for the form in which English surgeons have chosen to celebrate the memory of Hunter; but an apology may be offered by one who now attempts the task of speaking of him. The duty of reviewing in this place the life and work of Hunter has been so often and so ably performed that it seems to me I can do but little else than incur failure by any effort to tread in such familiar footsteps. But although tempted, as I may have been, by this and other reasons to turn aside into some less known path, yet a natural sense of loyalty to the great surgeon and of responsibility to the trust I have accepted has constrained me, and so Hunter in his work must be again the subject of what is called with oppressive grandeur the "Hunterian Oration."

Surgeons with one voice have proclaimed the supremacy of Hunter above all who have ever studied surgery. Students of science have acknowledged him to be among the chief of those who have in any age advanced human knowledge. Yet although his claims have been often examined, and many students and surgeons have been engaged in the task, his greatest to the high place he holds is not always recognised, perhaps not even always understood. May I stand excused, then, for asking once more, and attempting to answer the question, What has Hunter done?

It has been well said that when we attempt to estimate the achievements of the foremost men of past ages too often we see them only in eclipse. A large part—it may be much the larger part—of what they did is too often hidden from us. The proportion of sudden, or what may now appear as sudden, discoveries may be seen, though from afar; they may still strike us even from a distance. But we can now no longer adequately appreciate the conditions under which the pioneers of knowledge laboured. In the light of the present day it is difficult to realise the darkness of past times, or to measure fairly the part they played in dispelling it. We may diligently trace the course they took, and become familiar with every step of it, and yet fail to understand that they not only trod, but actually made the way.

But was Hunter a great discoverer—I mean in the ordinary sense of the word? For we speak of discoveries in science, sometimes forgetting that all real progress involves discovery. What are the particular discoveries, then, or improvements in the art of surgery, which are now recalled by the mention of his name? We quote at once, as an instance, the operation for aneurysm, known to all as the Hunterian, and then—we pause. What else shall be declared upon which his fame particularly rests? Anyone, indeed, who has but a passing acquaintance with the works of Hunter can speedily furnish a long list of important papers in which many new and valuable facts are revealed, and knowledge largely increased, not only in anatomy and physiology, but in pathology and surgery. More than one or two of these would alone suffice to establish the author's claim to ability and industry of no common order; but in none of them can be pointed out, I think, any particular discovery in surgery from the loss of which Hunter's fame as a surgeon would materially suffer.

But let us go further. As a surgeon was Hunter pre-eminently skilful in practice? Was he, beyond all other surgeons of his time, sagacious in diagnosis or successful in treatment? Was he even dexterous in operation? I do not know where to find the evidence upon which these questions can be answered in the affirmative; indeed, on the latter point there is evidence to the contrary. Or, once more, was he a learned man in his profession, as the phrase is commonly understood? Was he, as we say, a "well-read" man? Was he fully informed of the labours of others? I fear it must be admitted that the testimony in favour of this belief is very slender too. The introduction of the operation for aneurysm which bears his name was indeed a great step onward. In taking it he gave ample proof of rare foresight, which could proceed only from sound apprehension of some important facts in pathology and surgery, and a masterly grasp of some of the leading truths of physiology. Yet we bear witness to Hunter's fame when we acknowledge that even this grand discovery, among the chief in surgery, adds comparatively little to it.

What more, then, did Hunter achieve? What was he, therefore? Wherein consists his greatness? He was, and is, beyond and above all surgeons, a philosopher in surgery. His idea of the subject of his thoughts was far more adequate than that of other men. He was supreme in the scope and method of his work. He understood much better than those around him how to engage in the interpretation of Nature; he knew best how to approach and to disclose truth; for he not only understood that the problems which lay immediately before him were of all the most complex and difficult to solve, but he could see also that they were not isolated, but dependent ones. He saw in the necessary relation in which they stood to others the only means by which they could be worked out, and on this understanding he resolved to investigate the questions he desired to answer. But consider for a moment what, with the light in which Hunter then stood, that resolution involved. Remember how often, in more recent times, have able men doubted the doctrine, hesitated to accept the idea of that intimate relationship between the various forms of life—of their continuity, of that harmony of plan, of that unity of design, which Hunter not only clearly conceived, but so accepted as a vital truth that he made it the foundation of all his labours; and, after all, the only sure test of genuine and thorough belief is the work which comes out of it. This was the principle on which Hunter never wavered; it was the star that guided him—without haste, without rest—through all the work of his life.

But observe, I pray you, further, how Hunter proceeded in his work, for this is eminently characteristic of the man. He is not fond of starting propositions, which are then supported by arguments and made plain by illustrations; but his practice is to demonstrate in their order, without comment or dissertation, the facts which reveal knowledge. His habit appears to be, not to say to us, "I am convinced of this, and I will tell you why there can be no doubt about it," but rather to place the premisses before us—sometimes, it may be, with indifference, certainly without regard to effect, or any attempt at direction. His purpose appears to have been uniformly not to support a conclusion, but rather to make way for one. This, I think, is inscribed on the proudest monument of his genius—his Museum. May I ask you, only for a few moments, to look once more at it?

The passion of Hunter for collecting is well known; it has often been the subject of comment. His Museum included not only, to use the words of Professor Flower, "illustrations of life in all its aspects, in health and in disease; specimens of botany, zoology, palæontology, anatomy, physiology, and every branch of pathology; preparations made according to all the methods then known; stuffed birds, mammals and reptiles, fossils, dried shells, corals, insects, and plants; bones and articulated skeletons; injected, dried and varnished vascular preparations; dried preparations of hollow viscera; mercurial injections, dried and in spirit; vermilion injections; dissected preparations in spirit of both vegetable and animal structures, natural and morbid; undissected animals in spirit, showing external form or waiting leisure for examination; calculi and various animal concretions; even a collection of microscopic objects: but it extended to minerals, coins, pictures, ancient coats of mail, weapons of various dates and nations, and other so-called 'articles of vertu.'" Yet I do not doubt that, notwithstanding the apparently miscellaneous character of a great part of his museum, this vast collection was very far from being what could be called an empirical one. Save in material, it had nothing in common, as some would suggest, with an old curiosity shop. For myself, I believe that even the objects found there, which appear most foreign to the

Digitized by Google

subject of his thoughts and work, were not introduced from mere idle fancy, but for the purpose, either at once clearly or dimly seen, or, if otherwise, at least conceived possible, of throwing light in some way upon the great questions of which his mind was full. I submit that this view is worthier than the prevailing one of the character of Hunter; and it is fortified by evidence of the strongest kind. Look at that section of his Museum which, as Professor Flower truly says, is most characteristic of the man—that which is called, and I venture still to think well called, the physiological. Had it been somewhat more fragmentary than it was when he left it, had not a fuller light been thrown on the truth it illustrates by the masterly labours of von Baer, the brilliant exposition of Milne Edwards, and the thoughtful volumes of Carpenter, how much longer would the great idea, that governs this unrivalled series, have remained concealed? Nay, even still, how often in the comments made on it, is this idea unheeded or overlooked? It is a magnificent collection of comparative anatomy, or, as we may speak now, of morphology. It sets forth the variations in form which the different organs undergo in different species, or in the same species under different conditions. But, above all, it introduces us, in the happiest way, to the study of comparative physiology. It demonstrates the great law of progress from the general to the special; the law of evolution from the simple to the complex; the principle of elaboration, and advancement of function by division of labour. Or, again, as Professor Flower admirably puts it—and need I apologise for quoting him here in reference to the Museum?—it throws "light upon one of the great biological problems, classification; which, when rightly interpreted, means nothing more or less than a statement of the order in which living beings have been evolved from one another." I know not, indeed, whether Hunter ever formulated this idea. He has not laid down the law in explicit terms. I can find no distinct expression of it in any sentence he has written which has reached us. But, then, hasty generalisation was no habit of his mind. I do not doubt that, in some large degree, he grasped it, and had he lived on, as the truth became established, he would have made it plain to all. When his labour ceased, he was working out the great idea. But by such glimpses as we thus obtain of the character of his mind and the method of his inquiry, of the way of his genius to begin the search for the truths he sought at the furthest outposts, and thence, so to speak, to work inward and upward, I cannot regard the possession of any facts or illustrations which he was enabled to collect, but had not time to place, as wanton or purposeless, or even merely curious. To me they are wonderful, but withal most suggestive, that the great mind of Hunter was not only far in advance of his own age, but is hardly overtaken by this.

The same method of work is plain in Hunter's labours in surgery. He was ever searching for principles, but strove to reach them only through facts. Facts always first; but never facts only. From facts to principles. He understood that all progress mainly depends on the power of grouping and uniting for some new purpose facts that have been discovered independently, and that are daily being revealed, yet with little or no reference to the principles they are found to support. And here, again, after a careful examination of Hunter's work in surgery, it is necessary to pause and review it in relation to the knowledge of his time. Then I think we are impressed, not so much by the actual advance he made in the art, as by the degree in which, through the character of his work, he raised surgery to the level of a science. I would almost venture to say that he effected more by the nature of the questions which he set than by the answers which he worked out. Surely his conception of surgery, of its possibilities in the future, of its relation to the sciences, of the plan—the only sure one—upon which it could be advanced, went very far beyond that of any surgeon before him—shall I say has gone far beyond that of most surgeons after him? But if he could thus estimate the task before him, what shall we say or think of Hunter as we watch him, with unexampled diligence and patience, pondering over the preface? Never turning a page of the great book of Nature, which he had set himself to read, until each sentence before him had been duly weighed, and all that he could learn from it had been secured. But this was not enough. He not only saw that surgery, to be soundly established, must rest upon pathology, but that the language of pathology required an interpreter; that its problems could be solved only by the light of physiology. Where in any work before his—nay, where in any since—shall we find such a union of physiology and surgery? In the pages of Hunter, but there I think only, are they found, as they should be, literally woven into one. We study his chapters on the Blood, on Inflammation, and on Gunshot Wounds, and acknowledge that nowhere else are the principles of pathology so supported and illustrated by the facts and truths of physiology. Yes, as no one before him has given proof of so clear and ample a conception of the relation of surgery to natural science, so in no one since has it borne such fruit. Hunter not only saw more fully than anyone who preceded him the way in which the art of surgery, through a knowledge of physiology, could be advanced, but he possessed the happy power of working to far better purpose upon this understanding than any of his successors. Nay more, the same power of mind which gave him a larger grasp of surgery raised him to a loftier view of the science on which it is founded. He knew better than other men in what direction to look, and when he turned his eyes thither he could see further.

So now, as we stand upon higher ground on this side of it, we can discern, I think, the idea which pervaded Hunter's work. He saw that surgery in his time was but a rude empirical art, consisting of little else than a knowledge of many facts which stood in no visible relation to each other, and of many more opinions which, for the most part, had no relation, or but a very distant one, to any facts whatever; that surgery should be raised from a collection of such creeds to the rank of a science; but this could be only by founding its practice upon sound principles. The discovery of some at least of these principles was Hunter's final aim. But these principles could not be reached by guessing; they could be approached only through the orderly investigation of facts. But then an explanation of these facts themselves could be only through the truths of physiology. The signs of disease could be understood only by him who had studied the laws of life and health. An intelligent interpretation of the one could only be in proportion to a previous knowledge of the other. But the problems of life and health are presented to us in man in their most complex form—in a form so difficult that even Hunter could not solve it. They must be reduced to simpler terms through a study of the lower forms of life. Thus, with the ultimate aim of relieving human suffering, Hunter studied the phenomena of motion in plants. Nay, he went further—to crystals and other forms of inorganic matter,—and he says: "The better to understand animal matter, it is necessary to understand the properties of common matter, in order to see how far these properties are introduced into the vegetable and animal operations." Note the characteristic thought at the end of the sentence. He does not start with a denial or an assumption, but he is anxious to "see how far." And if it must be said that in his attempt to grapple with the crucial problem of life Hunter failed, it must be acknowledged that he failed only in the task where none have hitherto succeeded. And the weakness he exhibits here appears chiefly in the fact that he encountered this, the greatest of all questions before him, not always according to his wont, by careful, patient, and impartial investigation of the facts which lead up to it; but it must be confessed that the dominant idea of a living or vital principle was too ready to do duty for causes that were to him then, as they are to us now, obscure. Yet, even here where Hunter is tried by the severest of all tests, one cannot but observe in what favourable contrast he stands to others who have attempted to solve the problem; how determined he is, for instance, to depend for the most part on experiment, and how comparatively trivial has been the advance in actual knowledge of the subject since his time. Recently we have learnt, indeed, to recognise more fully the play in the living body of the common forces or forms of force of nature; and hence we have been led to suppose that the forces peculiarly vital may hold the same relation to them as they do to each other; that all the distinctive phenomena of vital action may depend on the transformation of force with which elsewhere we have become in effect more or less familiar. But beyond this attempt to see, as Hunter put it, how far the common forces of nature are concerned in the phenomena of life, and the reasonable conjecture that has hence arisen of the relation of the vital within us, and the forces around us, how much further have we gone? Yes, Hunter stood before the crowning mystery of life, and could not raise the veil. But, then, to whom

Digitized by Google

amongst the sons of men has it been yet given to draw it aside? Let the darkness which, after another century of thought and work, still enshrouds the subject be the comment on Hunter's reflections on the nature of life.

Now, perhaps the question may be worth asking, How far is it practicable in the present day to turn to good account the priceless legacy which Hunter has left us in the record of the plan on which he studied surgery? How far is it possible to follow now, at however great a distance, the example which he set? Or to put it thus:—Supposing Hunter to have lived in our day, could the range of his work have been still as ample? How much of what he did depended for its scope on himself?—how much on the scanty state of knowledge of his time? If Hunter lived amongst us now, his grasp of natural science and of surgery would, of course, be very different from what it was in the last century. It is common to remark that knowledge in this, as in other directions, has increased so largely that the relation in which any man can stand to the whole of it must be very different now from what it was a hundred years ago.

As knowledge advances, and the sum of it accumulates, the share which any one man can appropriate must of necessity gradually grow less, and become a smaller fraction of the whole. There can be no help for this or remedy, save in a corresponding advance in the development of the human mind. What reflection is more familiar to us than that on the progress of knowledge? But is the power of apprehending it greater now than it was in the days of Plato or Aristotle? This must mean that, as the world goes on, the attainments of even the foremost in intellectual power must become more partial. Who now would dare to talk of taking all knowledge for his province? It involves the fact of greater individual incompleteness. In the old days, the best men could be more on a level with the knowledge of their time. Thence every year onward places even these further below it, and the great law of division of labour prevails. Yet for this there is a gracious law of compensation. For while, on the one hand, there is now so much more to be seen; on the other, the master minds of previous ages have made it much easier for us to see. For by the establishment of principles, the outcome of their labours, we are raised, as it were, upon the shoulders of our ancestors, and the horizon of our vision is more comprehensive than theirs. For as facts accumulate and principles become moulded out of them, not only does the apprehension of these principles enable us, except for special purposes, to dispense with many facts, but such expansions of knowledge have a value far beyond this. Principles are the means by which important facts are fixed and registered. They are means by which our knowledge of the facts they embrace are secured and made available for the future. Disconnected, isolated facts—facts which are not orderly arranged and assimilated into principles—are in constant danger of dying out. Very greviously, I imagine, has the practice of medicine and surgery suffered from this loss. It is painful to think of the multitude of facts which must have been known to the older physicians and surgeons that either have been, or are being, from time to time mislaid by us. Many of these no doubt, in the course of knowledge, have become worthless, being superseded by others, but many, too, had probably a value that now we can neither appreciate nor understand.

Let us look at this matter more closely in its relation to surgery. What place should physiology, for instance, occupy in the study of surgery? I am not speaking now of physiology as a chief instrument of education (a very different matter), but I ask what share it should receive of the time and attention of the student of surgery? Some knowledge of physiology is essential to the surgeon. This statement, I suppose, will be generally accepted. At all events, those who may think otherwise will hardly care to say so in good company. But then how much of physiology is needful for the surgeon? What parts of it may safely be left alone? I would answer shortly, that the principles of physiology should be thoroughly understood by the surgeon, and with these, perhaps, what may be called the leading facts.

For instance, with reference to the circulation, it seems to me that every surgeon should understand the function and mode of action of the heart, arteries, veins, and capillaries; but I do not think that every surgeon need be able throughout his life to state the facts and observations upon which the conclusions are based. I think he should understand the meaning of the capillary circulation and its relation to the other parts of the circulatory system, and the conditions by which the pressure of the blood is regulated; but I should not think it necessary for him to be able always to follow the impressive series of facts through the vegetable and animal kingdom upon which these conclusions are founded. Thus he takes advantage of great principles which have been established on a multitude of facts; and, by intelligent study of a few weeks, he may be spared many months of what might, perchance, prove to him tedious detail.

So with respiration. He should understand, I think, not only the mechanism of the process in man, but the principle on which a respiratory organ is constructed; which are the essential and which the accessory parts. But he need not be called upon to remember always the various forms of the respiratory apparatus in the animal kingdom.

So with digestion. He should, I think, understand what is known of the function of different portions of the alimentary canal, and of the organs accessory to it; but he need not be able to recognise at a glance through the microscope a particular section of every part of it.

Now, assuming, as we have done, that some knowledge of physiology is necessary to the surgeon in ordinary, have his labours in this science, if properly directed, been extended, do you imagine, by its advance? I should say, on the contrary, that they have not only been reduced and shorn of many difficulties, but that, if only his studies be conducted with moderate judgment, he can now acquire much more than formerly upon far easier terms. If any doubt exists in the mind of anyone of what has thus come of the enunciation of principles, or of what I would call leading facts in physiology, let him look over the history of our knowledge of the great subject of development. Of what a mass of hard, dry, almost unintelligible statements it formerly consisted. Now, I do not mean to say that our present knowledge of this subject is free from all intricacy; but as much that was mysterious and doubtful has become clear and plain, I appeal to all who have studied it whether the task has not only been made far more agreeable and profitable, but whether it is not now easier to get it all "up," as the phrase is, in a shorter period of time. And, further, this applies not only to the surgeon properly so called, not alone to one who studies physiology only as a means to an end, but it applies also to those who would study physiology, as Hunter did, with the pure view of its advance. That which occupied Hunter years to unravel may now be gathered up in a few days, and from the point so readily reached the work may still be carried on. The field of labour, the ground which has to be upturned, is happily now no longer the same; but what change is called for in the method of work, what improvement can be suggested of the plan which Hunter pursued?

Now, while for the scientific surgeon a knowledge of the principles and leading facts of physiology will suffice, for the practice of surgery a knowledge is required not only of the principles of surgery, but of as many facts as possible and of detail of every kind. But although in the practice of surgery acquaintance with every fact and familiarity with every detail is of importance, inasmuch as it may be useful in some degree in promoting recovery or alleviating distress, yet in surgery, as in physiology and other sciences, and for the same reason, a knowledge of principles must be always paramount, and it is only by their discovery and establishment that its advance will be secured. Principles are in the practice of surgery what grammar is to language. Men may talk without grammar, speak even good English without knowledge of grammar, and men may practise surgery with little or no knowledge of its principles, just as a mariner may sail in familiar waters without compass or quadrant. But what if strange difficulties should arise?—and is it unusual in surgery to encounter them? What when we pass, as often we are driven, from the well-worn track of every-day experience!

Surely, the great lesson which Hunter taught and teaches, the example he set in the study of surgery, was never more needful than it is now, when every year the strain in this direction becomes more urgent. I think from the time of Hunter to the present we can trace his influence upon the scientific study of surgery through a long line of distinguished men. But the improvement of surgery as an art is not altogether favourable to the progress of surgery as a science. For as the art of surgery advances, and skilful management of detail involves more and more of every surgeon's care and time, the study of principles is in danger of being neglected. There may be less of science because there is more of art. And then the art of surgery is—apparently,

Digitized by Google

at least—the more immediately important. Its application to practice is more obvious and, to the general view, more useful. Above all, it leads to an end by a shorter path and easier steps. To study surgery as a science, and to master its principles, makes a far larger demand on the intellect, and involves higher and rarer qualities than to acquire technical skill in the form, not only of mere manual dexterity, but also in that of familiarity with routine. In a word, the knowledge of the art of surgery means far less expenditure of that which most men are most loth to yield than a study of the science, and secures always a more immediate, and usually, in one sense, a more substantial return. Hence it is popular, and is likely to become still more so. This may be from a certain point of view—which is not the finest—of temporary advantage to particular surgeons, but in the highest sense it is bad for surgery. Moreover, the truth is, that science is never able to accomplish much when held in bondage by the immediate wants of life. Its investigations are successful only when they are pursued with indifference to the uses to which they may be applied.

This suggests, then, a question for the future, the answer to which seems to be hardly an encouraging one. As in each successive year facts and details in every direction—all of more or less immediate importance in the practice of surgery—accumulate, less and less time and attention are likely to be spared for the study and apprehension of its principles, to say nothing of the neglect of the sciences upon which these principles are founded. Is not surgery itself, then, as a science, it may be asked once more, in danger from the extension of surgery as an art? I can imagine there are some who will admit that this is so with very sinister complacency. But what would Hunter have said to it? And, unfortunately, in the present tendency of affairs, what he does say and teach is likely to become unheeded, for it can hardly be expected that the study of his works will survive the decline of scientific education.

The law of division of labour is oftentimes appealed to in this matter, but I venture to think this is not, or at least ought not to be, a case in point. It is often said that as surgery advances, and the art grows more extensive, it becomes more impracticable for anyone to entertain the whole of it. Thus then, first of all, the study of surgery as a science must be set aside by practical men, and then the art must in turn be broken up, the several portions of it being assigned to different practitioners. Now with regard to what is called specialism, let me say at once that I have no word to utter in disparagement of that form of it which consists in a man, first of all, studying and duly qualifying himself in the principles and practice of surgery as a whole, and then at length devoting his attention more especially to the cultivation of some particular department of it. This is not the form of specialism against which I would protest. In my humble opinion, it is in no way an unworthy one, and, if it were, it is by no means frequent. It is no illustration of the law of division of labour as commonly understood, for excellence is not here obtained solely by exclusiveness. But the kind of specialism which should be denounced, and which it is to be feared is not very rare, is that which consists in the practice of some particular portion of surgery without adequate attainment in, or continued study of, surgery as a whole. This is a form of exclusiveness detrimental, I think, to the progress of surgery, and therefore to our profession, both from a scientific and social point of view, and to the public. This I take to be a false application of the law of division of labour, which in manufacture and in many branches of skilled labour is so advantageous, and even inevitable, for ease, rapidity, and cheapness of production, and by which every day human hands are being superseded by machinery. The law of division of labour is, indeed, generally recognised and very useful here, but it is not known, and has no place, in the noblest science or in the highest art.

While, then, we contemplate the genius of Hunter in his works, he has left us an example which is not altogether out of our reach, in his conception of the subject and his idea of the plan of studying it. His view of surgery was more comprehensive, far worthier than that of others. Had he lived with us, would his views, do you suppose, have become narrower? would they have been less remote from specialism? Is it now no longer practicable to study surgery as Hunter studied it? Ay, but to study surgery as Hunter studied it means more than this. For he was great, not only in his understanding, in his apprehension of the nature of the task which lay before him, or in his appreciation of the difficulties of research, but he was great in the spirit with which he encountered them. His patience in ascertaining facts, in investigating questions of every kind, seems to have been wellnigh inexhaustible. It was certainly no habit of his mind to take anything for granted, or, when he could help it, to accept any statement at second-hand. And this was the more remarkable in a man whose mind was ever on the alert for the larger truths beyond, to which facts are but the stepping-stones; for the titles of his various papers very often convey no inadequate notion of their contents. He writes on some fact in natural history which is carefully and accurately described. But very soon it is used in illustration of some principle which is forthwith expounded, or in evidence of some original view which is then set forth, or in suggestion of some further research. Thus the fact, of which only the title speaks, becomes the text of a very valuable discourse. Yet Hunter was also remarkable in this, that the ideas which constantly occupied his mind, and on which he was always at work, still left him with the keenest eye for every novelty which his labours incidentally disclosed, although it lay altogether outside the current of his thoughts. Thus, in addition to the progress he made in the main subject of his labours, he was always accumulating a multitude of what, for the time being, were isolated facts. In this way he must have added largely to his wealth of knowledge.

If there is any point clear in the character of Hunter's work, it is that it was real, genuine, thorough. It may be said, indeed, that this must be true of all good work; but not, I think, in the degree in which it is obvious in his. He is never content with a cursory glance or a superficial view. Even when questions arise in the course of some inquiry, which, so far as that end is concerned, may be lightly disposed of, Hunter almost invariably dwells on them, sometimes at such length and so exclusively as to suggest that he has forgotten the purpose on which he set out. But it is evident that he could not bear to go on his way passing by so much that was undone. This gives a singular character to many of his papers. Much of the apparent want of skill in arrangement and exposition, and the seemingly purposeless way in which oftentimes statement of facts are scattered through his writings, is, I think, due to embarrassment from the riches he had gathered. And the singleness of purpose with which he worked is made evident, not only in the actual result of his labours, for no human being with divided interests could rival such achievements; but in the record, as we have it, of the life he led. He gave not only the whole of his time—yes, the whole of it in no mere conventional sense—and all his great powers, his mind and body alike, to the one object of his life; but to this he sacrificed all that he possessed, all that he could gain. To this he devoted, without stint or scruple, his money, his friendships, all his other interests. What any other man would have consideted impossible he made practicable. And this to no personal end. Careless of all reward save that which was to him paramount—the discovery of truth.

A noteworthy point in the character of Hunter appears to me to be found in the relation which in him thought bore to action. He combined in himself, in a very eminent, I had almost said in a singular, degree, the power of conception and of execution. He not only saw much further, but he was able to do much more than most others. He saw, as Bacon saw, and the idea was probably as original with him as with Bacon, that the systematic and thorough examination of facts was the first thing to be done in science, "and that till this had been done faithfully and impartially, with all the appliances and all the safeguards that experience and forethought could suggest, all generalisations, all anticipations from mere reasoning, must be adjourned and postponed; and further, that, sought on these conditions, knowledge, certain and fruitful beyond all that men then imagined, could be obtained." But he went immeasurably further than the great prophet of science in putting his conceptions to the proof in imperishable work on the lines he had laid down. "I only sound the clarion," said Bacon proudly, "but I enter not into the battle." Hunter sounded a clarion the echoes of which are reverberating still, but he entered into the battle also, was always found where the blows fell thickest, and we are in possession of the spoils. In his Museum there is at once the clearest evidence of the idea and the richest fruits of

Digitized by Google

execution. Bacon, we know, has been compared to Moses on Pisgah surveying the promised land, and Newton to Joshua, who began to take possession of it. But Hunter saw the Canaan of surgery, and took possession of it too.

The mode in which Hunter conducted his investigations in physiology and surgery reminds one of the scientific work of an engineer in laying siege to some fortress. He begins by examining in every way he can the character of the defences; he studies, by every means in his power, its strength of resistance; he measures, to the best of his ability, the difficulties before him. Then, when all this is done, and in nowise previously, he draws out deliberately the plan of attack, arranges the whole scheme of action, and works steadily, patiently, and persistently upon the lines so laid down. It may seem to those who look on in ignorance that time and force are wasted in such elaborate care and toil. But all this means that each step forward shall be well assured, and that there shall be no risk of having to fall back. Ever ready to take advantage of surprises or of dashing assaults, he does not reckon upon these, or allow any part of his design to be made dependent on their success. He goes in to win, not by chance, but by method, and the flag of his country at length floats upon the battlements, not as the trophy of the courage of a forlorn hope, but in triumph of scientific forethought and calculation.

The study of Hunter in his work is instructive, in view not only of what he was, but also of what he was not. What Hunter's acquirements were when he commenced the study of anatomy is not quite clear, and cannot be determined with precision now; but this, at least, may be considered certain—that he could not, at that time, have been called a man of good general education; and it appears certain also that never, at any subsequent period of his career, could he have devoted any care or time to attainments in literature. One result of this defect in him is evident, not only in the absence, in all he wrote, of that which is termed style, but even in the want of power of lucid expression. He cannot always say clearly what he means. His thoughts are too frequently involved in obscurity and confusion.

Very much has been said and written on the rival claims and opposing merits of science and literature; but surely to very little purpose. To compare or contrast the advantages of literature and science—to discuss their relative value even as instruments of education—appears to me to be as futile as to consider the relative advantages or proportionate value of the forces of Nature. Each has its place, its power, and its claims. Each by itself is incomplete, defective. But they are in their purpose correlative, each supplying that which the other lacks, and together, but together only, making the circle of knowledge and education complete. When the champion of science thinks lightly of attainments in literature, or the master of letters speaks with disdain of scientific knowledge, each, I take it, shows only that he cannot appreciate what he does not understand. It is, perhaps, the most conspicuous instance of the evil of that one-sidedness which springs from the inevitable division of labour; of the want of sympathy which is too common in distinguished men with any kind of work outside their own. It is, indeed, natural and necessary that men should become chiefly interested in that which is the daily occupation of their life, that they should prefer, before every other, their own pursuit. But it is unfortunate that we should grow so indifferent, as we commonly do, to the claims of branches of knowledge that we do not possess; and it is still worse if, instead of devoting any spare time at our command to their study, we employ it in denouncing the effort or in expressing contempt for them. In the example of Hunter, one passes over with impatience the numerous disquisitions in which attempts have been made to prove the enormous advantage that Hunter derived from want of education; how much less a man he would have been had he learnt more in his boyhood. No doubt very much depends on the nature of the subjects taught, and still more on the method of instruction. But I confess that to me it seems the education, of whatever kind, must indeed be a very bad one which is not better than none at all. My conviction is that if Hunter had received a good general education in early years, he would have been all the better for it. He would have lost nothing; his mental powers could have been in no way impaired—on the contrary, enhanced. He would have recorded the result of his labours in better order, with more light and greater effect; and we should have had the advantage of a clearer revelation of his thoughts.

But all this is very far from saying that Hunter was not, in the strictest sense, an educated man. He was not, indeed, a scholar. If the subtle rendering of a Greek poet or the skilful turning of Latin verse be the sole test of culture, he gave no sign of it. Of ancient lore he was sadly destitute. In *literis humanioribus* he could have had no place. But if a transcendant knowledge of Nature and her ways, if a firm and ample grasp of her noblest truths, be accounted education, if the devotion through a lifetime of gigantic intellectual powers and of a truly loving heart to the reverent study of God's works be culture, then Hunter, though not a man of letters, was surely a highly educated man.

I do not think that we can now obtain a closer view of the character of Hunter and of his habit of work than that which is afforded by his letters to Jenner. How entirely destitute they are of any trace of literary skill. Even after some correction, how clumsily and awkwardly they are for the most part expressed; evidently not a passing thought bestowed on their composition. But how they always struggle, often how straight they go, to the point. Always full of the subject of his work, they must thoroughly reflect the disposition of his mind at the time he wrote them. Careless of all form, and of everything else, save to get out of Jenner some information he wanted; now seeking directly for some knowledge which he believed Jenner to possess; now suggesting some inquiry that Jenner might make for him; sometimes plainly dictating the method of it; then begging boldly for some animal or other specimen which he coveted; occasionally only a word of persuasion or encouragement, or even an attempt at bribery, lest Jenner should grow weary of well-doing. All outside matters, whether public or private or domestic, ignored; except at rare intervals, when it is comical to see, as anyone may easily, that a sense of unbecoming neglect of these small ceremonies strikes him, and then we are surprised by some polite sentence in conclusion. Once, indeed, there is an attempt to console Jenner for some disappointment in love by the assurance "I shall employ you with hedgehogs." But the whole correspondence tells a simple tale of indefatigable industry, of unquenchable energy, of singleness of purpose and unbounded sacrifice; of determination, heedless of cost and difficulty and all else, to seize every possible opportunity of accumulating knowledge.

The fame of Hunter, after all, falls far short of him. It may, without exaggeration, be said that he is really greater than to most men, even to most surgeons, he appears to be. And the reason of this is not far to seek. Neither the genius nor the labour of Hunter is of a kind that at once strikes the inquirer, or can be readily understood by the student. He made no startling discovery, in the popular acceptation of the term, which can be discerned at a glance and appreciated by everyone. As we follow, one after another, the successive, or oftentimes, as they really were, the simultaneous works of Hunter, we may remark the absence of any apparently great intellectual feats; we are never dazzled by the brilliancy of particular achievements. We may, indeed, say of very much of what he did that it might have been produced by any very intelligent, thoughtful, and industrious man devoted to his subject. With regard to separate portions of it, we can very rarely go beyond this, and exclaim, as a famous author tells us that he did, as he threw down his pen over one of his own passages, "By Jove, that is a stroke of real genius." In this respect, Hunter will not compare favourably with some far below him in scientific rank. His work, in order to be fully appreciated, must be studied throughout. It is not, of course, of uniform excellence. But Hunter's fame does not rest altogether on any particular part; indeed, it may be said that any particular part might be withdrawn without any material loss to our estimate of his power. We might select examples of it to illustrate his ability in this or that direction—as, for instance, his skill in inquiry, to his researches on the increase of temperature in inflammation, and his experiments on the transplantation of the cockspur, and on the growth of bones; his sagacity, to his inference, from the character of their contractility, that the arteries are muscular; the soundness of his judgment, to his reflections on the coagulation of the blood. But I venture to think that no separate fraction of his work will enable us to grasp his conception of the plan on which surgery should be studied, or the progress which, in a few short years, he actually made in its execution. It is only after a review of the whole of his vast labours in their mutual relation—not merely after a study of the merits of his numerous papers, each taken by itself, but in an attempt

Digitized by Google

to apprehend the scheme to which, as it appears to me, all his labours were subservient—that we are, in any measure, able to realise the strength of Hunter's genius.

Then, as the chief merit of his work is not of a character to catch at once the eye, even of one who searches for it, so his subject is not one of widespread or popular interest. I can well imagine that, of all men who have achieved greatness, Hunter requires to be studied with most diligence. The more so because of the absence of all literary skill. And there can be no doubt that he shared the fate of all those who have been, like him, in advance of their time. He was so far beyond his contemporaries as to be, for the most part, out of their reach, and therefore they left him alone. And even his successors have not always found him out. It may, indeed, be said to have been almost by an accident that in association with the possession of his Museum we have periodically a festival in honour of his memory. Yet, even with all this, how much time is devoted at the present day to the study of his works? Nay, dare I ask the further question here, Can every one of us who call ourselves surgeons say that he has read them?

Such then, at least in the eyes of one who, though from afar, has long and earnestly looked up to him, was John Hunter. Beyond all cavil, if the word have any meaning for us, a man of genius; a man supremely endowed with power and faculties for the discovery of truth. With little education at the outset of life, without the advantage of the schools, he found himself face to face with the deepest and most mysterious problems of Nature. And he was forthwith able to take full measure of the magnitude of the task. It seems never to have occurred to him that he could snatch an answer by surprise; that a solution could be reached by any short or sudden means. But his survey assured him that upon one plan only, but by that abundantly, could success be made certain. So with patience, which of itself has been called genius, he went back to the beginning. It was genius, too, and that of the highest order, to discern at so vast a distance where that beginning lay. But there he placed himself, and from that point went forward only when he had made each footstep sure. Who shall say that his imagination was not fertile or that he faltered in the use of it? Yet no seductive theory tempted him into undue haste; and though sometimes drawn aside by a specious speculation, he seems hardly ever to have been lost in an unsound conclusion. And when he fell, the treasures he had won were found not only in the multitude of facts he had garnered, or even in the principles, which by virtue of the facts he had discovered were made plain; but also in the very plan and purpose of his work. For from the height on which at length he stood, not only can the path he trod be clearly traced, but the highway thenceforward is disclosed. So is the greatness of John Hunter to be estimated, not only by what he discovered, but rather by the lesson and example of his work. Truly it may be said of him that he did much. Truly it may be said of him that he showed how much more is to be done.

"He, being dead, yet speaketh"—still speaks to us as no other man before or since has spoken. But when and where can his voice be heard most plainly? Are the spirits of those who have shaken off "this muddy vesture of decay" permitted to revisit the scenes of their earthly labours? Can they still be with us on our way? If the soul of this mighty son of science is ever in our midst, surely his favourite haunt must be now within these walls—in the Museum which will soon almost surround us—at once his most graphic and glorious monument. The memory of Hunter, like the memory of the greatest men of every age, is imperishably enshrined. Art, in her noblest efforts, has striven to make his form familiar to us. His name is stamped in indelible characters on the records of human progress. But, before all, he lives in and draws the breath of life from his own immortal works; and of these, none can be so truly a memorial of the very man as this; no other can so resemble him, can possess so much of him, can tell so fully of what he was; can so perpetuate him in the vast store of facts, in the purpose for which they are set forth, in the illustration of principles, in the suggestion of truths beyond those it can show, above those it can reach; in all this, I say, no memorial, however majestic, can rival our Museum. The foundation of this with his own hand and his whole heart he laid; it has grown, and still is growing, from his strength, and it must be made for ever worthy of his name.

Harveian Lectures

ON

CANCER OF THE UTERUS.

BY J. WILLIAMS, M.D. LOND., F.R.C.P.,
OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE III.

(*Concluded from page 303.*)

MICROSCOPICALLY, there are two forms of cancerous disease of the body as of the cervix—adenoma and true cancer. The changes in the glands in adenoma are of two kinds: the cells may retain pretty much the character of the epithelium of the glands in health, or they may be somewhat smaller, but regularly formed, or they may be larger. Dr. Matthews Duncan first described a case of adenoma of the body of the uterus; the disease was polypoid, and was removed. In true cancer, the cells lose their shape, becoming angular, many-nucleated, and fill the lumen of the glands. The changes often call to mind scirrhus; and Mr. Stanley Boyd, after examining such a case for me, and finding in the growing part that the disease grew from the glands, suggested that all cancers of the body were columnar epithelioma. This has been shown to be so; for of all the cases examined by Ruge and Veit and myself there was no instance in which the disease grew from anything but the epithelium of the glands or of the surface. The direction which the growth takes is similar in some respects to that taken when it attacks the cervix primarily. It involves the whole surface of the body, but tends to respect the cervix. In the later stages, however, it passes beyond the inner orifice and attacks the cervix, and extends down as far as the os externum. It spreads deeply, involves the muscular wall, and may pass through it, giving rise to inflammatory exudation on the peritoneal surface and adhesions to neighbouring organs, and then it invades the adherent parts. In one of my cases it had opened the intestine; in another it had all but caused a fistula between the small intestine and uterus; and in one it had passed through the uterine wall into the broad ligament, where it had formed a considerable tumour. The glands affected are those in the broad ligament and those along the spinal column. Secondary deposits may be present in many organs—as the lungs, liver, and kidneys. Its structure is always glandular.

In all my cases the disease began after the menopause. One patient was fifty-three years of age, one fifty-four, and one sixty-three. Of Ruge and Veit's cases two were under forty, the youngest being thirty-two. One was between forty and fifty, six were between fifty and sixty, and seven were between sixty and seventy. So that the disease is rare under fifty and before the menopause, and about as frequent between fifty and sixty as between sixty and seventy.

With regard to childbearing, five women had never been pregnant, four had had one child, and nine had been pregnant twice or oftener. So that we find thirteen out of eighteen had been pregnant and five had not, showing a much larger proportion of sterile women suffering from cancer of the body than from cancer of the cervix.

Hæmorrhage is the symptom which usually attracts the patient's attention and points to the existence of the disease. After the menopause bleeding sets in, and frequently returns at tolerably regular intervals, and women think that menstruation has returned. It is often profuse, but sometimes only slight. It is said to increase as the disease progresses. It is, however, not characteristic, for it is present in the endometritis of old age, and in certain forms of ulceration of the cavity of the body called lupus. There is generally present an offensive discharge.

Pain is a common symptom; and in some cases it comes on at stated hours and lasts for a longer or shorter time, and is of great severity, as was pointed out by Simpson. It is believed to be due to contraction of the uterus. In all my cases cachexia was present in a marked degree.

I regret to have to pass over these matters so briefly, but it appeared to me that the questions I have discussed in the previous lectures are of far greater importance in their bearing upon the great aim of practitioners than the

Digitized by Google

enumeration or the discussion of symptoms to be found in all works on the diseases of women, and I therefore felt it necessary to devote most of the time at my disposal to them. I must now point out the bearing of what I have already said upon treatment.

I do not propose to discuss the palliative treatment of cancer of the uterus. With this you are all well acquainted from experience in your own practices. It is the common property of all practitioners, and is in the main fully given in all works on medicine, and the part of it which is specially applicable to cancer of the uterus is given in all works on the diseases of women. It consists mainly in the relief of pain and the practice of cleanliness, while in some special cases particular means may be called for to arrest hæmorrhage and other discharges. These I pass by, and proceed to discuss the radical methods of treatment which have been practised during the last ten years. These methods are two—the supra-vaginal amputation of the cervix and the total extirpation of the uterus. Freund of Strasburg introduced or reintroduced total extirpation into practice some dozen years ago. He practised it by abdominal section, and the results of this method proved disastrous, the mortality from it amounting to 72 per cent. at least. This method was modified by Czerny and others, who amputated the cervix by the vagina first, and then performed abdominal section to remove the remainder of the uterus. Schroeder subsequently described what is known as the vaginal method, in which the whole of the organ is removed through the vaginal canal; and by this method much greater success has been obtained, so far as the immediate mortality after the operation is concerned, than by the abdominal, for about 72 per cent. of the cases operated upon recover from the operation.

Amputation of the cervix has been practised for many years, but only recently in the way it is done now. I am not going to describe these operations further than I am obliged to, but I want to show the bearing of what I have told you in these lectures upon the application of the two methods—total extirpation and partial extirpation of the uterus. That you may follow me, I must remind you of what I said about the sites of origin of cancer and the lines of its growth. And, in the first place, cancer of the vaginal portion begins in the squamous epithelium; it is superficial, and remains superficial for a long time; it spreads towards the vaginal vault and along the vaginal walls superficially. In these cases the whole of the disease, provided it is limited to the uterus, can easily be removed; indeed, in most cases, if the lower half of the cervix be removed, the disease will be extirpated from the uterus. The difficulty arises after the disease has spread beyond the limits of the portio vaginalis into the vaginal vault, and lies in the obstacles to the removal of a large superficial area, owing to the conformation of the parts—the near proximity of the bladder and ureters especially. Many cases have been cured by amputation of the cervix, or of a portion of it, with the écraseur. Recurrence takes place superficially at the edge of the cicatrix, and not in the deeper structures, and consequently no advantage would be gained by total extirpation of the uterus.

In the next place, we have to discuss the applicability of total and partial extirpation to cases of cancer of the cervix proper, first of all, in the light of pathology. In the last lecture I pointed out that cancer may begin in the cervix in two situations—in the lower part near the external orifice, or in the upper part near the internal orifice. I showed that the tendency of the disease was to grow downwards towards the portio vaginalis, and outwards towards the parametric connective tissue. It does not spread upwards into the body of the uterus except in rare instances and in the late stages of the disease, when no operation can be undertaken with any hope of effecting a radical cure. Before it has involved the whole of the cervix, it has probably in some places invaded the parametric tissues, and this is the case long before the body is attacked. Under these circumstances, what are the advantages, if any, of total over partial extirpation? The lines of incision in the vaginal walls can be made in the same situation in amputation of the cervix as in the operation for total extirpation, so that in this respect total extirpation has no advantage over the minor procedure. Then, in both operations the dissection in front is made in the cellular tissue between the uterus and the bladder. It is generally advised to tear through this tissue after the vaginal walls have been cut through. The dissection can be made in both operations as far as the reflexion of the peritoneum from the uterus on to the bladder. On the sides, again, the dissection can be made at the same distance from the uterus in amputation of the cervix as in total extirpation. With regard to the dissection posteriorly the proceeding is usually somewhat different in the two operations. In the minor operation the vaginal wall is divided as far as the peritoneum, but the peritoneum is not opened; it is peeled off up to the point where it is firmly adherent to the wall of the uterus. In the major operation the peritoneum is opened over the place where the incision is made in the vagina. This in many cases—cases in which the disease has involved the posterior wall of the cervix deeply, and invaded the parametric tissue—is a distinct advantage. It is, however, an advantage which can be made available in the minor operation; for in amputation of the cervix the peritoneum is often deliberately opened, and this does not appear to add greatly to the risk incurred. As far as we have gone, then, total amputation presents no advantage over supra-vaginal amputation.

But what are the facts with regard to the entire removal of the disease from the uterus itself, and the prevention of recurrence. How much of the uterus can be removed by the minor or less severe operation? Can enough be removed to ensure prevention of recurrence? In reply to the first question, I say the whole of the cervix can be easily removed, and a great part of the body can also be removed. When the reflexion of the peritoneum has been reached, the dissection can be carried up in the uterine wall near the peritoneal surface, and a cone-shaped piece of the body reaching up to the fundus can be cut out. This was done in Case 16. In that instance the mucous membrane of the fundus was removed, together with that at the internal orifices of the Fallopian tubes. This was done without injury to the peritoneum; so that the entire uterus can be removed, except a shell of the upper part of the body. But is this sufficient to prevent recurrence? Is the risk of recurrence greater or not when a part of the uterus is left behind? I believe it is not any greater, and on grounds which appear to me to be sufficient; for in six cases in which recurrence took place, in four the stump remained healthy, and in one it was superficially and clearly secondarily affected. In all recurrence took place in the parametric tissue, and in four in that only. This evidence points clearly to the possibility of extirpating cancer entirely from the uterus by supra-vaginal amputation, and shows that, in so far as the prevention of recurrence in the uterus is concerned, total extirpation of the uterus presents no advantages over partial amputation. But how about recurrence in the parametrium? Will total extirpation help us to prevent this mode of recurrence more than amputation of the cervix? I think not. I have shown that the line of dissection around the cervix up to the level of the inner orifice or the reflexion of the peritoneum is the same in both operations; that the peritoneum can be and often is opened at the same level frequently in amputation of the cervix, as in the operation for removal of the whole uterus; that, in fact, the tissues in the area of recurrence are cut through in the same planes in both operations, and therefore that one presents no advantage over the other. It has been suggested, however, and I believe practised, to remove a portion of the bladder when the cancer has invaded the connective tissue between that organ and the uterus. This could be done in the minor operation without increased risk; but I imagine that it would greatly enhance the danger of the operation for total removal of the uterus. So that, if anything is to be gained by such a procedure, this gain would be in favour of the minor operation. I doubt, however, whether such a proceeding would be likely to possess any advantage over the ordinary method.

In so far, then, as the natural history of cancer of the portio vaginalis and of the cervix throws light upon the value of operations for its cure, it appears that supra-vaginal amputation of the cervix is quite as satisfactory an operation as the removal of the entire uterus. But what does the experience of operators tell us on this point? Does it accord with the conclusions we have arrived at upon pathological grounds? A large number of patients have been operated upon for cancer as well as for other conditions, and the results of the operation have been recorded in societies or published in journals soon afterwards, and long before the cases were completed by observation of the permanent results. All these cases are absolutely of no value for our purpose. I cannot conceive any good object in operating upon a patient

Digitized by Google

on a Monday and reporting the case on a Thursday and then burying it out of sight for ever. The cases which have been watched for years after operations for cancer are comparatively few. I do not profess to know them all, and I shall therefore take the results obtained in the Vienna Hospital published by Pawlik and those of Schroeder published by Hofmeier. They are the largest and most complete. Those of Martin of Berlin and those of Fritsch of Breslau are for my purpose and for purely scientific purposes valueless, because the cases had not been watched for a sufficient length of time to determine whether recurrence took place or not. They are useful for the purpose of estimating the mortality of total extirpation only.

Recurrence may take place early or late, but if a considerable time has elapsed before its appearance it may be inferred that the reappearance is not a recurrence, but a new development; for just as a new development of cancer may take place in a part of the body quite independently of cancer in another part, so may a new growth appear in the stump of a uterus whose cervix had been amputated for cancer independently of the cancer which was removed. I consider, and I believe justly, that if recurrence does not take place in the course of two years a cure has been effected, and that should the disease break out after the lapse of that time the new growth is not a real recurrence, but a new development. Bearing this in mind, we find that Pawlik reports thirty-one cases of cancer of the portio and cervix which were cured by amputation of the cervix. One hundred and thirty-six cases were operated upon. Of these thirty-three remained in good health at periods varying from one to twenty years after the operation. Pawlik operated by means of the galvanic écraseur, and opened the peritoneum thirty-nine times. Of 105 partial operations performed by Schroeder ten died; the fate of seven is doubtful; recurrence took place in forty-three during the first year, and forty-five remained well; thirty-one remained well at the end of two years; twenty-three remained well at the end of three years; one had died of cancer of the bones, one of cancer of the ovary, and three had recurrence, the state of one was doubtful, and two were lost sight of. If we now compare this result with that of total extirpation in Schroeder's hands, we find the uterus extirpated during the same period in forty cases, with ten deaths. Recurrence took place in fifteen during the first year, and one was lost sight of, leaving fourteen healthy at the beginning of the second year. Recurrence took place in seven during the second year, and in one case the point was doubtful. Four were known to be healthy. We have therefore about 30 per cent. in good health after partial operation, and only ten after total operation—that is, of those operated upon; and nearly 35 per cent. of those who recovered after partial operation, and 13 per cent. after total extirpation. It should not be forgotten that these cases of total extirpation were cases of more advanced disease than those in which partial extirpation was performed; or, at least, that they were cases in which the disease had involved the uterus to such an extent that partial amputation was thought to be insufficient.

Hofmeier, who reports Schroeder's cases, divides cancer of the lower segment of the uterus into cancer of the portio, cancer of the mucous membrane of the cervix, and cancer of the cervical tissue. For cancer of the portio he advocates amputation of the cervix; for the other forms, total extirpation of the uterus. All the cases in which he had observed a long and lasting recovery after total extirpation were cancer of the mucous membrane. The results obtained in cases of cancer of the cervical tissues are much more unfavourable. He states that "this form of cancer is not discovered until it has existed for a long time, until ulceration has taken place, total extirpation is indicated for the disease may have extended into the body. The prognosis is very unfavourable, and recurrence is most frequent in them." I cannot accept Hofmeier's classification of cancer of the lower segment; but it should be said that his paper is purely clinical, and not in any sense pathological, so that I lay but little stress upon his division. He does not describe the seat of the recurrence, but as the whole uterus was removed it must have taken place in the parametrium, and in so far his observations are in accord with mine; and as the recurrence takes place not in uterine but in connective tissue, it cannot be said that total extirpation is indicated in these cases. Moreover, he shows that of the forty-three cases in which recurrence took place during the first year after partial amputation, in only two did the recurrence take place in the uterine stump. In all the others its seat was the cellular tissue, and therefore, as a rule, total extirpation is not indicated. Clinical experience appears, therefore, to point to the same conclusion as pathological investigation—that is, that in cancer of the portio vaginalis and cervix total extirpation of the uterus possesses no advantages over supra-vaginal amputation of the cervix, because the tendency of the disease is, not to invade the body of the uterus, but the parametric tissues. In cancer of the uterine body there is but one operative procedure which holds out any hope of a radical cure, and that is total extirpation.

There is one other question in connexion with the operative treatment of cancer of the uterus upon which I wish to make a few observations, and that is the indication for operating. All cases of cancer should be operated upon provided they are met with at a period sufficiently early to justify the hope of effecting a radical cure. But what are the physical signs which justify this hope? The pathological condition which justifies it—be the cancer in the portio vaginalis, the cervix, or the body—is that the disease has not passed beyond the uterine tissues. This, however, is not easily discovered either before or during the operation. Frequently, indeed, the after-results prove that it was too late, even in cases which appeared to be favourable. The physical signs generally relied upon are mobility of the uterus, absence of induration around it, and absence of affection of the glands. In endeavouring to establish these points, the examination should be made under an anæsthetic, and the whole pelvis should be explored by the vagina and by the rectum. In spite of every care, however, clinical investigation may mislead, because the disease may have passed beyond the limits of the uterus and yet give rise to none of the physical signs mentioned. The pathological condition present is most easily established by clinical examination in cancer of the portio, for when the disease has reached the vaginal vault it gives rise to superficial induration at the place invaded, and this is more easily discovered than when induration of a slight degree is present in deeper tissues. In such cases, and indeed in all cases, the rule should be to make the incision in the vaginal wall wide of the indurated part. In this means alone lies any hope of preventing recurrence.

In cancer of the cervix proper the investigation is much more difficult, for the uterus may be freely movable, the mobility of the organ may be unimpaired, no indurated tissue may be discovered, and no enlarged glands may be found, and yet the disease may have passed into the cellular tissue around the cervix. I have seen several such cases, and in them the tissues through which the incisions were made appeared to be healthy. I know of no way in which the difficulty can be overcome. Coarse induration can be readily discovered—that points to an advanced stage of cancer; but the commencement of infection of the parametric connective tissue will escape the most sensitive and cultivated touch. If the parametrium is free, no anxiety need be felt about the degree of extension of cancer upwards towards the body. It can be entirely extirpated in that direction. The difficulty is to extirpate it in a lateral direction, according to both pathological and clinical research. The difficulty is sometimes just as great in cases of cancer of the body. The tendency in these cases is to invade the broad ligaments and peritoneum or adherent intestines. I have seen one case in which the uterus was movable without surrounding induration or large glands, and yet the fundus was adherent to a coil of small intestines, and the disease had invaded the wall of the intestine and almost formed a utero-intestinal fistula. This patient was examined under ether, and yet the condition escaped detection. In spite of these difficulties, and in spite of recurrence, the operative treatment of cancer gives in many respects satisfactory results, and this is especially true of cancer of the portio vaginalis and cervix. Sometimes permanent cures are effected, while in a large number a respite for one or more years is given. In Schroeder's cases the respites were as follows: Of 105 partial operations, 10 died, the fate of 7 was doubtful, and recurrence took place in 43 during the first year; so that 45 had a respite of one year, 41 of eighteen months, 31 of two years, 27 of two years and a half, 23 of three years, 17 of three years and a half, 10 of four years, 7 of four years and a half, 7 of five years, 3 of six years, and 1 of seven years. Besides these cases, which remained under observation, many were lost sight of and their fate was not known. Of 40 total extirpations 10 died, 14 had a respite of one year, 8 of eighteen months,

Digitized by Google

4 of two years, 2 of three years, 1 of three years and a half, and 1 of four years and died of apoplexy.

I thought at one time that recurrence caused more and earlier suffering than the primary disease, because it affected the deeper tissues sooner than the primary disease would have done, but a larger experience of such cases has convinced me that I was in error, and that the pain depends on some peculiarity in the patient or in the disease, for many recurrences are painless. I cannot speak of the duration of the disease after recurrence. I have not a sufficient number of cases, but I have seen it last from four to eighteen months. It is not impossible that a more careful study of the pathology and natural history of cancer of the uterus will help us much further in its diagnosis and treatment, and the earlier we are enabled to make the diagnosis the more successful will our treatment prove. No haphazard and blind procedures of treatment will prove of any avail; the only method which can give us a sound and firm basis upon which to build is patient study in the laboratory as well as at the bedside; and although I would in no way depreciate clinical research, yet I cannot help thinking that the investigations conducted in the laboratory, in the present state of our knowledge, are the more likely means to give us light upon cancer of the uterus—to elucidate the laws which govern its development and growth, as well as those which should guide us in our treatment.

CASES OF GALL-STONES, WITH REMARKS.[1]

BY J. S. BRISTOWE, M.D., LL.D., F.R.S.

THE subject of gall-stones is always one of great practical interest, but it is much too large to be dealt with exhaustively in a short paper. I prefer on this occasion only to bring under notice two cases of special interest which have come under my care during the last year or two—cases which illustrate in different ways the phenomena which attend the escape of gall-stones by ulceration from the cavities or channels in which they are formed. The first case is one in which jaundice (due to partial obstruction to the flow of bile from the liver) of twenty years' duration was followed by the formation of an abscess in the lower part of the right side of the abdomen, and the escape, together with pus, of large quantities, not of true gall-stones, but of biliary gravel. The second case is one of the escape through an ulcerated opening of a large gall-stone from the gall-bladder into the duodenum, and of death from consequent obstruction of the small intestine.

CASE 1. *Gall-stones and gravel causing suppuration, and discharged through the abdominal walls below the level of the umbilicus.*—Ann A——, unmarried, a governess, aged thirty-eight, came under my care on May 16th, 1884. Had always had weak health. Had rheumatic fever when six years old, and when twenty a second attack followed by typhoid fever. As long as she could recollect she had been liable to "spasms" commencing in the left hypochondriac region, and extending thence obliquely into the right lumbar region. Had been jaundiced for twenty years, the jaundice varying in intensity, but never disappearing. Her illness dated from the previous October, when she had an attack of "spasms" lasting for ten days, which left her very weak. After this she first discovered a small lump on the right side of the abdomen. This tumour had been enlarging ever since. Owing to constant pain in the situation of the tumour and to debility, she took to bed, and only left it in order to come from the country to the hospital. The journey caused great aggravation of pain.

The patient was spare, but not markedly emaciated; pale, and quite obviously, though not deeply, jaundiced. The conjunctivæ were yellow. The abdomen was not generally distended or hard; but on the right side, extending vertically from a little above the level of the umbilicus above to the groin below, transversely from the left of the mesial line to the anterior superior spine of the right ilium, and having a superficial extent about equal to that of the palm of the hand, was a hard mass, the edges of which were not very well defined, and which appeared to be incorporated with the deeper parts of the anterior abdominal walls. It did not move with respiration or under the skin; but it moved with the movements of the abdominal walls. It was slightly nodulated, the more prominent parts seeming to infiltrate the parietes as if coming to the surface. It was dull on percussion, and no resonance could be obtained between it and the liver. She complained that it was tender, and after it had been handled she suffered from much lancinating pain in it. Tongue clean, appetite poor; thoracic organs all healthy. Catamenia regular; urine of specific gravity 1030, and containing neither sugar, albumen, nor bile. No enlargement or disease of any organ within the abdomen could be detected; and at this time it was uncertain whether we had to do with a malignant tumour invading the abdominal walls or a suppurating inflammatory mass. Against the latter view were the facts that the tumour had been growing for six months, that it was uniformly hard and free from all sense of fluctuation, and that the temperature was scarcely above the normal.

During the ensuing twelve days the patient's general health improved; and, indeed, on the whole she seemed fairly well, excepting that she suffered at times from severe pain in the tumour, which had to be allayed by morphia injections. During this time, however, the tumour got more tender, and therefore more difficult to examine; it enlarged somewhat; it became more definitely adherent to the skin at two or three points, and the skin in these situations presented a blush of redness. At length one of the prominences became somewhat yielding, and, although it did not fluctuate, it was thought well, on consultation (on March 27th) with Mr. Sydney Jones, to make an exploratory puncture. A small incision was made, and a few drops of thick pus oozed away. A probe was then inserted for a couple of inches or so. It passed pretty easily in two or three directions, not into any definite cavity, but apparently through tissues infiltrated with pus. A deep incision about two inches long was then made; and thence a considerable quantity of thick pus escaped.

Up to this time the temperature, though generally normal, had been in the habit of rising occasionally to 100° or 101°; but after the operation all traces of fever disappeared; the health and appetite improved; she lost the abdominal pain; a slight discharge of pus continued; and the tumour diminished markedly.

On the morning of June 3rd, on removing the poultice, several rounded black bodies, varying from the size of a coriander-seed downwards, were for the first time found in the discharge. These were rough on the surface, and readily crumbled between the finger and thumb into a coarse powder. They were insoluble in ether and in chloroform, and gave the reaction of bile when treated with nitric acid; they were obviously biliary concretions. From this time scarcely a day passed in which a greater or smaller number of biliary concretions failed to be discharged. They varied from mere dust to friable masses as large as a small pea, and, like those first observed, were always black and structureless, and formed essentially of biliary colouring matter.

As (although the patient's health continued to improve, and the abdominal pain, tenderness, and lump had all much diminished) the discharge of pus and of biliary concretions continued, it was determined at a second consultation with Mr. Jones to enlarge the incision (now partly healed) in the upward direction towards the gall-bladder, in order, if possible, to remove the accumulation of concretions which were obviously retarding the patient's recovery.

On June 24th the patient was put under the influence of ether, and Mr. Jones passed a probe through the wound upwards and to the left to a point two inches to the right of the umbilicus and half an inch below it. He then slit up the sinus, and from its upper point passed his finger into a prolongation of it, which extended upwards in the presumed direction of the gall-bladder. The tissues around were dense and cicatricial in character; and in the sinuses themselves, and mainly in the upper one, were found large numbers of friable calculi and much biliary gravel of the same kind as those that had been previously discharged. The wound and its diverticula were washed out freely with a weak solution of carbolic acid, and a drainage-tube was then inserted. The patient took the ether badly, became very blue during the operation, and at the end of it almost ceased breathing, and had to be revived by artificial respiration. She fainted several times during the evening, and afterwards suffered from sickness. A good deal

[1] Paper read at the meeting of the Hertfordshire District of the Metropolitan Counties Branch of the British Medical Association, Nov. 20th, 1886.

Digitized by Google

of biliary fluid was discharged from the wound in the course of the afternoon and evening.

For about a fortnight after the operation she continued very weak, suffered a good deal from pain in the wound, and in the abdomen in its neighbourhood, and often fainted two or three times a day. Then she began to improve in health manifestly, and to gain flesh and strength, and on August 10th sat up for the first time. After this her progress towards health was rapid, and almost uninterrupted.

Notwithstanding the great amount of calculous matter removed at the operation, large quantities of calculi, varying from rounded aggregates a quarter or one-third of an inch in diameter to grains like those of ground pepper, escaped daily from the wound with the fluid discharge. From twenty-five to fifty were not unfrequently discovered daily. The abdominal hardness gradually decreased, and the wound healed excepting at its upper point, where a drainage-tube was retained, and the fluid discharge escaped. The yield of stones diminished latterly, and none were observed after Sept. 19th. The sinus remained open, however, and discharged a good deal of thin colourless fluid as long as the patient remained in the hospital.

On Sept. 10th she had an attack of severe lancinating pain in the left hypochondrium, which lasted for about an hour and a half, and was followed by diarrhœa, and it was thought some increase of jaundice. She said the attack was exactly like those to which she had been liable.

The patient left the hospital on Sept. 30th, still with a small weeping sinus, but in good flesh, much improved in strength, and able to walk about, healthy in appetite, free from abdominal pain, and cheerful. But she was still jaundiced, as she had been all along. The skin had a pale brown tint, and the conjunctivæ were distinctly yellow. But there was not, and there never had been, any bile in the urine. The concretions discharged from the wound on several occasions were very carefully examined, both chemically and microscopically, and proved to consist almost exclusively of biliary colouring matter. I have not seen, but have several times heard of, the patient since she left the hospital, and believe that she remains well.

It is, of course, not uncommon for ulceration to take place in the gall-bladder, in consequence of the presence of stones in it, and for these to be discharged from an ulcerated opening over the site of the inflamed cyst. But the case just narrated is not an ordinary one of this class, because: first, there was a history of biliary obstruction of twenty years' duration, which was not removed by the treatment which relieved the patient in other respects; second, the local evidences of inflammatory thickening and suppuration appeared at a considerable distance from the situation in which they might have been expected to show themselves; and third, the concretions which escaped were not ordinary gall-stones, but amorphous granules of biliary colouring matter.

Abscesses arising in the abdomen not unfrequently present in situations which are remote from their seat of origin, and especially have a tendency to gravitate into the venter ilei or pelvis. And more than once I have seen an abscess of the liver which had communicated with the cavity of the lesser omentum, or had opened into its substance, lead to considerable inflammatory thickening of the implicated tissues and their permeation with sinuses, to adhesion between them and the abdominal walls, and finally to perforation of the latter at or near the umbilicus. In this case the inflammatory phenomena corresponded in the main with those just described; and I am inclined to think the abscess had been conducted downwards by the tissue of the great omentum, and that the peculiarities which were observed were largely determined by this circumstance.

The concretions were amorphous, and presented a vitreous fracture; and, if cholesterine was present in them at all, it was present in exceedingly minute quantities. I never saw such concretions in the gall-bladder, and am inclined to think they are never found there. They were such concretions, however, as not unfrequently form in the gall-ducts, and tend to coalesce or grow into calculi, which become moulded to the channels in which they lie, and usually present a more or less tuberculated surface. I am consequently inclined to think that in this case the gravel came, not from the bladder, but from the ducts; and that the abdominal abscess originated in ulceration of one of the ducts, probably the hepatic or common duct.

The long duration of jaundice in this case cannot, I think, be directly explained by the passage of gall-stones, unless, indeed, as sometimes happens, the irritation caused by them determined the formation of a stricture at the point at which the common duct opens into the bowel. But if such a stricture had been an early result of the passage of a gall-stone from the gall-bladder, one might have expected that the passage of subsequent stones from the gall-bladder into the bowel would have been prevented, and that their accumulation in the common duct would long ago have led to absolute obstruction, and to a fatal issue. But I could not satisfy myself that the spasms to which the patient was liable were typical attacks of gall-stones, or that there was any clear evidence that the jaundice commenced with such an attack. I am inclined, on the whole, to think that her illness began with a seizure of catarrhal jaundice, which induced permanent thickening and stricture, but not complete obstruction of the lower end of the common duct, and that, following upon that, permanent yet variable jaundice supervened, associated with general dilatation of the hepatic ducts, and tendency for the retention of bile in them, and for the deposition of its solid constituents in a granular form. If this view be correct, the spasms might be referred to the occasional passage of gravel.

I recollect a patient of mine, a middle-aged man, who was suffering from jaundice of some years' duration, but who still passed bile in variable quantities into the bowel, and died ultimately from profuse hæmorrhage (I think from the nose), whose jaundice we found after death to have been caused by such a stricture as I have assumed to exist in the present case, a stricture barely admitting the passage of a very fine probe.

I may here add a remark with regard to the abundant presence of cholesterine in gall-stones formed in the bladder. The general belief, I think, is that this substance is precipitated from the bile around solid nuclei, the origin of which I need not now consider. But cholesterine forms a very minute proportion of the solid constituents of the bile; and it is odd, therefore, that the great bulk of these calculi should consist of cholesterine with only a trace of other bile constituents, and sometimes even of pure cholesterine; and it becomes especially odd when we bear in mind that biliary concretions formed in the ducts generally consist of the solid constituents of the bile, and present little or no cholesterine. Many years ago I examined a patient in whom there was a contracted gall-bladder with extremely thick walls. Embedded in these walls were a considerable number of cavities varying between the size of a pea and that of a bean, which were evidently dilated mucous crypts. And within each one of these were large crystals of pure cholesterine. These were colourless, rhomboidal, varied from $\frac{1}{8}$th to $\frac{1}{4}$th of an inch in breadth, and were about the $\frac{1}{10}$th of an inch thick. I was led from the facts of this case to assume, and I am inclined to think, that the bulk of the cholesterine in gall-stones formed in the gall-bladder is derived, not from the bile, but from the secretions discharged from the mucous surface.

CASE 2. *Obstruction of ileum by a gall-stone: death; necropsy.*—Ann S——, a married woman sixty-five years of age, was admitted under my care on March 24th, 1885. Her history revealed nothing of any importance, excepting that she had had no symptoms at any time pointing to affection of the liver or its excretory apparatus. Her illness began on March 20th with retching and vomiting, which continued, with varying, but on the whole increasing, severity up to the time I saw her. The vomit during the last two days had been offensive. The bowels had not been relieved for two or three days previously to the onset of her illness, and they had not been relieved since. She had passed little urine, and passed it only on one occasion since the 22nd. It was then small in quantity, high-coloured, and turbid. She is said to have had three fits on the morning of the 23rd, in which she became cold and unconscious, but was not convulsed. She did not seem to have had any pain.

On admission she appeared to be well nourished, but her face was pinched and anxious-looking, and her eyes were sunken; her tongue was thickly furred; her abdomen was full, but flaccid, and free from tumour, tenderness, and pain; she had no hernia; the heart and lungs and her temperature were normal. She was admitted in the evening, and the next morning (March 25th) the following notes were taken:—"The patient slept well till 4 A.M., after which she was restless; has vomited much black grumous-looking fluid, and had some hiccough; had an enema last night, which did not act; has not rambled. She is now very

Digitized by Google

weak; still suffers from sickness, and complains of pain across the upper part of the abdomen; she looks vacant, and is fretful. Pulse 88; temperature 96·4°." Later in the day (thirty hours after admission) she passed for the first time a few ounces of urine; it was high-coloured, presented a trace of albumen and a deep indigo reaction, and its specific gravity was 1030. Her temperature at this time was normal, her pulse 90, feeble and regular, her tongue dry and thickly coated. The sickness continued.

March 26th.—Vomiting ceased at 10 P.M. yesterday; she slept till 3 A.M., after which she rambled a good deal. Now she seems feeble-minded and incapable of concentrating her thoughts or of recollecting. She complains of feeling sick, and of pain in the epigastrium on breathing deeply, and is extremely feeble. Pulse 88, weak; temperature 96·4°. A catheter was passed yesterday evening, and twenty ounces of urine were withdrawn. She died in the course of the morning. She was treated mainly with opium.

Necropsy.—On opening the abdomen, the stomach and small intestine in the greater part of its length were found moderately distended, but the last few feet of the ileum were contracted to the thickness of the little finger. The duodenum was adherent to the gall-bladder and liver in the neighbourhood. The gall-bladder itself was much contracted and difficult to make out. Its cavity communicated by an irregular orifice with the duodenum. The stomach and upper part of the bowel contained thin stercoraceous fluid. In the duodenum were two small faceted gall-stones, and one or two other similar ones were discovered lower down. Between six inches and a foot above the spot at which the contraction of the ileum commenced was a rounded gall-stone about as large as a walnut. It filled the bowel in this situation, but was not impacted in it. The intestines above the obstruction presented small areas of inflammation, as if the stone had been impacted from time to time in its course downwards, and had thus irritated the mucous membrane. The contracted portion of bowel and the large intestine contained mucus only. All the other abdominal viscera and the peritoneum were healthy. The lungs were deeply congested and œdematous. The heart was soft, and there was a good deal of atheroma of the mitral and aortic valves (which, however, were competent), and of the aorta.

The case just narrated is, I take it, a typical example of obstruction of the bowel by a large gall-stone. It is noteworthy, that (as I think usually happens in such cases) there was nothing in the previous history pointing to the passage of gall-stones; that the stone, although it had clearly caused obstruction of the bowel, was scarcely so large, one might have thought, as to forbid its ready transit and ultimate escape from the anus; that there was never any evidence—such as pain, tenderness, or distension—of the presence of abdominal inflammation; and that not only was there absence of fever, but the temperature was generally subnormal. The patient died apparently partly of asthenia and partly of collapse, determined by the concurrence of inflammation of the mucous membrane of the upper part of the small intestine, with obstruction of bowel, vomiting, and incapacity to take nourishment.

Burlington-street, W.

TRANSPLANTATION BY EXCHANGE.

BY C. B. KEETLEY, F.R.C.S.,
SENIOR SURGEON TO THE WEST LONDON HOSPITAL.

THE title of this paper is the name I would apply to an operation by which two portions of living tissue are made to exchange places. The following case will illustrate the procedure and the kind of circumstance in which it may be advantageously employed.

In March, 1886, a female infant, aged two or three weeks, was brought by a neighbour of its mother's to the West London Hospital with a request that a hairy mole covering nearly the whole of the left cheek might be removed. I explained that the result would be a contracting scar worse than the mole, and sent the child away. Next week the neighbour returned, and said that the mother could not endure the sight of the large mole, and would prefer a scar. I placed the infant's arm against its face, and was rather dismayed to see that all the skin of the outer side of the upper arm, from the shoulder down to the elbow, would be required to replace the mole should I cut away the latter and then fill in the flap by transplantation. Upon reflection, I resolved to *exchange* the hairy mole of the face and the smooth white skin of the arm. The advantages of this plan are obvious, and especially the consideration that the mole would give useful skin for the upper arm; but it will be better to defer enumeration of them till the operation and its results have been described.

On April 2nd, the little patient being anæsthetised, I first thoroughly cleansed and disinfected the cheek and arm with liquid potash soap (Duncan's) and solution of perchloride of mercury, successively. Next I marked out the flaps in the following manner. A straight ink-line was drawn from A to B (see illustration). The arm was then placed in comfortable position, arching upwards over the face and head. The wet ink on the line A B printed a second line on the arm at C D. A paper pattern of the flap to be removed from the face was cut, and with its aid an exactly similar flap was marked out on the arm, so that C D H G on the arm corresponded to B A E F on the face, each letter to each respectively. Though this is a very simple matter, some care is required in practice to avoid confusion. The knives, scissors, sutures, needles, forceps, &c., to be used lay in a tray of carbolic lotion, but were dipped in boiled (not boiling) water immediately before use and replaced in the carbolic tray when not actually in use. The object of this was to take care that no erysipelas or other specific infection should be carried by the instruments, and yet to prevent the flap and raw surfaces from being irritated by the carbolic. The sponges had all

been thoroughly disinfected, although they were now placed in water only. The face flap was reflected first. It included the subcutaneous fat proper, which had to be carefully separated from the cushion of fat which swells out into the middle of the cheek from beneath the ramus of the jaw; and it was necessary also to cut very carefully and *see* everything which was divided near the parotid and some of the branches of the facial nerve. The structures in an infant's face are, of course, comparatively small and near to each other, and the amount of fat is, comparatively, very considerable. Almost all the cutting throughout the operation was done with scissors, and not very sharp ones either. The main object of this was that bleeding might stop rapidly, and thus dry surfaces be obtained speedily—a very important matter in a plastic operation. This object was entirely attained in the case I am describing. The arm flap also included the fat down to the deep fascia. As I thought it would be somewhat difficult to put in the sutures when the arm was up against the face, I applied entirely distinct, but corresponding, sutures to the arm flaps and edges of the arm wound on the one hand, and to the face flap and edges of the facial wound on the other, and afterwards lifted the arm to the head, placed the arm flap in the facial wound and the face flap (containing the mole) in the arm wound, finally using the ready-placed sutures as "tags," which, twisted together each to each, fixed everything with absolute security and accuracy. But this plan, though excellent in suitable cases, was scarcely necessary in this, and was, indeed, a little too elaborate. The angles between the arm and face, near the flaps, were now packed with iodoform gauze,

Digitized by Google

and the whole arm was most carefully fixed to the head and neck with good strapping. Finally, over sufficient flannel and wadding, the head and thorax and *both* arms were rigidly secured in plaster-of-Paris. The whole had somewhat the appearance of a large egg with an infant's face peering out of a hole near one end and its hips projecting and legs kicking freely out of the other end. The child's conduct showed that it was free not only from pain, but even from discomfort.

The following notes of the after-treatment were made by the house-surgeon, Mr. Harold Des Vœux:—April 9th (seven days after operation): Part of case removed; dressings found to be very offensive. Both flaps looking well, though the face flap is red and the stitches along its anterior border have given way. Dressed as before.—13th: Whole case removed and bases of flaps cut and sutured respectively to face and arm. This, of course, liberated the arm from the head and severed each of the two transplanted flaps from its original connexions, completing the exchange of places. At the lower and outer border the flap upon the face was found to be not adherent and partially redundant, owing to cicatricial contraction of the face wound; it was therefore pared to fit, and re-sutured to the face. Wounds dusted with iodoform; both arms strapped to body to prevent child from scratching the wounds.—20th: The face flap not fitting perfectly in one or two places, it was there refreshed, adjusted, and fixed with fine horse-hair sutures.

The result bids fair to be excellent, though not perfect, owing to the fact that a certain amount of cicatricial contraction had taken place in each wound. I feared this would pull the mouth to one side eventually; but it appears now, nine months afterwards, that this has not occurred. The following account of the present state of the case is written by Mr. C. H. Taylor, house-physician to the West London Hospital, who has just visited the little patient to report on it:—"The child is much fatter and healthier in appearance; the transplanted skin on the face is of the same colour and appearance as the rest of the face; all that is noticed is an incomplete irregular ring of depressions or dimples and linear scars, these being slightly paler in colour than the surrounding skin. At the outer and lower edge nearest the ear are two small patches of mole, one about the size of a pea and the other smaller;[1] they are pale brown in colour, and have a few silky hairs growing from them. The arm is much fatter, and the mole upon it is more raised and movable than it was upon the face, but it remains the same in size."

There can therefore be no doubt about the satisfactory results attained by this mode of operating, which is, to the best of my belief, new. It is obviously a very great advantage to be able to anchor, so to speak, the arm to the head by the strong sutures which unite the former to the transplanted mole. It is thus rendered needless to put any except fine sutures into the face. Secondly, the bases or necks of the two flaps, lying with their raw sufaces in mutual contact, help to keep up each other's warmth and nutrition. Thirdly, not only is the risk of sloughing diminished, but should the part removed from the arm slough, the mole saved from the face is there covering the arm wound with healthy and supple, though discoloured and abnormal, skin. I cannot help thinking that this plan of preserving what might be termed "healthy disfigurements" of the face, such as hairy moles, and *exchanging* them for skin taken from parts usually hidden by the clothes, to be a great improvement on the practice of excising such moles and wasting them.

[1] These small patches lay near the border of the large mole when it was transplanted, and were left behind.

SANITATION AT SHREWSBURY.—The Shrewsbury Corporation at the quarterly meeting on the 14th inst., considered reports of the borough surveyor for a new water-supply and a new drainage system which would carry the whole of the town drainage into the Severn at a point below the town. The water scheme proposed to take the water out of the river above the town, and after filtering it to pump it into a service reservoir, from which the whole of the town could be supplied by gravitation. The estimated cost was £26,000. The sewage scheme would entail, when complete, an expenditure of £16,000, but at present only £7800 of this was to be laid out. Both plans were agreed to.

MINIMA VISIBILIA AND SENSORY CIRCLES.

BY THE LATE BRIGADE SURGEON T. OUGHTON,
ARMY MEDICAL DEPARTMENT.

(*Concluded from p. 310.*)

THERE is an idea of motion when an image traverses the retinal disc of a motionless eye, or when the finger is passed over the surface of the skin; the prevalent doctrine accords the resultant perception to a consecutive excitation of impressional areas. Advantage may be taken of the present opportunity to instance a few arguments justifying the classification of apparent motion with the secondary perceptions.

1. No progressive motion is experienced in a train passing along a dark tunnel, or in a ship's cabin, because the muscular system is quiescent. But our progression when walking in the dark is quite perceptible. How is this? It cannot be due to the tactile impressions made on the feet, even granting them to be unlike, since no idea of motion is presented by a succession of dissimilar sounds, or by the different thoughts of ideation. Neither can it be explained by noting the time that it occupied in each step, since time and motion are not to be confounded (Locke). This philosopher imagines the sun to be a fire lighted in the same meridian every twenty-four hours, and asks whether such a regular appearance would not serve to measure duration as well without motion as with it. No solution is available saving that of muscle-perception.

2. Apparent motion is realised by the aid of the thaumatrope or zoetrope; but it is inconceivable (as with different sounds or thoughts) that the retinal representations of a number of successive attitudes—the consecutive phases of a horse leaping a gate, say—should generate the mental notion of a motion, inasmuch as there can be no possible relation primarily between any two such mechanical representations. Contrariwise, however, as the hand perceives an object in two positions by movement of the arm through a certain angle, so the secondary perception of the horse in one position is amalgamated with a similar perception of the horse in another position. It is the linking of these like perceptions that is essential to the idea of a perceived motion.

3. Objects are perceived to gyrate round the individuality after rapid rotation of the body, notwithstanding their retinal images are fixed. The general rotatory muscles, in this case, cause the centre of perception to spin round in one direction, whilst (by sympathetic secondary abeyance) the straight muscles of the eyeball give rise to objective gyration in the opposite direction; when walking rapidly along a road, in like manner, the adjacent hedge-rows seem to move oppositely. Here is evidence that the secondary perceptions of vision are persistent after absolute cessation of the antecedent bodily movements, and we have already employed this principle of persistence in the formation of visual angles.

4. Let a traveller by train fix his optical axes on an object some 300 yards distant, he will observe that the near hedges move rapidly in one direction, whilst the more distant trees move slowly in an opposite direction; this effect may be likened to the arms of a balance swaying horizontally about the binocular centre. It is true that the nearer objects are depicted on the upper and those more remote on the lower retinæ, but the main incident resides in the images of both sets of objects floating over the fundus in the same course; how, it may be asked, are such contradictory results to be reconciled excepting by some process of secondary perception? Whilst confessing that the paradox awaits a definite solution, I cannot omit to note its striking analogy to the twofold forms of monocular relievo, wherein a superficial extension is seen to face towards the right under one form and towards the left under the other form (conversion of phase).

Resuming our data, when the points of a pair of compasses are applied to the skin of a blindfold person, they require to be separated by a certain interval—the diameter of a sensory circle (Ernst Weber)—before they can be identified as being duplicate. Apparent number, consequently, has been viewed as resulting from the intervention of one or more sensory circles or retinal cones; but our proposition makes it to consist in the appreciation of two or more distinct directions, and the phenomena of single and double vision or

Digitized by Google

touch (already cited) are a sufficient illustration. Number, indeed, is related to two classes of perceptions entirely distinct; it is a secondary perception in connexion with extension and form, and primary in its relation to time—so many sounds striking the tympanum per minute. This distinction between the mental ideas of number is important, furnishing a satisfying clue to the paradoxical impossibility of squaring a circle; thus, a ring of thread is readily convertible into the square formation (secondary), whilst the feat is impracticable by mathematics (primary); a straight line, again, is unity in a secondary aspect, but it may be abstracted into any number of primary measures (and the same for a superficies). Take another example of number: a printed word appears *per se* to be a unite (secondary), although its several letters may be counted; the mental idea of number, in this instance, is *primâ facie* so many distinct volitional impacts, but it is really a question of time together with a succession of primary perceptions.

Sensory circles vary in size in different parts of the body. The adjoining table gives their apparent diameters according to different authorities:—

	Weber.	Le Conte.	Bernstein.
Tip of tongue ...	½ a line	$\frac{1}{30}$ in.	·039 in.
„ fingers ...	1 to 2 lines	$\frac{1}{16}$ to $\frac{1}{8}$ in.	·079 in.
Palm of hand ...	5 lines	¼ in.	—
Back „ ...	14 „	⅛ to ¼ in.	·157 to ·196 in.
Arm	30 „	⅛ to ¼ in.	—
Back	30 „	3 in.	1·97 to 2·36 in.

Fineness of tact conjoined with correspondent mobility in various parts has long been recognised, as in the elephant's trunk, the beaver's tail, &c.; such a constant ratio between sensory and muscular acuity (well shown by the table) has been viewed in the light of a mere coincidence; but it is offered as verifying a motor causation. The dimensions of sensory circles have been attributed to textural fineness of nervous organisation; thus, if we suppose one hundred tactile papillæ to exist in a circle of the back (3 in. diameter), there will be a like number in a circle of the palm of the hand (½ in. diameter), whereby the hand's sensibility is so many times greater than that of the back. But, by the proposition, the cutaneous nerve-expansion may be universally equisensitive in so far as the present phenomena are concerned; and what are the practical facts concerning increments of sensibility? I consider that sensibility is best measured directly by passing the forefinger lightly over different surfaces of the skin. If we adopt this method, a tolerable equality of sensation will be felt between the palmar aspect of the forearm and hand; these surfaces appear to be more sensitive than that of the forefinger, whilst the back and flanks are highly sensitive. Then, touching another point, it has been assumed that one hundred cutaneous corpuscles in a sensory circle really signifies a corresponding number of fibrillary terminations in the brain; how is the single impression disposed of? Mental essence, according to the *adhuc* highly mechanical but rather speculative neurologists, now steps in with its stately faculty to charm away every dilemma; the mind, it is said, whilst it can readily identify each fibrillary stimulation, is limited in its differentiation of an aggregation of impressions unless more than a certain number (a hundred say) of fibrillary insertions are excited. I am not aware that it has been decided whether or not the fibrillary insertions are more compressed in some cerebral areas than others; but here, in the absence of an explanatory *modus*, I contend that the foregoing hypothesis is foundered. Truly says Locke, "In bare naked perception the mind is passive, and what it perceives it cannot avoid perceiving." In truth, physiology points everywhere to conscious mind as being an impressional resultant rather than an impressional generator or modifier.

Proceeding next to examine a few data which seem to be intelligible only on the terms of the proposition, the first remark is that the minimal visual angle of 44″ is an invariable value in every part, lateral or direct, of the retina. On the terms of Le Conte, however, (1) that the size of the cones determines the minimum visibile, and (2) that the cones of the macula lutea are far smaller and more numerous than elsewhere, it will result that minimal angles are more acute in the axis, rather than that a hyperæsthesia ensues. Sensory circles are of variable, and visual angles of uniform, value; in the latter case, because ocular rotations affect equally the entire retinal expansion.

The following facts, lastly, refer especially to the tactile faculty, and possess a marked significance: — (*a*) Sensory circles differ in size in different individuals, well shown in the above table. Does a more close disposition of nervelets in some persons offer a satisfactory reason for the difference? (*b*) They differ in size in the same person at different times. Has the mind an influence to contract or dilate cerebral impressional areas, and irrespectively of volition? (*c*) They are developed by assiduous exercise—e.g., the blind man reading with his fingers, or the armless woman sewing with her toes; the sensibility in these cases is increased in an equal ratio with the mobility. Is this a mere coincidence? Let us draw a simple parallelism in reply to these queries. Thus: Some persons play billiards better than others; they are in a better cue for play at some times than others; they profit by practice. Well, then, has primary sensation any causative bearing on either parallel?

Addendum.—At the close of a protracted investigation concerning the nature and various phases of the secondary perceptions, comprising several memoirs which have been honoured by insertion in these columns, I may be permitted to add a few general remarks. My hypotheses on erect and single vision, visual reliefs, &c., have been present to my mind in a more or less imperfect shape for upwards of a score of years. These several subjects tend to elucidate, and have been elucidated by, what a strict inductive system seems to justify me in styling a theory of secondary or acquired perception. The main feature of the theory consists in a brainward transmission of the *vis insita* of voluntary muscular tension, to enter into a combination therein with relational centripetal currents of primary perception for the evolution of appropriate forms of secondary perception—that is, for the mental declaration of the primary qualities existing in natural bodies. I am happy to say that the theory does not seem to be invalidated by, but rather harmonises with, the experimental researches of Professor Ferrier on the motor areas of the cortex. Professor Wyld states for instance, in reference to the faradisation of the anterior lobes giving rise to contractions of the head and limbs of animals, that he is not disposed to surrender his admiration of the forehead as the seat of intelligence; I cannot subscribe to his position, however, seeing that by far the major part of intellectualism is a motor process. The following remarks of Dr. James Davey bear directly on the context, and I cordially endorse them. He writes: "The application of stimuli to portions of the cerebral surface beget, as a matter of necessity, certain and defined muscular movements; but such are no kind of proof that a centre or source of mere motive power has been reached or excited to action. The movements observed are, to all intents and purposes, due to another cause, and that a psychical or mental one."[1] Then he points out that this must be so, since the stimuli may produce like motor results indirectly through the instrumentality of one or more of the external senses—the sense of sight, or touch, or sound, and so on.

One or two words more. The muscle sense of Sir Charles Bell has especial reference to a recognition of the position of the limbs and other movable parts of the body, together with sensations of solidity or impenetrability (not solid form), the weight and other resisting properties of essences; hence it is a line of research having only a remote connexion with the various doctrines enunciated in these columns. It might repay investigation to trace the reason that a Chinese or Japanese painting exhibits such vivid colouration, whilst their crude notions of perspective clearly evince a defective or modified secondary perception; their statuettes, too, are such grotesque contortions. Is it dependent on their sedentary habits co-operating with a perfunctory exercise of secondary attention, or are their muscular dispositions irregular? Not the least claim of the above theory is that it establishes a sound substantive basis for positive or realistic metaphysics; its obvious tendency is to deal a heavy blow to every ideational and intuitional form of philosophy as touching initial conscious states.

THE SANITARY ASSURANCE ASSOCIATION. — The sixth annual meeting of the members of this Association was held on the 14th inst., Sir Joseph Fayrer in the chair. Mr. Joseph Hadley, secretary, read the annual report, from which it appeared that the business of the Association during 1886 had been much greater than in any previous year, the income having been £804, as against £462 in 1885.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SUBMAXILLARY CALCULUS.

BY COLLIS BARRY, L.K.Q.C.P.I., M.R.C.S.

THE following case is worthy of record on account of the unusual size of the calculus and the gravity of the symptoms resulting from its presence.

R. W——, aged sixty-six, consulted me early in September last concerning a swelling beneath the lower jaw on the right side, which caused him extreme difficulty in swallowing. Flashing pains came on at intervals, and extended radially from the swelling upwards into the face and head, inwards towards the tongue, and downwards as far as the right shoulder and arm. These symptoms had existed for about eight months, becoming gradually more severe; latterly the patient had begun to lose flesh, and his friends became alarmed at his condition.

Upon examination I found a hard substance corresponding in position with the submaxillary gland placed just below the ramus of the inferior maxilla, rounded in form, and more easily distinguishable from the outer side than from the interior of the mouth, and about the size of a small walnut. By pressure from the outside a few drops of purulent discharge appeared at the orifice of Wharton's duct. There was no hardness or concretion at the mouth of the duct, as usually met with in cases of salivary calculus, and there was no induration of the cervical glands. Taking into consideration the gravity of the symptoms and the increasing loss of strength, I suggested early removal, but requested a consultation. Dr. Ainsley of Hartlepool saw the case with me and confirmed my suggestion. On Oct. 12th, chloroform being administered by Dr. Ainsley, I proceeded to cut down upon the submaxillary gland by a vertical incision about a quarter of an inch anterior to the facial artery as it crosses the inferior maxilla, extending downwards about two inches; a second cross incision was made to make room. There was considerable hæmorrhage from the submaxillary and other small branches of the facial. The whole of the gland superficial to the mylo-hyoid was removed, and the calculus could then be distinctly felt at the commencement of the duct, and apparently embedded in the gland. A few of the posterior fibres of the mylo-hyoid were divided, and the calculus seized with vulsellum forceps and removed. Upon examination after removal, the calculus proved to be phosphatic, and measured one inch by half an inch approximately (the exact measurement in length being uncertain, owing to the crumbling of a portion of the calculus beneath the vulsellum forceps). The wound was plugged with lint soaked in turpentine, eucalyptus ointment and iodoform being substituted upon the following day. The subsequent history of the case was one of uninterrupted recovery, the wound granulating freely and becoming entirely healed in three weeks from the date of operation, all the symptoms previously complained of having entirely disappeared.

Remarks.—The ordinary method of removal by incision of the mucous membrane was impracticable in this case owing to the depth of the calculus from the surface of the mucous membrane. Erichsen mentions, as the largest calculus removed, one of the size of a small damson-stone; but, so far as I can ascertain, no mention has been made of a calculus of this size occupying so deep a position.

Castle Eden, Durham.

ERUPTIVE ECCENTRICITIES.

BY J. G. MARSHALL, M.B. CANTAB.

MRS. Q——, aged forty-eight, married, living alone, had been a sufferer from chronic rheumatism for several years. She had an attack of facial erysipelas some time back, but could not fix the date. She was subject to occasional severe attacks of neuralgia, for which I could find no visible cause. About two months ago she presented the symptoms of erythema nodosum, and went through the illness in a severe and typical form, the patches being very large and painful, leaving the shins, back of forearms, and inside of thighs covered with livid marks, as if she had undergone a beating. At the end of a fortnight this eruption seemed to have run its course; but the patient still seemed very unwell, and complained of stiffness about the neck and jaws, with continual pain in the head. She maintained that she had been suffering from erysipelas, though she acknowledged that she had not been like it before. Two days after the last crop of erythematous lumps had disappeared she was seized with erysipelas of the head and face, and had it very severely, with high fever and extensive swelling of the face and neck.

She was for two or three days in a very critical condition, the features being almost obliterated, and the infiltration of the tissues of the neck deep and extensive. One morning when she was getting better she complained of intense itching of the back of the forearms and hands, which on examination presented the unmistakable white "wheals" of urticaria. There was little or no redness of the skin; the eruption was confined to the extensor surface, did not reach above the elbow, and died away in forty-eight hours. There had not been a trace of erysipelatous rash on the body during the attack of that disorder. A short time ago I congratulated her on getting on so well, when she said that she had another attack of erysipelas at the bend of the elbow. On examination of each elbow-joint, on the flexor side, and nowhere else, I found a patch of typical eczema, the vesicles being perfectly unmistakable, with watery exudation and shiny redness. She had been scratching with her nails, which she had not done before. Fresh patches of eruption appeared at the wrist. Both yielded readily to treatment, and now nothing is left but a little branny desquamation.

The case is such a remarkable one that I think it deserves publication. I have not the smallest doubt as to the several characters of the eruptions, which I observed most carefully. Unfortunately I am at a disadvantage in being at a distance from any of my own profession, or I should have exhibited the case. I am quite prepared to see this lady shortly with a fine development of herpes zoster, or exhibiting patches of psoriasis to complete the series. She is of a highly nervous temperament, and occasionally subject to fits of great excitability.

St. Margaret's Bay, Dover.

THE TREATMENT OF MALARIAL DISEASES BY PICRATE OF AMMONIA.

BY H. MARTYN CLARK, M.B., C.M. EDIN.,
IN CHARGE OF THE AMRITSAR MEDICAL MISSION.

PICRATE OF AMMONIA possesses valuable therapeutical properties, though it does not seem to have received the attention which it deserves. The characters, properties, and uses of this substance were carefully investigated by Dr. Dujardin-Beaumetz, and the results were communicated by him to the Therapeutical Society of Paris in 1872.[1] The salt had previously been successfully used in the treatment of intermittent fever by Drs. Braconnot, Calvert, Aspland, Bell, and others. Dr. Beaumetz's investigations confirmed the results at which these observers had arrived, and showed that in this substance we have a valuable, and efficient substitute for quinine in the treatment of malarial diseases. It appears to have passed out of mind, and, as far as I can gather, has never been used in India. My attention was directed to it accidentally in the following way. I had a patient under my care at a hill sanatorium who had suffered for seven months from severe intermittent fever of the quotidian type. Quinine, arsenic, and other antiperiodics had been, and were, freely used, but failed to give relief. After ten days' treatment the fever still recurred daily with its accustomed severity. At this juncture the local chemist told me of a remedy for fever, which he had received some years previously, but had never tried. This I found to be picrate of ammonia. I gave it to my patient, with very gratifying results. The fever did not recur next day, nor did it do so at any time during the three subsequent months in which she remained under my observation. I have since then constantly used the picrate of ammonia in the treatment of malarial diseases. There has been ample opportunity to test it fully, for Amritsar is notorious in the Punjab for its unhealthiness, and diseases of this kind are severe and frequent. During a period of four years and a half, I have treated over

[1] THE LANCET, Oct. 12th, 1872.

Digitized by Google

10,000 cases of these diseases with this agent, with the happiest results. So uniformly successful has it been that I have in our very extensive practice here, given up the use of quinine and the cinchona alkaloids for the treatment of intermittent fever, and have substituted picrate of ammonia for them. A record was kept of 5000 cases of intermittent fever treated with this agent. Of this number, in nine cases only did it fail to cure, and in these quinine succeeded at once. I usually give it in doses of from one-eighth of a grain to a grain and a half four or five times a day in pill. Half a grain is a fair average dose. Thus given the result is soon visible. In the great majority of the cases treated, half-grain doses in the interval prevented the recurrence of the next attack of the fever, while in about 20 per cent. of the patients two or three attacks followed before the fever ceased. In one case of quartan ague, despite large doses of the salt, the fever recurred for six periods, gradually diminishing in intensity, and then yielded to it. It is equally successful in all the forms of ague, but it is a curious fact that the cases in which it failed to cure were all of the tertian variety. I have also employed this agent in the treatment of twenty-five cases of malarial neuralgia of various nerves, six cases of malarial headache, and one of malarial colic. In all these instances it cured completely and speedily. In remittent fever it does not appear to be of use; six cases of a severe type were treated with it without any effect. Neither is the enlarged spleen of ague benefited by it. I have given it in numbers of such cases in conjunction with ergotine with good results, but such results are secured equally by the use of the ergotine alone.

My experience leads me to the conclusion that in all varieties of intermittent fever, and in malarial neuralgias, picrate of ammonia is a valuable antiperiodic, and it is an efficient and perfect substitute for quinia. It has the following advantages over quinine:—1. It is much less expensive. This is an important consideration where, as in Indian practice, hundreds of cases of malarial diseases have to be treated annually. 2. The dose given is very much smaller. 3. It does not produce the unpleasant effects that quinine does—headache, deafness, tinnitus, &c.; nor does it disorder the digestion or cause nausea, as quinine is apt to do, in the doses in which it has to be given in India.

Amritsar, Punjab, Northern India.

CASE OF TRAUMATIC TETANUS; RECOVERY.

By JOHN WELPTON, L.R.C.P.L., M.R.C.S.

IN THE LANCET for 1886 two cases of recovery from tetanus (traumatic) are referred to. I had myself a short time ago a successful case.

On Sunday evening, Nov. 7th, I was called to B. B——, a tall powerful man about the age of thirty, and found him suffering from pronounced tetanus, with eyes fixed and staring, hands clasped behind the neck and quite rigid, and opisthotonus so strong that four people could with difficulty keep him down when the spasms were violent, those of the diaphragm being agonising. I placed him under the influence of chloroform, and administered within a short time two drachms of bromide of potassium, together with one drachm of chloral hydrate. I remained with him nearly three hours, when he became quieter and had no more spasms. He was quite well in two or three days. His friends did not know of any wound, but the man explained that in cutting a corn under the right great toe he had cut painfully into the quick three or four days ago. He was a night watchman at that time and much exposed to the weather.

Ravensthorpe, Yorks.

CASE OF MELANOTIC SARCOMA.

By J. N. BREDIN, L.K.Q.C.P.I., &c.

THE patient, a lady, aged fifty-four, first noticed a little spot on the right heel about the last week in October, 1886, thinking it was merely a chilblain or occasioned by a tight boot; it gradually, however, became troublesome, though entirely free from pain, and she then consulted my predecessor Mr. Holt, who advised a consultation. Accordingly, Mr. Rivington was called in, and advised an operation which was performed on Nov. 29th, and seemed effectually to remove the mass. I saw the patient on Dec. 2nd. The growth had none of the characters whatever of melanosis—in fact, up to this time nothing showed itself from October to lead one to be certain. Meanwhile, Mr. Holt and Mr. Rivington suspected melanotic sarcoma. About eight days after the operation several spots of unmistakable melanosis appeared, first on the outside and subsequently on the inside of the thigh, and afterwards on the heel, and was now covering the cicatrix of the wound, which healed without intermission. All these places on the thigh and heel are now becoming confluent and extending and growing rapidly on the skin, without pain. One spot identical in character appeared on the head, and a single one on the back. Neither of these has increased in size, nor have any fresh ones appeared. This is, I presume, a most interesting and remarkable case, and may be seen by any medical man who may appoint an hour with me, as the patient is most willing to be seen by anyone.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

GUY'S HOSPITAL.

SEVEN CONSECUTIVE CASES OF CHARBON TREATED SUCCESSFULLY BY EXCISION.

(Under the care of Mr. BRYANT.)

WE are able to publish a series of cases of malignant pustule which have occurred in the wards of Guy's Hospital during the course of the last few months, all of them under the care of one surgeon, and successfully treated in a similar manner, by excision, followed in some instances by the application of caustic. This disease is one of which during the last few years several examples have presented themselves in London, chiefly at Guy's and the London Hospitals, and much has been done by the surgeons of these institutions to advance our knowledge of it. The cases, two of which we give this week, will be read with interest, and the difference in the local and constitutional symptoms carefully noted.

CASE 1.—*Charbon of right temporal region, with lymphatic enlargement; excision; skin-grafting; cure.* (From notes by Messrs. Du Boulay and F. P. Sarjant.)—Chas. A——, aged twenty-nine, a labourer at a hide warehouse, was admitted on Jan. 21st, 1885. The patient's father died of aneurysm of the heart; his mother is living and well. He has been a hard worker, and steady in his habits. Had measles when a baby, and rheumatic fever when he was a boy (this lasted six weeks). About four years ago he was ruptured, and ever since has been wearing a truss. He has of late had some palpitation and nervousness. The patient, who works at a hide factory, was sent to the hospital by the manager (who, he thinks, had the disease himself some years ago). About Christmas last he came as an out-patient with a swelling like a boil on his left cheek. This was opened, and he got well. He was in his usual health up to Monday, the 19th ult., and was at his ordinary occupation, which consisted in handling hides of all kinds, which had come from all parts of the world; they were cow, ox, buffalo hides, and rabbit and opossum skins. While he was at work he felt an itching on his left temple, and putting up his hand felt a small pimple about the size of the head of a pin. He felt dull, depressed, and cold that day. On the Tuesday he still felt poorly, the pimple had increased to about the size of a pea, and the surface was black. On the Wednesday it was blacker and larger. During the whole time he had felt cold and unwell, but had kept at work until he was admitted into hospital.

Condition on admission.—The patient is a well-built, healthy-looking young man. When placed in bed he shivered and complained of bad headache. Temperature

Digitized by Google

99·8°; respiration 20; pulse 88. The pustule was situated on the left temple, about an inch behind the outside of the eyebrow and above the zygoma. The central slough measured one-eighth of an inch in diameter, and was circular. It was surrounded by a rim of vesicles whose long diameter—namely, in the horizontal direction—was three-eighths of an inch; in their short diameter—the vertical—a quarter of an inch. The vesicles were more marked above, and at the back there was redness of the skin for about two inches and a half from above downwards, which faded away gradually; the pustule was not raised above the skin more than one-sixth of an inch. The glands at the angles of the jaw were enlarged on both sides, particularly on the left. His teeth were bad. There was a swelling on the left side of the face just below the angle of the mouth. There was also a pimple on the left side of the back of the neck, about the size of a pea, red like a boil, without perceptible black centre. The patient was unable to open his mouth very widely.

At about 7 P.M. on the day of the man's admission, Mr. Du Boulay, by Mr. Bryant's instructions, removed the pustule. Chloroform was administered in the ward. A skin incision, elliptical in shape, was made behind the eyebrow to about half an inch in front of the ear, extending in depth to the deep fascia over the zygoma. The skin and tissues beneath, between the incisions, having been dissected away, the raw surface was thoroughly cauterised all over with Paquelin's thermo-cautery; the wound was then dressed with terebene oil and a pad of lint bandaged over it. The patient took chloroform very well, and was not sick after it. He was ordered five grains of sulphate of quinine every four hours, four ounces of brandy, and full diet.

Jan. 22nd.—The patient was restless during the night, as he said, from headache and the effects of chloroform. Temperature 97·2°. He seemed fairly comfortable. His bowels were open twice yesterday before his admission. Urine limpid, clear, and of a light straw colour, much lighter than normal. Sp. gr. 1017; slightly alkaline reaction; no albumen, mucus, blood, or pus; on boiling there was a slight whitish precipitate, which disappeared on the addition of nitric acid. At 2 P.M. the patient was much the same; his face was red and puffy, and he had headache, and a singing or buzzing noise in his head. Wound painful. Evening temperature 98·8°. Wound dressed. No bacilli could be detected in the urine.

23rd.—The patient passed a good night and feels comfortable. He is better than yesterday. The pimple on the back of the neck is not a charbon. There has been no rise of temperature.

24th.—The patient feels only a little soreness about the wound; slight headache. His bowels have not been open since his admission. Urine of normal colour; sp. gr. 1024; no albumen, but some phosphates; slight acid reaction; no bacilli could be detected, although the examination was carefully made.

25th.—The patient passed a fair night. Complains of increased soreness in the wound and shooting pains across the back. In the evening he seemed worse. Temperature 102·5°. The quinine was omitted, and ten grains of calomel and colocynth given at night; also twenty grains of salicylate of soda in orange flower water every three hours.

26th.—Passed a restless night; has great pain in the head and across the back and chest; temperature 99·2°; bowels open. Pulse 84; respiration 20. Urine: sp. gr. 1025; normal colour; no albumen; could find no bacilli.

27th.—Bowels open this morning. Not much alteration in patient's condition.

28th.—Passed a good night. Great soreness in the wound. Patient says he feels better. Pulse 72. Wound dressed in the evening.

30th.—Patient doing fairly well; bowels open daily. The wound itches and smarts very much.

31st.—The salicylate of soda ordered three times a day. Patient much the same; takes his food well. Urine straw-coloured; acid; no albumen; sp. gr. 1021; reaction of salicine.

Feb. 9th.—Has been getting up daily since the 4th, and is making good progress; there is still a quantity of discharge from the wound. Patient feels fairly well in himself. Ordered fifteen minims of tincture of perchloride of iron three times a day, with glycerine and chloroform water.

10th.—Five pieces of skin were grafted.

12th.—Three of the above have taken; the skin looks healthy, and less flabby than it was some days ago.

15th.—Three more pieces of skin were grafted to-day and the wound dressed; the skin is beginning to spread over the upper edge of the wound. Ordered a mixture, with cinchona as a tonic.

24th.—Patient progresses but slowly. The sore is not much smaller than it was on the 15th; it looks rather pale and flabby.

March 14th.—The patient was discharged to-day; wound not quite healed.

CASE 2. *Charbon of face, with enlargement of lymphatic glands; excision and cautery; recovery.* (From notes by Messrs. Beard and D. T. Jones.)—J. N——, aged thirty, living at Walthamstow, was admitted on Sept. 5th. On the previous Wednesday a small lump appeared on the left cheek; it gradually increased in size. On the Friday following she called in a medical man, who told her she was suffering from blood poisoning. She had had nothing to do with cattle, and she had a baby vaccinated recently.

Condition on admission.—The pustule is half an inch in diameter, with a black depressed centre, surrounded by a ring of vesicles containing red serum. There is a brawny hardness in the surface around for the radius of one inch; there is great swelling in the submaxillary region, where the glands are enlarged and tender.

Sept. 5th.—Urine nearly colourless; no mucus; acid; sp. gr. 1005; no sugar, blood, or albumen.

6th.—Mr. Clement Lucas examined the patient, and recommended excision, which was performed this morning by Mr. Beard. Two incisions were made, one on each side of the pustule from a point about a quarter of an inch above the side of the nose down to a point at the lower margin of the inferior maxilla about an inch and a half from the median line; then, holding the skin at the upper end with a tenaculum forceps, the skin within the margins of the incisions and a quantity of muscular substance were cut away. Two vessels were twisted. The deepest incision was near the angle of the mouth, extending at this point nearly to the mucous membrane. The wound was oval in shape, three inches long by an inch and a half broad; it was cauterised by Paquelin's thermo-cautery, and left open.

7th.—The wound appears fairly healthy; the swelling in the submaxillary region has decreased in size. Patient has been ordered a mixture containing iodide of potassium. Urine of a bright yellow transparent colour, containing a small quantity of flaky mucus; reaction decidedly acid; sp. gr. 1033; no albumen or blood; five grains of sugar to the ounce.

9th.—It should have been remarked that lymph was running from the arm before the lump appeared. Patient's baby is eight months old, and is still suckling. Fresh serum was examined for anthrax bacilli, but none were found. One of the patient's breasts was beginning to get tender, and a lotion of belladonna and glycerine was applied. The urine is of a dirty yellow opaque colour, containing a large quantity of mucus, which is of a buff colour; sp. gr. 1031; acid; sugar still present.

13th.—The wound was dressed this morning. When the dressings were taken off one of the vessels began to bleed; this was at once twisted by the dresser. She is allowed to get up an hour every evening after tea.

16th.—Ordered a ten-grain aperient pill at night; middle diet.

22nd.—Patient is taking perchloride of iron and cinchona mixture. She left this afternoon. Wound smaller, and looking healthy.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

A CASE OF ACUTE MENINGITIS IN WHICH COMPLETE RECOVERY TOOK PLACE.

(Under the care of Dr. C. E. ARMAND SEMPLE.)

FOR the following account we are indebted to Mr. C. D. Green, late house-surgeon.

William C——, aged seven years, was admitted, under Dr. Semple, on May 13th, 1886. The child was said to have been quite well until May 10th (three days before admission), when, on returning from school, he vomited and complained of headache. The following day he was drowsy, and at night became delirious. The next day (May 12th) he was brought to the out-patient department; he was then somewhat drowsy and moved with difficulty; pulse 108°; temperature 101°; tongue coated and rather brown. Whilst

Digitized by Google

waiting he appeared to become unconscious for a few minutes once or twice. As there seemed some probability of the patient being in the early stage of an acute specific fever, he was not admitted. The next day (May 13th) the mother came to say he was much worse, and, she thought, dying. He was visited, and found to be in a condition of active delirium, throwing his arms about wildly, and screaming loudly "Mother, mother," although his mother was standing close to his bedside at the time. The skin was hot and dry; there was no eruption save that produced by insects, and no inflammation of throat. His removal to the hospital was directed. Both parents living and healthy; no history of phthisis in their relatives. There were three other children, two of whom are living and healthy; the third was taken ill some two weeks before the patient, and died during his (patient's) illness. The symptoms were pain in the head, vomiting, and rapid wasting. Optic neuritis was observed; the diagnosis was tubercular meningitis, but we were, unfortunately, unable to obtain a necropsy.

State on admission.—A fairly well nourished child, complaining of headache. He was in a semi-conscious condition, but could be roused when spoken to loudly. The muscles at the back of the neck were contracted and rigid; the head was retracted, and could only with difficulty be moved. Abdomen somewhat retracted; *tache cérébrale* well marked. Pupils equal and acting to light; no oculo-motor paralysis; no nystagmus. No paralysis of limbs, and no evident loss of sensation. No abnormal physical signs in chest or abdomen. Tongue covered with a brown fur and rather dry. Temperature 101°; pulse 112, regular. Urine clear; acid; no albumen. The right optic disc appeared a little blurred.

During the night the patient was wandering and noisy, frequently screaming loudly. The following day (May 14th) he complained much of headache. There had been no vomiting since admission; he answered questions and obeyed directions. The urine and fæces were passed into the bed. During the next few days the more acute symptoms subsided somewhat; the patient became conscious, and, though he still complained of headache, slept fairly well at night. (He had been kept in a dark room.) The temperature chart showed evening exacerbations, with morning remissions, but rising slightly higher on successive nights (maximum 103°). On the morning of May 20th the temperature fell to 99°, and remained below that until the evening of May 21st, when it rose suddenly to 103°. The patient was rather drowsy, and still complained of headache. He lost flesh rapidly; his weight, which on admission was 38 lb., on May 22nd had fallen to 34 lb.

During the next month the symptoms were drowsiness and indifference to what took place around him, disinclination to take food, and progressive emaciation; there were frequent complaints of headache, and occasional screams and cries of "mother," once or twice repeated; seemed only semi-conscious, and would not answer questions. Superficial reflexes exaggerated; knee reflex and ankle-clonus not obtained. Pulse variable in frequency, and at times irregular. Bowels confined. With the exception of a slight convergent squint, which was noticed the day after admission and only lasted a few days, no local paralyses were observed. Temperature below 100° from May 27th to June 15th. On June 16th the weight was 29½ lb., the patient having thus lost 8½ lb. in thirty-four days. On the morning of June 22nd the patient, for the first time since admission, had a fit, in which there was general rigidity with complete unconsciousness; he had vomited twice during the morning. On the 25th he had three similar fits, the fits lasting each about fifteen minutes. No fits occurred after this date. He was at this time very feeble and extremely emaciated; was usually in a drowsy, apathetic condition, but was occasionally noisy, constantly repeating the cry "mother." He could, however, be roused to some extent when sharply spoken to. There were occasional evening rises of temperature from June 14th to July 11th, after which the temperature remained below 100° until August 9th. The patient remained in a similar condition for about a fortnight; he was markedly emaciated, and so feeble that his death was daily expected. The malar and jaw bones were extremely prominent, and the outlines of the limb bones plainly visible. No bedsores had formed at any time (he had been kept on a water-bed). There was a purulent discharge from the right ear, which was noticed for the first time a few days after admission, and no history of its presence previous to the onset of the illness could be obtained.

July 17th.—His weight was again 29½ lb. He had not been weighed for a month, appearing too ill to be moved, but had evidently still further lost flesh during the first part of the interval. Began to take his food better.

20th.—Would answer questions, but not intelligently; vomited twice on the 21st.

27th.—No complaint of headache; no vomiting.

29th.—Vomited three times; answers questions intelligently; takes food well; does not complain of pain.

Aug. 5th.—Now considerably improved; plays with toys, and takes much more notice of his surroundings; does not complain of headache; still vomits occasionally; bowels regular; gaining flesh.

On the evening of Aug. 8th the temperature rose to 101°, and the patient again complained of headache; the discharge from the right ear, which had persisted to a slight extent since it was first noticed, increased somewhat (the ear had been syringed out twice daily with boracic acid lotion, and iodoform powder had been blown in, but no other local treatment had been adopted. On the following day the temperature fell to 99·2°, and the patient ceased to complain of headache. From this date convalescence was uninterrupted, and the patient left the hospital on Sept. 23rd. His weight was then 42½ lb.; there was no mental deficiency, and the general health was good. He was seen again at the end of a month, and appeared to have no ailment; the discharge from the ear had quite ceased; the membrana tympani was not destroyed, nor was the hearing very much impaired in that ear. There was no defect of vision.

Remarks by Dr. SEMPLE.—Cases of recovery from a severe attack of meningitis, however caused, are, I think, sufficiently uncommon to make the above case worthy of record. When the patient was first admitted, the diagnosis made was tubercular meningitis (the more so as the brother was at that time under observation, who, as mentioned in the history, died of what was believed to be tubercular meningitis), and the extreme and rapid wasting which took place was certainly in favour of tubercle; the appearance of the diarrhœa, however, suggested another explanation of the case, and the slight relapse which took place associated with an increase in the discharge from the ear, and also the fact that the patient recovered, were more compatible with its being a meningitis caused by extension from the tympanum rather than due to tubercle; it must be borne in mind, however, that there was never any swelling or tenderness over the mastoid process, that the otorrhœa completely ceased without any treatment beyond syringing out the ear and dusting in iodoform powder, and that the discharge never became offensive; moreover, it appeared after the commencement of the patient's illness, so that, although tubercular meningitis could not with certainty be diagnosed, there were some points in favour of that explanation. In THE LANCET of Jan. 8th, 1887, there is an account of a case brought by Dr. Carrington before the Pathological Society in which recovery from tubercular meningitis was inferred from post-mortem evidence. In Jaccoud's "Dictionnaire de Médecine et de Chirurgie," article Méninges, are quoted two remarkable cases of complete apparent recovery after tubercular meningitis, in which a second attack of meningitis occurred after a long interval—in one case five years, and in the other one year—after the first attack; in both cases the diagnosis was confirmed by a necropsy, but, unlike Dr. Carrington's case, the exact appearances are not described, the reference to the post-mortem examinations being as follows:—In the first case, ... "Les méninges offraient des lésions évidemment graves et fort anciennes que remontaient certainement à la première attaque"; and in the second case ..... "et mourut ..... d'une tuberculose méningée avec un fort épanchement hydrocéphalique fait dont nous pûmes nous convaincre à l'autopsie." In the same article is quoted another case more exactly bearing on Dr. Carrington's case, in which a girl aged thirteen was observed to recover from an attack of meningitis "caractérisée par les symptômes les plus classiques et survenue graduellement," and who died some years afterwards of pulmonary phthisis; no reference, however, is given to any post-mortem evidence, and the writer of the article remarks that the inference that the meningitis was of tubercular origin did not appear to him to be legitimate. I have thought the case worth quoting, however, on account of its resemblance to that brought forward by Dr. Carrington.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Discussion on Nephro-lithotomy.

AN ordinary meeting of this Society was held on the 11th inst., Dr. W. H. Broadbent, F.R.C.P., President, in the chair. The whole of the evening was occupied with an interesting discussion on Nephro-lithotomy, of which the following is a full report.

Dr. GEORGE JOHNSON said nothing could be more satisfactory than the case read at the last meeting by Mr. H. Morris. The patient had suffered for nineteen years, had had to take enormous quantities of alcohol and morphia, and yet was relieved in a short time by a simple and safe surgical procedure. He had altogether given over to surgery five cases of renal calculus, and with complete success in all the cases. Three were operated on by Mr. Knowsley Thornton, one by Mr. T. Smith, and one by Mr. Morris. One of the cases was thought by a medical man to be chronic Bright's disease, but for this opinion there was not the slightest ground; yet even after the removal of a calculus the medical practitioner remained incredulous, and hinted that the stone shown him by the patient was of fraudulent origin. The case of a little girl, eleven years of age, who suffered from pyuria and hæmaturia with renal colic in the left side was narrated. Mr. Thornton operated by the combined abdominal and lumbar method, and, strange to say, removed five stones, not from the left, but from the right kidney. Had the lumbar operation been performed this case would have been set down as a failure of renal surgery. Dr. Johnson remarked that now the physician could have recourse to other measures than lithotripsy, passage of stones *per vias naturales*, and encystment before or after suppuration, with destruction of kidney, and, looking to the serious effects and dubious prospects of success of such methods, he thought the profession and the public were to be congratulated on the new aid that was afforded by surgical interference.

Mr. KNOWSLEY THORNTON gave the history of his own practice in renal nephro-lithotomy. In 1879 or 1880 he made his first attempt at lumbar nephro-lithotomy. After making the lumbar incision a large tubercular kidney was discovered. This was drained in the loin; some relief of symptoms was obtained by the patient for a time, but suppression of urine supervened, and the patient died. The necropsy showed that both kidneys were diseased. This operation suggested the necessity for a thoroughly exact diagnosis. In future Mr. Thornton resolved to secure greater accuracy of diagnosis by an exploratory abdominal section, and if a stone were found, to make a separate clean incision in the loin for its extraction. By employing Langenbeck's incision for abdominal section, he thought it would be possible to explore the kidneys and the ureters, and thus make certain of the state of both organs as well as of the position of the stone, should one be present. It was not until the year 1883 that Mr. Thornton had the opportunity of putting these principles into practice. In December, 1883, the combined method was successfully employed upon a woman aged twenty-three, with right renal calculus. She was in a bad state of health. Her father had died of renal calculus. The combined method was practised; the abdominal incision allowed of the examination of the other kidney. The left hand was used to fix the stone in the pelvis of the kidney, whilst the right hand made a clean incision in the loin straight down on to the stone. The patient did remarkably well. The overlooking a stone was illustrated by the third case, which was performed in February, 1884. This was a lumbar operation. A second smaller stone, situated higher up in one of the calyces, was overlooked. Drainage was practised, and gave some relief for a time, but suppression of urine followed. The other kidney was of considerable size. In April and in June, 1884, Mr. Thornton had two successful cases of nephro-lithotomy by the lumbar incision. In the first case the incision healed rapidly; in the second the healing was slow, and the sinus frequently reopened, but eventually the case got well. The fourth case was that of a French woman, aged fifty-nine, who was in a bad state of health. Mr. Thornton returned to the combined method in this case. But death occurred with suppression of urine in less than twenty-four hours. The fatal result was largely to be attributed to the exhausted state of the patient. She had taken a considerable quantity of morphia; the operation was prolonged; the stone was but a small one; the urine fairly healthy. The fifth case was a second operation on Case 1, reported in the *Medical Times and Gazette*. The sixth case was begun as an abdominal nephrectomy, but the kidney was found not to be removable; it contained a large stone; a counter-opening was made in the loin; the case eventually did well, though the sinus remained discharging for some time. The seventh case was that of a military officer, seen in consultation with Mr. Morrant Baker; the combined method was practised with perfect success. The other two cases were also completely successful. In discussing the general question, Mr. Thornton said that surgery should be exact. The more exact it was, the more successful would be the results. The lumbar nephro-lithotomy never will or can be exact. Surgeons have even failed by it to reach the kidney. For example, both he himself and Mr. Morris had missed the stone by this method. Though the kidney tolerated the knife, still we should all agree that it should not be needlessly incised. It was doubtful what the effect of puncturing the kidney was; punctures and incisions might lead to deleterious changes in the organ; the ultimate history of cases that had been submitted to the punctures would prove of value and interest. The more common the operation of nephro-lithotomy became, the more kidneys would be unsuccessfully explored, the greater would be the mortality, and renal surgery would lose in reputation. Mr. Thornton referred to his previous position with regard to the two operations as expressed at the Royal Medical and Chirurgical Society last session, and said he now felt disposed to go further, and to assert that the combined operation was the correct one, for we should never fail to find the kidney, never cut into a healthy one, and leave the one with the stone; never damage the peritoneum, as by puncture, without knowing it, and we could examine the other kidney and both ureters. The stone would be removed through a small clean cut in the loin, which was far preferable to the method of dissection, since this latter allowed of infiltration of tissues and favoured the chances of severe inflammation and septicity; and, finally, the combined method allowed of a thorough examination of the kidney, so that a decision could be come to which was the best operation—nephrotomy or nephrectomy—for the individual case. He said that Mr. Morris had objected to the abdominal exploration as being inefficient for perfect palpation, but his own experience did not bear out this belief. The whole investigation could be carried out with much less doubt and with greater safety for the patient, for a fairly accurate knowledge of the state of the other kidney would be ascertained. The only possible objection to the combined method was that it made two wounds; but counter openings were made everywhere in surgery, and why not in renal surgery also? The real objection was doubtless a dread of the peritoneum, but this was unfounded, and his own experience was that with strict asepticity the peritoneum tolerated operations as well as, if not better than, any other tissue of the body. Finally, Mr. Thornton made some remarks on the subject of referred pain, and said that in some of his cases the pain was referred to the other kidney, and might have led to the wrong kidney being operated on, with possible disastrous results. Ovarian pain was sometimes referred to the side opposite to that of the diseased ovary.

Mr. BERNARD PITTS briefly referred to three cases of exploration of kidney by the lumbar incision that had recently been under his care. The first was that of a woman with large suppurative scrofulous kidney; here no stone was found, but great relief was given by the drainage, and but little discomfort was occasioned from the resulting urinary fistula. In the second a stone was discovered and removed, but there was also a suppurative condition of the kidney. For one month the patient did well, but there was a constant discharge of pus from the lumbar wound, though no urine was ever detected with this discharge. This patient then suddenly developed inflammatory symptoms, and died after several weeks of continued fever; and it was found that there was a diffused suppuration behind the kidney, which extended along the aorta into the thorax. A second small stone was found embedded in the upper part of the organ. In the third case, which had been explored through the loin six weeks ago, a calculus was removed, and again a suppurative pyelitis was present. Great relief was

Digitized by Google

given by the operation in this case, but suppuration still continued, and no urine had been detected with the discharge from the loin. Mr. Pitts would like to ask those who had had experience in these cases whether one might assume that a kidney was no longer active if, after incision into its suppurating pelvis, no urine escaped at any time with the discharges. He regretted that in the second case he had not removed the organ, and so possibly saved the patient, and stated that in the last case he had felt it right to advise the man to have the kidney excised, since he believed it to be useless, and likely to continue to suppurate. Owing to the enlargement of the kidney, and to the narrowness of the interval in this case between the ribs and the crest of the ilium, it would be difficult to remove the kidney from the loin; and if the abdominal cavity was opened, it would be difficult, with the suppurating sinus present, to ensure perfect antisepsis.

Mr. MORRANT BAKER referred to a case, which he showed as a living specimen, of a young man aged twenty-three who had suffered from hydro-nephrosis for some years before 1881, when the large cyst was opened and drained. The patient was subsequently shown at the International Medical Congress, at which time he was wearing, slung to his side, a leathern bottle, into which several ounces of urine were discharged daily. Subsequently his health began to fail, and in Dec. 1882 the kidney was removed; the large cyst, the boundaries of which were beyond the reach, not only of the finger, but of a long metal sound, was left, Mr. Morrant Baker thinking that any attempt at its removal in its suppurating and probably adherent condition might involve wide exposure of the peritoneal cavity, and be very perilous. He thought, also, that the removal of the secreting organ might lead in time to withering of what would become a useless receptacle. The patient recovered well from the operation of nephrectomy, and the ultimate result justified the plan adopted, for in about two years after the nephrectomy the cyst had contracted to about the size of an orange, and was found filled by a quantity of offensive putty-like material, the removal of which with free drainage was followed by complete recovery.

Mr. GODLEE said that although he was not much enamoured of the so-called combined operation, and not eager to perform it, he thought it only right to mention two cases which might be adduced as favouring the position held by Mr. Thornton. The first of these cases was that of a young man, who had come from South Africa for the relief of most urgent symptoms pointing to stone in the right kidney, and was under the care of Mr. Marcus Beck at University College Hospital. Mr. Beck exposed the kidney fully and punctured it freely with needles, but detected no stone. The wound closed readily and rapidly, but the patient was unrelieved. Afterwards he came under Mr. Godlee's care, and the kidney was again exposed, incised, and carefully explored with the finger, but no stone was found. A few days later this patient passed a small stone. It was conceivable, though not certain by any means, that, through an abdominal incision this stone might have been detected in the opposite kidney, supposing it possible, as Mr. Thornton suggested, that a stone in one kidney may cause colic on the opposite side. He observed, in passing, that considerable fibrous thickening around the kidney had resulted from the first operation. The second case was that of a young man who had a stone impacted in the right ureter, which led to disorganisation of the kidney. An abscess formed around this kidney, which was opened; but at the operation it was impossible to discover the kidney itself. Some months afterwards the patient died of suppression of urine, coming on during one of his frequent attacks of colic, and no doubt partly caused by the opium taken to relieve the pain. Even at the post-mortem the kidney could hardly be detected, as it was reduced to a flabby bag of pus. The other kidney was enlarged and fairly healthy. Here, again, it was possible that an abdominal incision might have resulted in the discovery of the stone in the ureter, and thus have led to an incision being made into the suppurating kidney, and the evacuation of the pus might conceivably have again started the secreting action of the sound organ. On the other hand, there appeared to be objections to the abdominal incision, besides the one on which Mr. Thornton had specially dwelt. To begin with, a danger to which he had alluded was a very distinct one—viz., that of causing a ventral hernia by incising the tight muscular abdominal wall of a strong man. But, besides this, it was possible that whilst a number of stones might be cleared out of a kidney which were causing no symptoms, a small one might escape the detection even of the experienced hand in the opposite kidney, which, after all, had been the cause of the colic; and, lastly, it was surely possible, if a stone can escape detection through a lumbar incision, when the organ can be felt above and below, and behind as well as in front, it might fail to be detected when the finger can only reach the anterior aspect. A case to illustrate this position was then detailed, in which a patient had for years suffered from symptoms referred to the bladder, which at last gave way to those of marked right renal colic. Mr. Godlee cut down on the right kidney, which was quite imperceptible on abdominal palpation, and found it lying very high up under the ribs. A stone of the size and shape of a tiger's claw was found quite at the back of the gland, and it was held that this would in all probability have been quite imperceptible on feeling the organ through an abdominal incision. He maintained that it was almost certain that the abdominal method would occasionally fail when the fact was borne in mind that the most urgent renal symptoms may be caused by stones of very minute size.

Mr. BRUCE CLARKE related a case bearing on the diagnosis of renal calculus. For one year the man had suffered from occasional attacks of left renal colic, and just before admission to the hospital had a typical attack, in which pains radiated along all the branches of the left lumbar plexus. Fortunately, before thinking of an operation, the tortuous state of the arteries was observed, and a considerable pulsation was noticed in the abdomen. Abdominal aneurysm was diagnosed, and at the necropsy it was found that the aneurysm had burst into the left psoas muscle and dissected out all the branches of the lumbar plexus of nerves. Death had resulted from rupture of the dilated aorta into the pleura. A second case was related as tending to show the value of an abdominal incision with preliminary exploration. The patient had passed several stones. A lumbar incision was made, but an hour elapsed before the kidney could be found. The patient was greatly wasted and cachectic. It would have been wiser to perform the abdominal operation. A small amount of calculous matter escaped from the lumbar incision. Death followed in three days from anuria. At the necropsy fatty and amyloid degeneration of all the viscera was observed, and many disseminated stones were found in the kidney, but no distinct calculous mass. It would have been more satisfactory if the whole kidney had been removed at an earlier period.

Dr. BURNEY YEO asked the surgeons to answer the question, what were the precise indications for physicians to give up their own "unprecise" method and take to the precise method of surgery. He was not so fond of precision as to be enamoured of it. At Contrexéville patients were known to pass large numbers of calculi under the treatment pursued there. This treatment consisted largely of free drinking of the waters, some patients taking as much as six quarts of water a day.

Mr. PEARCE GOULD mentioned the case of a woman, forty years of age, from whom he removed a renal calculus last November. The history was that fifteen years before she had struck the right loin, the blow being followed by hæmaturia lasting a week. Ever since that she had had recurring attacks of renal pain, and for five years had been conscious of a swelling in the loin. When admitted to Middlesex Hospital she presented a fluctuating renal tumour in the right loin, with pyuria. The kidney was opened by the lumbar incision, and in the distended pelvis of the kidney an oval uric acid stone was found and removed. After three days urine ceased to flow through the loin, and within a month the wound was all firmly healed. The patient was shown before the meeting. Mr. Gould referred to the statistics given by Dr. Brodeur in his work on the Surgery of the Kidney. He had found 25 cases of nephro-lithotomy for simple renal calculus, with 2 deaths—the cases of Durham and of Bennett May; 66 cases of calculous pyelitis had been submitted to operation; in 44 of these nephrectomy had been performed, 34 by the lumbar incision, with 19 recoveries, 10 by the abdominal incision, with 5 recoveries; 16 had been treated by nephro-lithotomy, 13 by the lumbar incision, with 6 recoveries, 3 by the abdominal incision, all fatal; 6 had been treated by nephrotomy, only 4 of which had recovered. These statistics, like others, were not complete, as many cases had not been recorded; but they were the most recent and the most important that had been compiled. He referred to the fact that many cases had occurred where the

Digitized by Google

diagnosis of renal calculus had been made by competent observers, and on exploring the kidney no stone was detected, but the operation was followed by complete relief of the symptoms. Two such cases had occurred in his own practice. On the other hand, all must have met with cases of renal calculus which had not given rise to any symptoms during life. In reference to the abdominal operation, he thought Mr. Thornton was disposed to regard too lightly the importance of opening the peritoneal cavity, and his assertion of the tolerance of the peritoneum to operation, provided the wound was kept aseptic, applied equally to all other tissues.

DR. S. COUPLAND thought that the method of treatment known as lithontripsy might have to be practised for months and years before any appreciable effect would be made on the size of the stones, and during all this period the patient might have to suffer from severe symptoms, whilst the kidney would be injured by the presence of the foreign body or bodies. Post-mortem experience showed how injurious the effect of stones in the kidney could be. He considered that the remarkable success of surgery of the kidney ought to encourage physicians and patients alike to resort to the simple surgical method of removal as infinitely preferable to the slow, uncertain, and possibly perilous methods of medicine.

Mr. T. SMITH thought it was easy to generalise too positively, and to regard certain methods of operation as infallible in ascertaining whether there was a stone. If it were Mr. Thornton's contention that by the combined method it would be impossible to overlook a stone, he could not concur; for he knew of cases in which most careful palpation of the kidney, and even pressing it against a solid table, was unable to diagnose the presence of a stone in the removed organ. It was possible, also, that the peritoneum would not behave with equal benignity to all surgeons as it did to Mr. Thornton. He thought that Dr. Coupland took too gloomy a view of the patient's condition in cases of renal calculus. At Contrexéville, as Dr. Yeo had related, patients passed stones and led comfortable lives—nay, even lived to form other stones. A kidney that had once formed a stone was very likely to form another, thus requiring repeated operation. A three weeks' course at Contrexéville might effect wonders for the patient. He had no objection to perform the operation of nephro-lithotony; in fact, was yearning to do it. But having three near relatives suffering from renal calculi, and knowing that they had passed several stones and yet lived a fairly happy life—one relative was so little injured in general health as to be able to ride forty miles on a tricycle,—he should hesitate to resort to surgery when such simple means as abundant drinking of water would effect so much relief. One of his relatives drank six pints of warm water every day, and described the effect of drinking it as refreshing and exhilarating. This patient had had plugging of the common iliac vein, and an abscess had burst into the intestine. Yet he now led a comfortable existence. As to the water, the only precaution to observe with regard to it was that it should be drunk whilst it was very hot, and on an empty stomach.

Mr. K. THORNTON believed that it would be easier to detect a stone in a living kidney than in one that was removed from the body, and in which the circulation had ceased.

Mr. HENRY MORRIS said that in the five minutes at his disposal it would be impossible to reply adequately to all the observations that had been made, so he should confine his remarks to the question of the relative merits of the lumbar and abdominal methods and to the point raised by Dr. Burney Yeo. As to Mr. Thornton's objections to the lumbar nephrotomy, he admitted that some of the objections might hold good, but contended that even by the combined method the stone could not be located with certainty, and that, indeed, there was nothing very advantageous that could be claimed for the abdominal incision. The lumbar wound might heal as rapidly as possible, so that he could not concur in Mr. Thornton's remarks about the necessarily slow healing of this wound. He illustrated the rapid healing of the lumbar wound by reference to cases that had been under his care. The freedom from fatality and misfortune, the absence of any difficulty in finding the kidney, and the ease with which the various surfaces of the kidney could be palpated were some of the advantages of the lumbar operation. What was wanted was greater precision in diagnosis, and he suspected that some cases of failure to find the stone might be attributed to this want. When the kidney was thought to be the seat of mischief, in cases of pain resembling renal colic, he thought that the directing of the attention to the prostate in the male, and to the ovary and Fallopian tubes in the female, would lessen the chances of making an erroneous diagnosis. The more accurate the diagnosis, the fewer would be the failures to find the stone. In answer to Dr. Yeo, he would say that when the Contrexéville and water-drinking treatment had been tried and the patient still possessed the symptoms of stone, then the physician might reasonably, and without fear or trembling, call in the surgeon, who would in a short space of time effect far more for the benefit of the patient than would any amount of water.

Mr. BENNETT remarked that the direct sounding of the kidney by freely puncturing the organ was a frequent practice at St. George's Hospital, and the results of this practice were most encouraging.

Mr. Howard Marsh did not reply owing to the lateness of the hour.

The following living specimens were shown:—Dr. A. H. Robinson: Case of (?) Congenital Cretinism and Myxœdema in a man aged twenty-three. Mr. H. H. Clutton showed a case of Lupus with Ulceration of Palate and Phthisis, and a second case of Tubercular Ulceration of Palate. Mr. H. Morris: A successful case of Nephro-lithotomy. Mr. Battle, for Mr. Sydney Jones: A case of Rheumatoid Arthritis in a girl aged six. Sir Dyce Duckworth: A case of Heart Disease with Rheumatic Nodules.

MEDICAL SOCIETY OF LONDON.

Removal of both Superior Maxillæ.

AN ordinary meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Dr. LEOPOLD SERVAIS (of Antwerp) read a paper on Removal of both Superior Maxillæ for large tumours of the face. The first case was that of a boy aged nine years, living at Wouroo, Holland. The operation was performed on Oct. 10th, 1883. The tumour had developed at the expense chiefly of the right superior maxilla. Fergusson's method of operation was adopted. The cautery was used to stanch the bleeding. The roof of the orbit, the orbital plate, the nasal process of the right superior maxillary bone, and the larger part of the malar bone were preserved. Recovery was rapid. There has been no recurrence. The second case was that of a woman. The tumour had been slowly growing for eleven years; it was of enormous size and extremely painful. It had been treated by caustics. The tumour was successfully removed, and the patient was now completely well. The operation took five hours.

Mr. F. BOWREMAN JESSETT read a case of Sarcoma involving both superior maxillary bones and hard palate, with removal of the tumour, together with great part of both bones, ending in recovery. The patient was a woman, aged thirty-five. She first noticed a lump in the hard palate twenty-one months ago; it grew rapidly, and projected considerably into the mouth and interfered with eating and speaking. At the end of six months she went to Guy's Hospital, under the care of Mr. Lucas, when the tumour —a myeloid sarcoma—was excised, and its base scraped and cauterised. In June, 1886, she was in St. Thomas's, under the care of Sir W. Mac Cormac, with an extensive recurrent growth, which proved to be a very vascular sarcoma. In October, 1886, she came under Mr. Jessett's care. The whole of the hard palate and most of the soft palate were implicated. Respiration could not take place through the nose. On Nov. 9th the operation was performed. Two incisions were made extending from either angle of the mouth upwards and outwards towards the outer angle of the orbits. The whole flap, which included the nose, was reflected upwards over the forehead, and the whole of the tumour was thus freely exposed to view. With a fine narrow saw both superior maxillary bones were divided about half an inch above and parallel to the alveolar process. With a raspatory used as a lever this portion of the bones was separated from the upper and remaining parts. The separated bone was then seized with a lion forceps and the whole growth was gradually removed, with the exception of that portion which had grown into the left antrum. This was afterwards easily removed by the use of a Volkmann's spoon. There was scarcely any hæmorrhage. The skin flaps were brought together with hare-lip pins and the wound dressed with iodoform. She was fed with nutrient

Digitized by Google

enemata for the first twenty-four hours. The patient, who was shown, made an excellent recovery, and was still quite well three months after the operation. The growth was a mixed-celled sarcoma.

Mr. BRUDENELL CARTER spoke of the value of the revolving circular saw in the division of bone.

Dr. ANGEL MONEY said the tumour was a mixed-celled sarcoma, having a plexiform or columnar arrangement, and with some distinct myeloid cells.

Mr. MARMADUKE SHEILD said the tumour had an alveolar structure, and was composed of mixed cells, some of which had something of the appearance of myeloid cells, though they did not appear to have many nuclei.

Mr. J. H. MORGAN spoke of the historical value of Dr. Servais' paper, and congratulated him on the success of his courageous surgery.

Mr. H. ALLINGHAM referred to a case of removal of a tumour from the superior maxilla by Mr. Pick.

OBSTETRICAL SOCIETY OF LONDON.

THE annual meeting was held on Feb. 2nd, J. B. Potter, M.D., F.R.C.P., President, in the chair.

The following specimens were shown:—Dr. Amand Routh's specimen, which was exhibited at the last meeting of the Society, was reported by Mr. Alban Doran and Dr. W. S. A. Griffith to be a fibroid growing from the undeveloped horn of a uterus unicornis. Mr. F. A. T. O'Meara showed a Fœtus with the bladder so dilated and thickened that it nearly filled the abdominal cavity; the urethra was impermeable. Dr. John Phillips showed a dissection of a Fœtal Heart with two auricles and one ventricle, taken from a dicephalous monster. Dr. Horrocks exhibited an infant a week old suffering from Spina Bifida; the cyst had contained 50 oz. of fluid. Dr. M. H. Jones read remarks on the case.

Unilateral Galactorrhœa.—Dr. GIBBONS described this case. A lady, aged twenty-three, who had ceased nursing for six weeks, complained of constant running of milk from the left breast. After her first confinement she had nursed for five months with both breasts, when she had to give up on account of weakness, and an abscess formed in each breast and discharged for eleven months. After this, her second confinement, she at first nursed with both breasts, but the milk disappeared from the right one, and she continued with the left breast only for four months, and then discontinued, as it was thought that her milk disagreed with the child. Menstruation had not reappeared. There was no reason to suspect pregnancy, and there was no uterine disease. Although she was anæmic, the milk was of good character, and the amount that flowed was twenty ounces in twenty-four hours. Dr. Gibbons then enumerated the various remedies which he had used to arrest the secretion of milk, without result. These included arsenic, iron, strychnine, iodide of potassium, belladonna, bromide of potassium, quinine in large doses, compression of the nipple, opium, galvanism, faradism, rest and a dry diet. Menstruation appeared eleven months after the birth of the child, being preceded by a gradual diminution of the flow of milk, which continued over the second period and then ceased altogether, and the patient's condition became one of natural health. The author drew attention to the following facts:—(1) That the galactorrhœa was unilateral; (2) that the milk was of normal quality and quantity; (3) that there was no stimulus of nursing or of the genital organs; (4) while resisting all this treatment, it ceased spontaneously on the occurrence of menstruation. Authors were quoted as to the value of certain drugs in galactorrhœa, and cases were given illustrative of treatment by galvanism and faradism. Reference was made to the experiments of Roehrig to determine whether the nervous or vascular element has the greater influence over the secretion of milk, and resulting in favour of blood-pressure as the chief factor. Sinéty was also quoted, and, in conclusion, the speaker remarked that he had failed to find any case similar to the one brought forward. It was proposed and seconded that the discussion of this paper should be postponed till the next meeting of the Society.

The treasurer's report was adopted on the motion of Mr. Doran, seconded by Dr. Clapham, as were also the report of the hon. librarian, on the motion of Dr. Herman, seconded by Dr. Keele, and that of the Midwifery Board, on the motion of Dr. Playfair, seconded by Dr. Malins.

It was proposed by Dr. J. Williams, seconded by Dr. W. Black, and carried, that an alteration in the law regarding the meetings of the Society in January and October be made so that these meetings shall be held on the first Wednesday in each month, unless for some reason the Council should alter it—e.g., on account of the first day of the new year falling on a Wednesday.

The scrutineers (Drs. M. H. Jones and E. S. Tait) declared that the list of officers and Council as proposed had been adopted.

The President then delivered the annual address, which will be published in a future number.

A vote of thanks to the President for his address, and to the retiring officers and members of the Council, concluded the proceedings.

ACADEMY OF MEDICINE IN IRELAND.

Conservative Surgery in Diseases of Foot and Ankle.

AT a meeting of the Surgical Section held on Dec. 10th, 1886, Mr. WHEELER read a paper on Conservative Surgery in Disease of the Foot and Ankle-joint, in which he recorded several successful operations, including excision of the os calcis, of the astragalus, scaphoid, cuboid, middle, cuneiform, and metatarsal bones; also resection of the first phalango-metatarsal articulation. He described in detail the diseases requiring excision of the os calcis, the form of incision, and after-treatment. He condemned the subperiosteal operation in such cases. All his excisions of the os calcis were successful, and the locomotion of the patients was but little impaired. One of the cases he operated on died seven years after the operation from phthisis. The case of excision of the astragalus had been seen within a very recent period. The lady had a movable joint between the os calcis and malleoli, and possessed nearly equal powers in the foot operated on and in that unoperated on. In the case in which he removed the astragalus, os calcis, and the malleoli, with articular surface of the tibia, for disease of the bones, the patient had left for India last October, at which time he was able to wear a well-adapted boot and walk with the aid of a stick. Mr. Wheeler emphasised the necessity for carefulness in diagnosing the seat and cause of disease in the foot, likewise the stage the disease was in before undertaking partial operations.—The PRESIDENT had not found cases in which the disease was sufficiently limited to ensure satisfactory and permanent results by partial excision, and the want of such limitation was the chief reason why Pirogoff's operation was abandoned. Indeed, he was himself one of the first, if not the first, in this country to perform excision of the ankle-joint for caries, and he obtained what seemed to be a successful result—the wound healed and the patient had the use of his foot for two years; but at the end of that period the disease manifested itself again, and contemporaneously with it there was also evidence of tubercular disease of the lungs, which prevented further operative measures. Mr. Wheeler seemed inclined to disparage the subperiosteal method, without giving definite reasons. While the advantage of some excisions by that method were exaggerated, as in excisions of the elbow-joint, yet in others there was no doubt that it was useful, especially in the shoulder-joint, and the excision of shafts of bone, as the fibula, radius, and ulna; for in the young the preservation of the periosteum was of great importance. In excision of the elbow he did not think that better results were obtained by this than the older method.—Mr. CROLY had performed a great number of operations for disease of the ankle-joint, and he did not like the operation for excision of the os calcis. He had not had success in saving the foot where the disease seemed to be confined to the os calcis. He removed the os calcis by a horse-shoe incision where the rest of the bones seemed sound, but it turned out that they were infiltrated. He had had, however, a most successful case in private practice of excision of the os calcis for gunshot injury where the bone was shattered and shot had lodged in it, and the gentleman now had a useful foot. He had met with another case of great interest. A man fell off a horse injuring his ankle-joint, which exhibited all the evidence of compound fracture. Amputation was proposed, but the man refused to allow it. Months afterwards, when under his care, he cut down under the ankle-joint and found the astragalus was detached, and that the tibia had come down and accommodated itself on the os calcis. The man was now engaged as a coachman and

Digitized by Google

groom with a useful foot. The advantage of saving the periosteum of the os calcis bore no comparison to that of saving the periosteum of the shaft of the bones.—Mr. BARTON distinguished between caries from disease of the bone and that from accident, which was approached by the surgeon on different lines. The experience of the practical surgeon was unfavourable to gouging or partial operations where there was extensive caries or the disease was diffused. Hutton, who had operated as Mr. Wheeler did, discountenanced the then new procedure as leading to an unsatisfactory result, and yet Mr. Wheeler, by removing a similar amount of bone without following the same line of incision, had obtained success. He himself had attempted to save a foot of which the disease was only partial, and his experience was that while he had been successful in some cases, yet in a great many he had been unsuccessful, and it would have been better for the patients had he performed Syme's operation at first.—Mr. FRANKS said the unsatisfactory results of partial excision were due in the first instance to foci of disease being left untouched, and, secondly, to operating on patients who had sunk so low in health that they had no recuperative power in them. At the same time, the condition of the patient was often made too much of in these days of antiseptic surgery, and therefore conservative surgery might be adopted with more hope than before. In tubercular disease, however, health was a great factor: everything depended on the constitution of the patient, and caries sometimes got well without operation at all. The tendency of surgery was to the partial excisions, especially in view of the success achieved by Ollier of Lyons, who was a great advocate for subperiosteal operations. It was obviously better to leave a periosteum that could develop bone rather than excise it with the bone, and hope for a pad of cicatricial tissue to walk upon.—Mr. HENRY FITZGIBBON remarked that, in considering the question of excision, the main point was what was the primary cause of disease in the bones. The great distinction was between disease of bones resulting from accident and disease arising from constitutional cachexia.—Mr. WHEELER replied.

Addison's Disease.—Select Clinical Reports.

At the meeting of the Medical Section held on Dec. 17th, 1886, Dr. DOYLE read a paper on a supposed case of Addison's Disease occurring in a dark-complexioned female somewhere between twenty-two and twenty-five years of age, having brownish and bronze-looking pigmentation of the temples, cheeks, backs of hands, and front of legs. Constitutional symptoms preceded the pigmentation by nearly three months. Ill-health first commenced with an unhealthy ulcerated condition of one of her fingers. This patient was said by her friends to have recovered, but that slight discolouration remained along attachment of the hair to the temples. The chief interest connected with the case was to discover the primary disease that gave rise to weakness, lassitude, vomiting, cough, fever, and discolouration.

Dr. A. W. FOOT read a communication styled "Notes of some Unusual Cases observed in Hospital Practice." One was a case of obstinate vomiting from "land-sickness," which continued for nine days after the man had come ashore. Another was a case of mistaken identity on the part of four persons. The man was living, but comatose from alcohol. A husband, wife, and two of their daughters claimed him as their son and brother—wrongfully as it turned out. There was a case of well-marked articular gout in a hospital patient, very corpulent, and long addicted to porter-drinking. The series concluded with an account of a man who was firmly convinced that he was the source of an offensive effluvium which made his presence unbearable and even injurious to others—animals as well as men. Dr. Foot called this, and some similar cases which he alluded to, by the provisional name of "subjective osmidrosis." The question was discussed of an hallucination of smell or organic irritation of the sensory centre.—Dr. COX said he had himself a tendency to sea-sickness which lasted for some hours after he came on shore. He had had two cases of acute articular gout. One was that of a butler, who was considerably improved under a treatment of colchicum and lithia, and subsequently iodide of potassium. The other was that of a policeman; bromide of lithia gave him considerable relief, and the administration of salicylic acid seemed decidedly beneficial. Other patients he had seen relieved by ointment of belladonna and iodine, with powder of opium or the extract of opium. With reference to the curious case of delusion, he might state that at present he had under treatment a man who was sensitive of emitting a disagreeable smell, which might be the result of disease of the bones of the nose or of mischief at the back of the pharynx.—The PRESIDENT had himself been consulted three years ago by a gentleman on account of a bad smell which, he said, emanated from his body and made him offensive to everyone around him. He saw that the gentleman was under a delusion, and endeavoured to convince him of the fact. Once afterwards he again saw this gentleman, who had, he believed, given up the idea. As to remedies against hallucination, even specialists seemed to have forgotten the great results published many years ago by Seymour of London as to the value of opium in cases of hallucination and melancholia.—Dr. FOOT replied.

MIDLAND MEDICAL SOCIETY.

A MEETING of this Society was held on February 2nd, Mr. Lloyd Owen, F.R.C.S.I., President, in the chair.

Gunshot Wound of Vertebra.—Mr. J. T. J. MORRISON showed a man aged twenty-five who nine weeks ago, in a fit of depression, shot himself in the mouth, discharging a No. 7 conical Eley bullet from an ordinary revolver. On admission there was some shock, but no loss of consciousness. The tongue and palate were blackened with powder; the soft palate presented a round perforation, through which the tip of a finger could feel an opening in the bony wall of the pharynx; a probe passed through this aperture, traversed a canal about an inch in length in the bone, and impinged on a hard substance at the bottom. There were no signs of spinal concussion or hæmorrhage. No operative treatment was adopted for the extraction of the bullet. The patient is now in excellent health, the hole in the vertebral column being filled up and its place indicated by a slight elevation.

Fractured First Rib.—Mr. A. F. MESSITER exhibited a specimen of fracture of the first rib from a man aged seventy, who had been run over by a cart, and died shortly after admission from collapse. At the post-mortem examination the sternal end of the right clavicle was found to be dislocated forwards; the first rib was broken at the spot where the subclavian artery passed over it; the second was fractured at its middle, and the third and fourth behind their angles, the latter wounding the lung; there was no other injury. Mr. Messiter considered that the clavicle after dislocation was pressed down on the first rib, thus fracturing it by direct violence. The periosteum was torn on the under surface of the bone, but was intact on its upper surface.

Mr. J. W. TAYLOR showed some Female Catheters made of Glass. He uses them for operation cases whenever a catheter is required, and finds them very clean and inexpensive. He also exhibited his "Artificial Amnion," a simple form of uterine dilator and tampon. Both instruments may be obtained from Messrs. Mappin of Birmingham.

Rupture of Abdominal Aorta.—Mr. L. TAYLOR showed for Dr. Oliver Field a specimen of Rupture of the Abdominal Aorta, taken from a boy aged eight. Half an hour before his admission to the hospital he was run over by a brewer's cart. On admission he was suffering from great shock and was much blanched, the abdomen being moderately distended; he died in an hour. On post-mortem examination a considerable quantity of blood was found extravasated behind the peritoneum, and there was a large rent in the abdominal aorta, where it divided into the two common iliacs, the abdominal viscera being uninjured.

Mr. DONOVAN read a paper on "Some points in Therapeutics."

WOLVERHAMPTON AND DISTRICT MEDICAL SOCIETY.

A MEETING of this Society was held on Jan. 4th, Dr. S. A. Smith, President, in the chair, when the following specimens were exhibited:—

Mr. VINCENT JACKSON showed a girl aged fourteen, sent to him on account of alarming symptoms occasioned by the presence of a large adenoid bronchocele. To relieve her symptoms of asphyxia Mr. Jackson completely divided the very broad isthmus, and removed a small portion. The operation was followed by complete departure of the distressing symptoms, and by a visible diminution of the size

Digitized by Google

of the tumour, amounting, as ascertained on measuring the circumference of the neck, to one inch. The wound healed quickly.

Dr. EVANS showed a case of Splenic Leucocythæmia in a child aged twelve. The spleen extended down to the pubes, and occupied the greater part of the left side of the abdomen; it had grown rapidly during the last two months whilst under observation.

Mr. VINCENT JACKSON exhibited (1) a large loose cartilage removed from the right knee of a gentleman aged thirty-two. Its removal was accompanied by a free incision of the skin and capsule of the joint. A rapid recovery followed in fourteen days. The operation was done with antiseptic precautions. A drainage-tube was kept in the joint for two days. Also (2) a large multilocular ovarian tumour of almost solid character successfully removed from a woman of fifty-two years of age. It was connected by tough adhesions to the walls and contents of the abdomen, and an innumerable quantity of bleeding points required deligation, including some on the intestinal walls. Rapid recovery followed the operation. A glass drainage-tube, withdrawn at the fourth day, was used.

Intestinal Obstruction and the Difficulties in the Way of Diagnosis.—Dr. TOTHERICK read a paper on this subject, and remarked that in this respect age had an important bearing, for in children the cause was generally either intussusception or peritonitis, and in aged persons either impaction of fæces or malignant diseases. He advocated the use of repeated enemata of water or oil in those cases due to impaction of fæces. In acute cases, where the diagnosis is uncertain but the fatal termination sure, exploration by abdominal section was advised. Of all drugs opium was most generally useful, and in cases of impaction saline aperients might do good. In simple inertia of the bowels due to repeated constipation and over-distension he had found faradaism very useful.

PLYMOUTH AND DEVONPORT MEDICAL SOCIETY.

THE monthly meeting of this Society was held at Plymouth on Wednesday, Feb. 2nd, Dr. C. Aldridge presiding.

Mr. W. J. SQUARE read an interesting paper on Cystic Tumours of the Breast, and related a recent case of Lymphatic Cyst treated by Evacuation, followed by the continued application of a liniment after Sir B. Brodie's formula, with excellent result.

Dr. BAMPTON opened a discussion on the Treatment of Typhoid Fever, advocating the use of quinine in large doses and cold applications to combat hyperpyrexia, where the cold bath treatment was not practicable, or where tepid sponging was insufficient. The administration of antipyrin had in his hands been followed by marked lowering of temperature, accompanied by profuse sweating, and succeeded by refreshing sleep. No untoward symptoms were manifest. Maltine was suggested as a valuable dietetic adjuvant. Stress was laid upon the cautious return to farinaceous food or fish at a considerable interval after the normal temperature had been reached. The routine treatment of cardiac exhaustion in the later stages of the fever with brandy was pointed out to be a mistake, and a more scientific and rational discrimination, based upon a knowledge of the different qualities and properties of the various alcoholic liquors, in the selection of so potent a remedy, was pleaded for. The more highly etherised wine, as old sherry, was indicated in cases of cerebral or cardiac exhaustion. Surgeon Russell, A.M.D., bore testimony to the efficacy of the cold bath treatment, not only in controlling and lowering hyperpyrexia, but also its ability to prevent its access. An interesting discussion followed, to which a large number of members and visitors contributed.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The annual festival in aid of the funds of this institution was held on the 9th inst., the Right Hon. the Lord Chancellor (Lord Halsbury) occupying the chair. During the evening, the secretary, Mr. Burford Rawlings, announced that the subscriptions received towards the Jubilee Fund amounted to £1183. The object of this fund is to enable the whole of the hospital accommodation to be taken into use, wards containing fifty-five beds out of a total of 180 not having been as yet in occupation.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

TUESDAY, FEBRUARY 15TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

As soon as the Council was formed,

Dr. MCVAIL, on a point of order, said he desired to raise a question with reference to the appointments of several of the members, which he said had been made by the Senatus Academicus of the Scotch Universities.

The PRESIDENT interposed, and stated that the question about to be raised by Dr. McVail could not be brought forward without notice of motion.

Dr. MCVAIL said he would give the requisite notice.

The PRESIDENT then delivered his address to the Council. He said:—"The difficulty of condensing within reasonable space the topics which demand the attention of the Council has never been as great as on this occasion. The Council now meets, for the forty-first time, enlarged, under the Medical Act of 1886, by seven members, with the addition, since the Act passed, of a representative from the Victoria University. These eight members, with a newly-appointed Crown Nominee for Ireland, and a new member for the Apothecaries' Society of England, form almost a third of the entire Council. It would seem, therefore, culpable not to endeavour to place before you a short statement of the work that lies before us. This is the less easy, because, although every member of the Council is acquainted with our duties, yet most would admit that we do not all look at them from the same point of view. Of this, however, I am sure, that you will believe in my earnest desire to place before you, as briefly as possible, such facts only as have a practical bearing on the important work that brings us together to-day. We meet in the present year under conditions which have no precedent, and which can never recur. The year of the Queen's Jubilee, with all that this implies, suggests to every body of Englishmen who have been charged with national duties thoughts of change from the known to the unknown, even though they are, in the main, thoughts of thankfulness and hope, of progress and peace. In no public body can these thoughts, and the questions which attach to them, be more important and more deep than in one which fixes its attention on the changes which medicine has undergone in the last fifty years." The President then touched upon what he termed the progress of health notions during the Queen's reign, in regard both to curative and preventive medicine, and passed on to consider the progress of legislation in respect of medical education during the same period. "As regards the history of the duties assigned to the Medical Council," he said, "there is little need to concern ourselves. We have the power and duty to see (1) that no one legally enters the medical profession who is not fit for it; (2) that no one remains in the profession whose conduct has been professionally infamous; (3) that all necessary medicines may be officially sanctioned and scientifically prepared; (4) that due rights and privileges are accorded to all properly educated Colonial and foreign practitioners who are legally qualified in their own countries. It has taken seventy years of discussion to come thus far. An opportunity was lost in 1815. The agitation for comprehensive medical legislation began in earnest after 1830. A Bill was laid before Parliament in 1840. Principles of union were agreed upon by the great London authorities in 1848. In this same year a Bill was brought forward in vain by a powerful Minister, Sir James Graham, in concert with Sir Benjamin Brodie. Sir Benjamin's correspondence, consisting of hundreds of letters, about that date, is still in existence. All these and many other movements resulted, in 1858, in the Act which, constructed on broad principles, empowered, and therefore required, all the bodies connected with the legal authorisation of practitioners in medicine throughout Great Britain to place their education on adequate and uniform grounds. Twenty-nine years have passed, and now only last year has this been effected. Over the melancholy history of this delay a veil had best be drawn. Of the Act of 1858 we cannot, on the whole, speak too highly. Where it failed, it has failed through and by

Digitized by Google

reason of one canker of our nation—*amor sui, non patriæ*. Two expressions have been rife in this regard—and they have given rise to comment, and have caused offence on opposite grounds—the one, 'moral suasion'; the other, 'the battle of the shops.' These terms represent great forces in nowise peculiar to medicine. The former appeals to individual and to corporate conscience. The latter asserts the claim of supposed corporate interests. Seeing that neither of these forces rectified acknowledged evils, in 1870 the Government made an attempt to institute national licensing boards. The principles of the Government proposals were accepted by the Medical Council. These were to enforce uniform and adequate examination for entrance into the medical profession. Much fruitless labour has been expended in the sixteen years that followed, involving loss of time to the Council and to Parliament, and some loss of character to our profession. It is a sad chapter in the history of Parliamentary government and of free institutions. But this chapter is now closed, and closed in a remarkable way. There were two principles on which most persons with knowledge and of calm judgment seemed in 1870 to be thoroughly agreed—viz., (1) that the present Council was too numerous for the best form of executive, though perhaps this was an unavoidable evil in our day, pre-eminently a time of 'representation'; and (2) that the examining and licensing institutions were too numerous for uniformity of action. The Act of 1886, to which all who did not oppose it are practically parties, increased by a full fourth the number of this Council; and the institutions, with power to license separately, are more numerous by one than they were before. This is surely a strange result. It teaches a profound lesson for the future of medicine and of science. It is the lesson that it is an evil thing for a free country when its people and its institutions depend on Parliaments, and not on themselves, for matters which they themselves can, without compulsion, adjust and rectify. There are now, therefore, *twenty* independent bodies with power and duty to certify the fitness of the medical practitioners of Great Britain to practise every part of their profession; to grant higher titles to those who possess knowledge, general or scientific, or practical, higher than is essential for the generality; and to combine together for this national end in whatsoever manner they may severally determine. Once again the institutions are free, and, being free, are once more on their trial. It is almost needless to state here that while eleven universities still remain separate, the licensing corporations have combined, or are combining, into one in Scotland; they aim at becoming either two or one in Ireland; and they are two in England. When this is done there will be in all sixteen separate examining boards. A movement is in action in England to make a sixth degree-giving body, to be designated a university. Should this be accomplished, there will then be in England only one medical corporation. Whether these arrangements will hold, whether they are the best, whether some Government will arise to constitute three divisional licensing boards, as recommended by the Royal Commission on the Medical Acts, are matters on which it were idle now to speculate, and which do not concern this Council as a State-appointed Council of Education. We here lament the time that has been occupied, though necessarily occupied, in doubtful questions, administrative and political. These belong to another arena, and to voluntary associations. The work of regulating education by calm consultation of representative teachers from every part of the country has become great enough when we consider the vastly increased mass alike of medical knowledge and of opportunity. But it cannot be said that the principles of medical education are altered. That education must always be, as it always has been, though in varying proportions and of various quality, threefold—general, scientific, and practical. As regards the course of discussion and action which led up to the Act of 1886, it would improperly waste the time of the Council to say much. Not that the Governments of this period are justly to be blamed. The two great political parties have faithfully striven to do their best for us. Four Government Bills have passed the House of Lords, each of a more or less complete character. Discussions within the profession have practically checked the full proportion which these Bills proposed to give to a national system of medical education and examination. Voluntary boards, more or less complete, in England, in Scotland, and in Ireland, have been formed, dissolved, and in other guise formed again. And at length the Act which brings us together with our present numbers is law. As I have already said, eleven universities and nine licensing corporations are free to act as they will, within certain conditions. These conditions are practically defined by this Council, or by the Privy Council, or by both. They are chiefly to enable and require every body to examine and to license in every department of medicine: Universities in all subjects; Surgeons in medicine and midwifery, as well as surgery; Physicians in surgery and midwifery, as well as medicine; Apothecaries in all. As heretofore, any combinations may be made among the bodies with the view of combining and nationalising institutions still separate and numerous. And so ends the system of double and treble qualification, which has been the result of accident and the imperfect knowledge of former days, and the source of heartburning and confusion in our own. It remains now for this enlarged Council to bring clear and harmonious effort to a national task of interest and importance, interest and importance which are ever growing as biological science extends, as conceptions of national life and national conscience rise, and as the relations of the human family throughout the globe, and especially of the English-speaking race, are drawn more close, and are better understood."

The President then referred to the educational inquiries of the Council from its commencement, and to the business to come before the present Council, pointing out that the Council could delegate whatever it pleased of its multifarious business, except its judicial functions and condemnatory representations to the Privy Council, to the branch councils or special committees. He concluded thus: "I am painfully aware of the hopeless task which I undertook in making the abstract of medical progress in England which I have presented to you to-day. Of foreign countries I have not attempted to speak. Still, it seemed to be a clear duty, at this stage of the Council's history, to attempt a rough catalogue of the chief points which this Council has had before it during the last twenty-nine years, in its endeavour to establish the basis of a sound and uniform training for the medical student of the future. It has had much support from Government, and whatever aid can be derived from abundant criticism. This last would have had more real value had it fully appreciated the difficulties of a period of progress never equalled, and of changes in institutions naturally tenacious of their past. In dealing with the education of the medical student, we now are dealing with a subject which depends on some of the most difficult departments of science. For the science of medicine is in touch, on the one hand, with the science of many of the inorganic constituents of our earth, on whose nature there have of late been made fresh revelations from day to day; on the other, with the world of mind wherever manifested in living things. It is daily face to face with the tyranny of everlasting all-pervading Law, and yet is open to every ray of light by which from time to time is darkly shown the Cause of all. It cannot overlook the actions and reactions of matter and mind. It is entangled among the mysteries of Evolution and the effects of Heredity. It must note the decay as well as the growth of the individual and of the races of men. It revises with unsparing hand the data on which have rested the *juvantia et lædentia* of life which had the blind faith of our fathers before experiment altered some foundations of accepted clinical fact. It has to recognise as a stern reality that in some manner the laws of all other living things are the laws by which, free-will notwithstanding, we also have our being. It explores what connexion may be found in the origin and development of all living things. It has to struggle for the alleviation, though it does not trouble itself to solve the mystery, of pain. It seeks to appreciate what are the principles of the universal pathology which underlie the life history of the vegetable world, and the bodily sufferings and the mental agonies of man and brute alike. It is the function of this Council to represent interests intimately connected with all these topics through the seats of universal research and universal learning. It considers the long experience of the institutions which watch over the practical and beneficent exercise of the healing art, and which are in sympathy with the whole body of faithful workers among practitioners. The Council has to contract the impossible and unnecessary in education into that which is possible and necessary; it must so limit purely scientific studies that they may be directly subservient to the health and the wants of the public as distinguished from the profession of medicine—

Digitized by Google

that public whose welfare is here expressly represented by the Crown. We live, in short, in a constant endeavour to advance the study of an art which ultimately will rest on science, and to ensure such progress and knowledge as will give us scientific practice not divorced from rational empiricism. It is no slight happiness to those who have long watched the changes of our time to know that there are now in our medical schools many who, judged by the tests of love for truth, desire for knowledge, and benevolence of purpose and personal character, may stand comparison with any youths of any place or any profession. To them belongs the task of reaping the harvest of knowledge which this age has sown, and which cannot yet be fully gathered in. Many have the temper of reverent and earnest inquirers into the order of things under which, for a little span, we have all been placed, and in which they, being in constant contact with the sufferings of other men, have deep concern. In their progress and in their lives will be the great reward of the Court of Education."

It was moved by Mr. MARSHALL, seconded by Dr. HUMPHRY, and agreed to—"That the President's address be entered in the Minutes, and that the thanks of the Council be accorded to the President for this address."

The Finance Committee having been appointed, a table showing results of professional examinations held in 1886 for qualifications granted under the Medical Act by the bodies named in Schedule A of the Act, also a table showing results of preliminary examination in 1886, compiled by the registrar from such returns as have been supplied by the examining bodies, pursuant to the Council's request, were presented.

With reference to the latter table,

Dr. A. SMITH called attention to the fact that the Apothecaries' Society of London had passed 214 candidates and rejected 447, and that the Faculty of Physicians and Surgeons of Glasgow had passed 65 and rejected 159. These results, he said, showed either that the examinations of the bodies in question had become much more stringent, or that the education of the candidates was very defective.

Mr. MACNAMARA called attention to the circumstance that in regard to the highest percentage of marks obtained by the candidates, several of the universities had stated that information could not be supplied, and he urged the desirability of returns being made as to the lowest amount of information considered satisfactory by the examining bodies in preliminary education.

A table was then received showing the number of exceptional cases that occurred during the year 1886 in regard to the length of the course of professional study, together with a statement of the action taken thereon by the several licensing bodies; and another table showing results of professional examinations held in 1886 for qualifications granted under the Dentists Act.

With regard to the former table,

Dr. STRUTHERS said it would be observed that the number of exceptional cases had greatly decreased since last year. The only bodies in which they had occurred were the Royal College of Physicians of London and the Royal College of Surgeons of England, in which the number of cases was 39 and 22 respectively. That number seemed to be large, and to require some explanation.

Sir DYCE DUCKWORTH said that the cases that had occurred in the College of Physicians related chiefly to Colonial graduates. Only three or four had come from foreign universities, and in those cases the diplomas had been closely scrutinised, not only to ascertain that they were themselves genuine, but that the education was satisfactory.

It was resolved that the registrar should be directed to inquire in future into the details of such exceptional cases.

The usual communications were received from the Army and Navy Medical Departments, in answer to the applications of the Council.

A preliminary report by a subcommittee of the Executive Committee on the Visitation and Inspection of Examinations was presented, together with certain suggestions by Mr. Simon on the subject, and recommendations by the Executive Committee.

Mr. MARSHALL, in bringing up the report, suggested that the subject was so urgent and important that it ought to be dealt with by a larger body than the Executive Committee; and he proposed that the subject should be referred to a committee of the Council for consideration and report during the present session.

Dr. [illegible] WATSON seconded the proposal.

Dr. STRUTHERS said that the report proceeded on the assumption that the inspectors should be appointed only with reference to medicine, surgery, and midwifery in their limited sense at the final examination. He thought that the words of the Act had a more extended sense, and should be regarded as referring to all that led up to those subjects. It was as important to inquire into the earlier examinations as it was into the final. They were in reality the foundations on which the later subjects were built. He quite agreed with the suggestion of the committee that there should be inspectors for the three divisions of the kingdom, and that they should not be limited to one division. An international arrangement would certainly be the most satisfactory. As to the nature of the inspection, it should not be of so detailed a character as some former inspections.

Dr. HAUGHTON thought that the inspections should be confined to the final examinations. In the case of the universities, at any rate, the preliminary examinations might be left to take care of themselves.

Dr. QUAIN, in supporting the motion, said that the inspectors were not to be mere visitors, but were required to examine into the question whether the standard of proficiency was such as "sufficiently to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery."

Sir WILLIAM GULL moved as an amendment that the Council should on the following day take into consideration Section 2, Subsection 3, of the new Act with reference to inspection. If that course were adopted, the report of the committee could of course be considered.

Dr. MATTHEWS DUNCAN said that the old visitations might still continue with regard to preliminary subjects, and that the inspection required under the new Acts should have reference to medicine, surgery, and midwifery.

Sir WILLIAM TURNER said he concurred in the suggestion of Sir William Gull that the Council should take the special clause of the Act into consideration. If Mr. Marshall would embody in his resolution a reference of that clause to the proposed committee, it would be more satisfactory.

Mr. TEALE supported the same view.

Mr. SIMON thought that the Council ought at an early period to decide the question of the narrow or the enlarged meaning of the words "medicine, surgery, and midwifery," and not refer it to a committee for solution. That, he thought, would save time, and facilitate the labours of the committee. He should like at the proper time to move as a rider to Mr. Marshall's resolution, "That it be an instruction to the committee that the Council desires its inspection of examinations to cover the entire range of those branches of knowledge which it has declared in its Recommendations to be essential constituents of the qualification of a candidate for licence."

Dr. HUMPHRY said he would propose as a substitute for Mr. Simon's proposed rider the first recommendation of the Executive Committee—namely, "That, reserving for future action the visitation and inspection of the examinations in the earlier subjects of professional education, the Executive Committee recommends to the Council that the first year's appointment of inspectors provide for the inspection of examinations in medicine, surgery, and midwifery."

Sir WILLIAM GULL said he was willing to withdraw his amendment if it were understood that under Mr. Marshall's motion the whole bearing of the subsection of the Act would come before the Council.

Mr. MARSHALL said he was willing to include the consideration of Sections 2 and 3 in his resolution.

The motion was then put and agreed to in the following form:—"That Sections 2 and 3 of the Medical Act of 1886, together with the foregoing preliminary report by Dr. Humphry and Dr. Quain, on the Visitation and Inspection of Examinations under the Medical Acts of 1858 and 1886, with certain suggestions by Mr. Simon for the Council's future Inspection of Examinations, and the recommendations by the Executive Committee, be referred by the Council to a committee, to report on the subject to the Council at its present session."

The committee was then appointed, and Mr. Marshall was requested to act as chairman.

Mr. MARSHALL brought up various communications on the subject of diplomas in Sanitary Science for entry on the Minutes. He stated that the schemes and curricula all coincided in requiring that the candidates presenting themselves should be registered practitioners, and in some instances the candidates were required to be graduates in

Digitized by Google

medicine of the university giving the diploma, or of some other body.

A communication was received from the University of New Zealand, applying for the recognition of its diplomas. It was ordered to be entered on the Minutes.

Communications were also received from the Apothecaries' Hall of Ireland, and the King and Queen's College of Physicians in Ireland, with reference to a conjoint scheme of education and examination, and ordered to be entered on the Minutes.

The remainder of the sitting was held in the absence of strangers.

WEDNESDAY, FEB. 16TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The Apothecaries' Hall of Ireland and the Conjoint Scheme.

Dr. STRUTHERS brought forward the following motion:—"With reference to the 'scheme for constituting an Examining Board in Ireland by the King and Queen's College of Physicians and the Royal College of Surgeons in Ireland,' received and entered in the Minutes of Nov. 20th, 1886, page 154; and to the communications to the Council from the King and Queen's College of Physicians in Ireland of Nov. 10th, 1886, and the Apothecaries' Hall of Ireland of Nov. 9th, 1886, received and entered in the Minutes of Nov. 19th, 1886, page 145; and to the 'Remarks,' with Appendix, by the King and Queen's College of Physicians, of date Dec. 31st, 1886, transmitted to the President by the College on Jan. 5th, 1887, and the 'Comments' thereon by the Governors and Court of the Apothecaries' Hall of Ireland, transmitted to the Registrar of the Council on Feb. 3rd, 1887, and received and entered in the Minutes of Feb. 15th, 1887: that the Council request the King and Queen's College of Physicians and the Royal College of Surgeons in Ireland to reconsider the scheme, in the strong hope that they may be able to arrange with the Apothecaries' Hall of Ireland a scheme which shall include the Apothecaries' Hall with the two Colleges." He said he did not appear in any way as a special pleader for the Apothecaries' Society, but as performing what he considered a public duty. It was somewhat difficult to frame the motion because there was not now before the Council any motion for the approval of the scheme; but they had the scheme on their Minutes, and therefore could deal with it. The motion was simply that the Council should advise the two Dublin Colleges to reconsider the scheme with a view of admitting the Apothecaries' Hall into a triple scheme. If the apothecaries were left out of the scheme what was to happen? By the Act of 1886 it was provided that a medical corporation might apply to the Council to have examiners appointed, and if the Council declined to do so the body might go to the Privy Council, and if it appeared to the Privy Council that the General Council had failed to secure the maintenance of sufficient examinations, or that occasion had arisen for the General Council to appoint assistant examiners, then the Privy Council might notify their opinion to the General Council, and if the General Council failed to comply with such directions of the Privy Council, the Privy Council might themselves appoint assistant examiners, and the Apothecaries' Hall of Dublin might be started as a new and independent licensing body for medicine, surgery, and midwifery. That was the prospect before them, and if that were the case they might have the profession in Ireland and England flooded with practitioners, whatever their professional knowledge might be, under the name of "apothecaries." This question had been discussed very elaborately on former occasions by the Council; and in 1863, in answer to an application from the War Office, the following resolution was agreed to: "That this Council is of opinion that the registered licentiates of the Apothecaries' Company of Dublin are as apothecaries entitled to practise medicine in Great Britain and Ireland." The result was that the army and other boards received the apothecaries' diploma on the same footing as any other medical licence. After tracing the history of the establishment of conjoint examinations, he said that the other Colleges of Physicians and Surgeons must make up their minds to part with a few of their privileges and fees, and that the examinations must be made, though upon "reaonable terms." He made the motion on three grounds: first as a measure of justice due to the apothecaries; secondly, as a matter of expediency to the other bodies; and thirdly, as a public duty. It was not for the interests of the public that these bodies should be tolerated as independent licensing bodies, flooding the country with practitioners with their name and qualification. He moved this as a measure of peace. If they had the three corporations united into a conjoint board, they would have an end to contention; if not, it would be every man for himself.

Dr. BRUCE seconded the resolution.

Mr. SIMON, in supporting the motion on the ground of the demands of public duty, said: Could any reasonable person say that it was for the public interest that a separate and competing examining board should be set up in Dublin? No one would contend that it was. In proportion as the College of Physicians felt itself stronger and higher than the Company of Apothecaries, it was bound to adopt the course which was urged upon it. *Noblesse oblige.* They ought not to allow any narrow personal feeling to stand between them and the completion of a scheme that would be for the general good of the country. It could never be for the public benefit that the two corporations should force the Company of Apothecaries into a position in which they would have to take refuge in the power of the Privy Council or the Medical Council to appoint assistant examiners. The Apothecaries' Company had been legally recognised, whether wisely or not, as a medical authority, and the question was whether they were prepared to assent to a course which would make that body a competing authority against the two Colleges in Dublin.

Mr. WHEELHOUSE maintained that the Company of Apothecaries in Ireland did not give a really full qualification. If, therefore, the Council advised the Colleges in any other sense than that of Dr. Struthers' resolution, it would be favouring the establishment of a new corporation very ill equipped for its purpose. He accordingly supported heartily the proposal of Dr. Struthers, believing that if the Apothecaries' Company were not admitted to the conjoint examination infinite harm and mischief would be done.

Mr. TEALE said he desired emphatically to endorse the motion, believing that its rejection would be a public calamity.

Dr. BANKS also supported the motion, and said that it would be discreditable to the Council if it favoured the creation of a new body in Ireland.

Sir WILLIAM GULL, in supporting the motion, said that the same principle would equally apply to this side of St. George's Channel. The Apothecaries' Company had a distinct function to perform, and on public grounds therefore it ought to be maintained. The Council, he thought, would stultify itself if it did not adopt the motion of Dr. Struthers.

Dr. GLOVER said that recent legislation did not contemplate the destruction of existing bodies, but rather their continuation. As therefore the number of bodies could not be diminished, the only hope they had was in their fusion. With that view, and believing that, after all, the pharmaceutical side of medicine was very important, perhaps more important than ever, he was quite prepared to give a hearty vote in favour of the motion of Dr. Struthers.

Dr. KIDD said that the feeling of the profession in Ireland was that the three bodies ought to be fused, and that it would be a very serious injury to the community if a body were established to compete with the two Colleges in their conjoint scheme. Such a rivalry would be a competition downwards, and not upwards. As to the legal position of the Apothecaries' Company, he would remind the Council that the College of Physicians accepted the first examination of that body as equivalent to their own first examination. He did not see how the dignity of the College of Physicians was affected. The intention of the Act of 1886 was to include the Apothecaries' Hall in any conjoint scheme, and it was the duty of the Council to encourage such inclusion.

Sir WM. TURNER said Dr. Struthers' statement was so convincing that he felt there was nothing left for him but to support the motion. There was one aspect of the case which was of very great importance—viz., what was in the mind of the legislature as regards this question when they framed the Act of 1886? They necessarily put into the front rank that which they considered to be the most important, and that was "combination." The mind of the Legislature was that combination should take place wherever it was possible, but that if through any difficulty combination did not take place, then that a body which could show that it was doing its duty efficiently should not be extinguished. What, therefore, they should urge upon the

Digitized by Google

bodies was that they should strive to carry out what he believed to be the prime meaning of the Act, and that the alternative proposition should not be required to come into operation if combination could be performed.

Mr. COLLINS hoped that the Council, if it passed this resolution, would also pass a resolution of which he had given notice—that they should nominate one examiner in surgery for the Apothecaries' Hall of Dublin, which he represented. If this was not done, and the recommendation of the Council was not adopted, the effect would be that that body would be disfranchised, at any rate till the next meeting of the Council in June. The Apothecaries' Hall were most anxious and willing to form a tripartite scheme, or if not a tripartite scheme a dual scheme, with the College of Surgeons.

Sir DYCE DUCKWORTH said he could not follow Sir William Gull in regarding this question as having brought before the consideration of the Council the other question which had to do with London. The question of the Apothecaries' Hall in Dublin, and its relation to the Royal College of Surgeons, was not at all on all fours with the question of the relations of the English bodies. The action taken by the London Colleges was perfectly well known. It had been taken after very full and careful deliberation. He entirely disagreed with the bugbear that had been held out as to the terrible consequences that they were to expect. They were told that a great injustice would be committed, that the country would be flooded with an inferior order of practitioners, and the public would suffer. He denied that the public would suffer from anything of the kind, because by the Act of Parliament it would be the duty of the Council to see that any other examination which might be adopted was one worthy the confidence of the public, and, therefore, if the Council did its duty the public would not suffer.

Mr. MACNAMARA said, as representative of the College of Surgeons in Ireland, it could not be expected that he should give a silent vote. The Council of the College of Surgeons had on several occasions gone to the College of Physicians to represent the justice of admitting the Apothecaries' Society into the conjoint scheme. He thought the resolution proposed by Professor Struthers, and for which he would vote most heartily, that the scheme should be sent back for the consideration of the College of Physicians, was a most desirable one, and it would be a sad thing if the College of Physicians would not listen to the voice of the Council on this point. A competing body would then be established in Ireland. He did not want to say that it would be an unworthy competing body, but it would become the duty of the Council to see that it was not so, and that would throw a great expense upon the Council.

The Council then rose for its customary ten minutes' adjournment, and on resuming held a private sitting, at which Mr. Muir Mackenzie attended for the purpose of giving legal advice. On the admission of "strangers,"

Dr. A. SMITH resumed the discussion on the motion of Dr. Struthers. After quoting from evidence given by Mr. Macnamara in 1874 to the effect that he considered that the present system of licensing in Ireland had been attended with a paralysing effect on the promotion of pharmacy, and that the Apothecaries' Company had abnegated their functions in becoming examiners in medicine, he proceeded to give an account of the proceedings taken by the two Colleges in reference to the application of the Apothecaries' Company to be admitted to the joint examination. When that application was received the Council of the College of Physicians held a special meeting, at which it was decided, *nem. con.*, that the Council of the College regretted its inability to accede to the proposal, because it believed that the intentions of the Medical Act were best carried out by the arrangement that had been made in accordance with that in force in England. In consequence, however, of a letter received from the College of Surgeons suggesting a modification of the scheme with a view of including the Apothecaries' Hall, another special meeting of the Council was held, and a resolution was carried by 17 to 4 declining to reopen the question of the constitution of the joint examining board. Under these circumstances he (Dr. A. Smith) thought it was hopeless to send the matter back to the College of Physicians for reconsideration.

Mr. BRUDENELL CARTER said he had for some time been familiar with the matter that had been brought before the Council by Mr. Muir Mackenzie, and he was quite prepared to hear that the Council could in no way control or influence the combinations of corporations. It would, he thought, be unworthy of the dignity of the Council to address a petition to the College of Physicians the prayer of which it had no power to enforce; he was therefore unable to vote for the motion of Dr. Struthers.

Dr. STRUTHERS briefly replied. He said that the opinion of Mr. Muir Mackenzie had nothing to do with the matter. The Council was only offering a piece of advice, and not seeking to exercise control.

The motion was then put and carried by 19 against 4, five members not voting.

The Council then adjourned.

THURSDAY, FEB. 17TH.

After a short sitting in private, Mr. Collins proposed a resolution for the appointment by the Medical Council of an examination in surgery for the Apothecaries' Hall in Ireland; but after discussion he ultimately assented to an amendment by Dr. Struthers deferring the consideration of the question until the result of the previous motion on the subject had been ascertained.

The Council then considered the subject of a memorial sent to the Privy Council, and thence transmitted to the Medical Council, complaining of the inefficiency of the clinical teaching of the Royal University of Ireland and of the inaction of the Medical Council. After some discussion the question was referred to a committee to report to the Council. On the motion of Dr. Heron Watson, a resolution was passed expressing the desirability of obtaining an opinion from the legal advisers of the Government in regard to the position of the Council in relation to medical authorities combining for examinations. Some discussion then took place in regard to the subject of dental finance, and the Council adjourned.

[A fuller report of this day's sitting will appear in our next issue.]

ON THE CAUSE OF MARKED HYPERTROPHY OF THE ANTERIOR WALL OF THE URINARY BLADDER.

To the Editors of THE LANCET.

SIRS,—On Jan. 18th I brought before the Pathological Society for criticism a novel and, I believe, an important fact which I had noticed whilst cutting frozen sections of pathological urinary bladders—namely, the increased muscularity of the anterior wall as compared with the posterior in certain cases of obstructive hypertrophy. In THE LANCET of the 12th inst. Dr. G. N. Pitt has given a very clear and certainly a very plausible explanation of that phenomenon. At the same time that I would acknowledge its partial value and partial truth, I would give my reason for having rejected the hydrostatic law that explanation is based upon, as being the sole cause for the production of the localised hypertrophy. Dr. Pitt says, "If membranes in the shape of spheres of varying sizes enclose fluid, so that the tension is uniformly distributed along each fibre, the thickness of the membrane must, by the principles of hydrostatics, be exactly proportional to the radius of the corresponding sphere"; and thus it is that the anterior wall, having a greater curvature than the posterior, must be thicker than the posterior in order that "the pressure of urine in the bladder may be balanced by the same tension of each muscular fibre." If, however, we carefully inspect the hypertrophied anterior wall more closely, we shall see that its composition does not conform with the law just enunciated. There are two main muscular strata—the circular and the longitudinal. Which has the greater curvature? The longitudinal. According to Dr. Pitt's explanation the longitudinal layer should be the thicker. But this is not so. If we examine any frozen section, we shall see that it is the *circular* stratum which has so greatly hypertrophied, and that it is often twice as thick as the longitudinal. I remain, Sirs, yours truly,

George-street, Hanover-square, Feb. 12th. E. HURRY FENWICK.

SIR HENRY THOMPSON has just been elected "un Membre Associé" of the Société de Chirurgie de Paris, having for some years been a corresponding member.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 19, 1887.

THE General Medical Council has again returned to its labours, and this time strengthened by those of its members who represent the great body of the profession throughout the three kingdoms. Its President (Sir HENRY ACLAND) inaugurated the session by the delivery of an address on the work of the Council, past and present. His discourse, not unnaturally, included a brief summary of the progress in medical and surgical knowledge since Queen VICTORIA came to the throne, and here he was able to show that a notable advance had been made. In his account of the progress of legislation in respect of medical education and examination, he had no alternative but to tell the story of numberless failures, of prolonged delays, and finally of but partial success. The blame cannot rest upon Parliament, for, as Sir HENRY ACLAND stated, the two great political parties have faithfully striven to do their best. The troubles have been created by the profession itself, or, rather, by those corporate bodies which have for years been held to represent its views. In the rivalry and the jealousy which they have shown towards each other is to be found the cause of the difficulties which have prevented medicine taking her proper place in this country.

We would gladly have seen Sir HENRY ACLAND lay greater stress on that great political change which enables the profession to be directly represented on the General Medical Council, and which recognises that there are rights and privileges to be guarded which are greater than those which have been held in view by the bodies whose representatives have heretofore determined all questions relating to the welfare of the profession and of the public. No doubt, as the President pointed out, the Council was already too large for the performance of effectual work; but so long as the system of representation is maintained this obstacle is insuperable. We believe, however, that the additions which have lately been made to its number will be found of value, if not in accelerating the work it has before it, at any rate in bringing it into more immediate relation with the majority of those who are actively engaged in curing disease.

The first important decision at which the Council has arrived will undoubtedly give almost universal satisfaction, and will raise the hope that the corporate bodies will not be deterred by a mistaken vanity from adopting a course which is urgently needed in the public interest. The decision was taken, upon a motion by Dr. STRUTHERS, that the Council should request the King and Queen's College of Physicians and the Royal College of Surgeons in Ireland to reconsider their scheme of amalgamation, in the strong hope that they may be able to arrange with the Apothecaries' Hall of Ireland a scheme which shall include the Apothecaries' Hall with the two Colleges. The admirable argument of Dr. STRUTHERS was practically unanswerable, and was obviously accepted in this light by the great body of the Council. The unfortunate results which would follow from the existence of separate licensing bodies if the Colleges persisted in their refusal to allow the Apothecaries' Hall to unite with them were amply dwelt upon by the speaker, and he further showed that the Council had itself, in a communication addressed to the military authorities, expressed their opinion that the licentiates of the Apothecaries Society in Dublin are, as apothecaries, entitled to practise medicine in Great Britain and Ireland. Of the twelve speakers who followed Dr. STRUTHERS, not one could be said to adduce any substantial argument against his proposal. The College of Surgeons themselves were in favour of the amalgamation; it was only the College of Physicians that held aloof, and Dr. AQUILLA SMITH appears to have contented himself with statements to the effect that the College he represented disapproved of the proposed union. The only pertinent objection to the adoption of the resolution came from Mr. BRUDENELL CARTER, who, while fully sympathising with Dr. STRUTHERS' views, was unwilling to see the Council exceed its statutory powers, and recommend the adoption of a course which it was unable to enforce. Eventually the motion was adopted by a large majority, and it remains for the Irish Colleges to determine the final issue.

It is sincerely to be hoped the Colleges will take advantage of this further opportunity for the reconsideration of the question, and that they will learn from the decision of the Council that the Apothecaries' Hall are not likely to apply in vain for the appointment of assistant examiners should it be necessary for them to make such application to the Council. We would hope, further, that the English Colleges will learn, from the events of this week, that it would be well for them to regard as assured the appointment of the London Society of Apothecaries as an independent examining body should they continue to refuse to allow its union with themselves. Sir DYCE DUCKWORTH announced his ability to show that the controversy in England was not altogether comparable with that in Ireland. That there are some differences in detail we are prepared to admit; but the broad principles are the same, and will afford sufficient reason for the Council to arrive at a similar conclusion when the subject comes under their consideration. The only hope that can be entertained is that a golden bridge may yet be found by which opportunity may be given for the Colleges to retrace their steps. Dr. GLOVER forcibly showed that the desire to preserve the existence of the Apothecaries' Societies as examining bodies did not emanate from the Council, but was given by law, and that the duty which devolved upon the Council was to carry that law into effect. Of the intention of the Legislature on this point there can, indeed, be no doubt; and we would protest against "the battle of the shops," to which Sir HENRY ACLAND referred in his address, being further continued to the detriment of the profession.

The many reasons which exist for the adoption of the principle of unity have been so fully discussed in these columns that it is needless now to consider them further. If the corporations had been less desirous of their own welfare than that of the profession, there would be less urgency for the demand for a reconstitution of their governing bodies. But this demand has now been made, and will

Digitized by Google

receive fresh impetus if, in the face of the recent decision of the General Medical Council, the English and Irish Colleges refuse to modify their policy.

LAST week we referred in general terms to the subject of the influence of small-pox hospitals in London, to which so prominent a place is given in Dr. BUCHANAN'S last report to the Local Government Board on the proceedings of his department. It is sincerely to be hoped that this report will lead to some final decision as to the attitude of the Government towards metropolitan small-pox hospitals, and since the material which is so ably put together in it on the subject cannot fail to exert an important influence on medical and public opinion, we now recur to the matter in some detail.

The immediate cause of this report was the receipt from Mr. W. H. POWER of a further account of the influence of Fulham Hospital down to the end of 1884-85, that account showing once more that the use of that hospital for the reception of small-pox cases at times when that disease was about to assume epidemic proportions led to an excess of small-pox around the hospital, that excess being graduated according to the proximity of the houses to the institution. And this repeated experience is the more important because it has taken place in the face of every effort to remove the conditions by which infection might be spread along lines of communication between those inside and those outside the hospital. In spite of every possible restriction, the fact remains that houses within half a mile of the hospital have been attacked at three times the rate of those between half a mile and a mile of it, and at nearly four times the rate of the parts beyond. If Fulham stood alone, it might be possible, even in the face of the overwhelming statistical evidence which has been repeated year after year, to express some doubt as to whether this fatal influence was a necessary result of these London small-pox aggregations; but similar evidence as to the effect of the other metropolitan small-pox hospitals has, during recent years, been flowing in apace, whether it come from Deptford, Stockwell, Homerton, or Hampstead, or, again, from Highgate or West Ham. As Dr. BUCHANAN points out, metropolitan and registration districts exhibit a change of rank, *qua* small-pox, when a small-pox hospital is established in them, this change of rank varying, again, according as the hospital is used or not. Thus Hackney and Camberwell, which for twenty years stood high in rank in regard to the freedom of their inhabitants from small-pox deaths, needed but a small-pox hospital in their midst to be relegated to a place among the worst districts. The Registrar-General, in his annual summaries for 1881 and 1884, basing his argument on registration districts, tries to console the sufferers from small-pox in these special areas by telling them that though "that district which contains the small-pox hospital may be the one which derives on the whole the least benefit from it, or rather which has the benefit conferred by it counterbalanced by some small disadvantage," yet the absence of a hospital may be a greater evil by leading to a disinclination to use it. And, indeed, using for this purpose groups of registration districts, he lays it down as "probable" that those districts are worst off which neither have hospitals of their own nor make use of the hospitals outside, whereas those districts are best off which have no hospitals within their own areas, but make use of hospitals outside their borders. So, after all, those who suffer do so for the public benefit. This seems the only crumb of comfort which Dr. BRIDGES can provide in the report to which we referred last week. But unfortunately Dr. BUCHANAN'S inferences are based on the experience of definite circular areas round the hospitals themselves, whereas the Registrar-General's "probable" inferences are based on districts which, as Dr. BUCHANAN shows, have no fixed relation to hospital areas, and as such should not for a moment be compared with Mr. POWER'S areas.

But, leaving these special areas, Dr. BUCHANAN next considers the small-pox death-rate all over the metropolis, and he compares this with that prevailing in the provinces. Both in London and in the provinces generally there have been improvements in vaccination, and in both the small-pox mortality amongst children has in consequence been reduced below any former experience. But in the provinces the general small-pox death-rate has also been greatly reduced since the European epidemic of 1871, whereas in the metropolis there has been no such reduction. In fact, although before 1871 the London small-pox death-rate "only once reached the double of the provinces, it has in the last two five-year periods been maintained at a point sixfold and sevenfold that which has affected other parts of England." Taking a long group of years, from 1850 to 1874, the mean annual small-pox rate per million would be some 380 in the metropolis and 225 for the provinces; for the period 1875-84 it has been 268 in the metropolis and only 41 in the provinces. Some "new factor has plainly come into operation." Indeed, this changed attitude of London towards the provinces dates from the time when London, and not the country, became plentifully supplied with hospitals for small-pox, which, when in use, have again and again caused an excess of disease about them, this excess having amounted to a threefold incidence of small-pox upon the three nearest square miles as compared with its incidence on the remainder of the circumjacent districts.

The Royal Commission on Small-pox and Fever Hospitals believed that thirty or forty acute cases of small-pox might safely be treated in each of the metropolitan small-pox hospitals. Mr. POWER has shown conclusively that the evil influence of these hospitals can be, and has been, exerted with a much smaller number of cases, and it is obviously this influence which is largely contributing to maintain small-pox as an endemic disease in our midst, whilst it is disappearing elsewhere.

The closing paragraph of that portion of the report which deals with this subject of the diffusion of small-pox urges action on the part of the Metropolitan Asylums Board towards reducing the chance of spreading infection, such as was indicated by the Royal Commission. That Commission had taken into consideration Dr. BURDON SANDERSON'S scheme of a hospital so contrived that it should be artificially ventilated, and that its air should, after passing through the hospital, be subjected to a high temperature for the purpose of destroying its dangerous qualities before it was discharged and they distinctly place amongst their "practical recom-

Digitized by Google

mendations" one which advocates the adoption of this system, which they "fully believe" might be devised. But as yet nothing has been done in this direction. Surely here is a line of action which is plainly indicated, and we trust that all who have influence with the Asylums Board will press its adoption on them, for the only other alternative seems to be the entire abandonment of small-pox hospitals, at least in populous districts.

CREMATION is rapidly making its way in some civilised communities. Sensational objection to it is subsiding, and the gentler part of the creation, to whom not long since it was most objectionable, has, so to speak, come round to it with such effect that at a meeting of the Ladies Somerville Club, held a year or two ago, with one of the representatives of medicine in the chair, a resolution in favour of cremation was carried by a large majority. For many and sufficiently valid reasons we have been most careful in these columns not to favour cremation until we could see how it might be carried out, *cito, tuto*, and like the Latin poet, have felt our anxiety, "*tuta timens*," to the extent of fearing safety. For this there was abundant cause in one danger alone—namely, that men inclined to commit murder might find in the crematorium the easiest concealment of their guilt. At the same time we never doubted the value of cremation as a sanitary measure, and now that some of the more serious difficulties surrounding it are passing away, we are open to all fair discussion of its progress. In New South Wales the practice is gaining favour so freely that a Public Bill authorising cremation passed through the Legislative Chamber on August 5th for presentation to the Legislative Assembly, and has probably by this time become the law of the land. This Act is called the Cremation Act, 1886, and in its construction the word "crematorium" means a place furnished with apparatus in accordance with the provisions of the Act for the purpose of reducing the human body after death to its mineral constituents. Subject to the provisions of the Act, any person may establish a crematorium provided the site and place be approved by the Board of Health constituted under the authority of the Infectious Diseases Superintendent Act of 1881; but a licence must be obtained by the constructor, and be signed by the Governor with the advice of the Executive Council, and the burning of the dead body of any human being in a place that is not licensed is declared illegal. It is further rendered illegal to burn a dead body except under one of the following three conditions: (*a*) The receipt by the registrar of a certificate from some legally qualified medical practitioner, stating that such practitioner has been in professional attendance on the deceased for at least four days immediately prior to the day of death, and that the deceased died from natural causes; (*b*) a certificate of a legally qualified practitioner, after a post-mortem examination, that the deceased died from natural causes; and (*c*) a certificate from a coroner or justice of the peace who has held an inquest or inquiry as to the cause of death, conveying to the registrar that such cause has been inquired into and that no further examination is necessary. Some further rules of a more stringent kind are added relating to the responsibility of all who are concerned in carrying out a cremation. The registrar who improperly issues a "cremation permit" may be subjected to a fine not exceeding £500, or imprisonment for any term not exceeding two years. The relatives of a deceased person, such as a widow or next of kin, may prevent a cremation, unless the deceased has left an attested memorandum directing that his body shall be cremated, when it is the duty of the executor or administrator to see that the direction is duly carried out if there be a licensed crematorium within twenty miles of the place where the death occurred. As a protection against crime, there is a clause to prevent persons from giving, or joining in giving, certificates for cremation after the death of anyone in whom the said person has an interest or expectancy. There is also a clause by which the Governor, acting on the advice of his Council, may suspend cremation for sanitary reasons in the event of a great epidemic if the suspension be considered advisable; and there is another clause enabling the Minister of Justice to forbid cremation under certain circumstances. There are some other minor provisions in this Act which are important for local reasons, but which may be passed over here. We have presented the leading principles of the measure, and we are bound to admit that they are as sound as they are vigorous and effective. The provision which makes it impossible for anyone who has an interest or expectancy in a deceased person to obtain a "cremation permit" removes the one great objection, which we have always enforced, more efficiently than any other plan that has hitherto been proposed, and seeing that cremation is apparently already recognised by the law of England, we should be glad to see an Act passed in this country on the same lines; for it seems to be proved by recent cremations that there is no real obstacle to cremation in England in the present state of the law, and there was no real obstacle in New South Wales. But, with much common sense, our colonial brethren have preferred to proceed in this matter by virtue of an affirmative rather than a negative law, and they are unquestionably in accord with the spirit of the times in carrying out this principle. They have, in short made the law on a great sanitary question intelligible and fresh, so that everyone can understand it and act upon it. We must not conclude this article without claiming for the profession of medicine in the Antipodes considerable credit for the part it has played in the matter of cremation legislation. To one of our medical *confrères* in Sydney, the Honourable JOHN MILDRED CREED, who, in a speech exceedingly able and exhaustive, moved the second reading of the Bill in the Legislative Council of New South Wales, a tribute is due for the success which so far has been achieved towards bringing cremation into a legal and safe practice on the other side of the globe.

THE Presidential Address of the Rev. Dr. DALLINGER, F.R.S., who has had the distinguished honour paid to him of being for the fourth time elected President of the Royal Microscopical Society, possesses more than usual interest, for it treats of a series of experiments which he has conducted for nearly seven years without intermission, having for their object the determination of the extent of change of temperature to which the lower forms of organisms can be adapted by slow modifications. The problem which Dr. DALLINGER set himself to solve was first investigated

Digitized by Google

in placing various species of monads in a medium, the temperature of which, by an ingenious arrangement devised by Professor SCHÄFER, could be gradually altered at the will of the operator. The mechanism worked so well that the variations in temperature in the course of twenty-four hours were less than one-sixth of a degree Fahrenheit. Commencing at the normal temperature of 60° F., the first four months were occupied in raising the temperature 10° without altering the life history. When the temperature of 73° was reached, an adverse influence appeared to be exerted on the vitality and productiveness of the organisms. The heat being left constant for two months, they regained their full vigour, and, by very gradual stages of increase, 78° was reached in five months more. Again a long pause was necessary, and during the period of adaptation a marked development of vacuoles was noticed, which again disappeared when it was possible to raise the temperature still higher. The further history of the experiments presented practically the same features—long pauses, vacuolation, slow advance,—until at last the high temperature of 158° was reached, when the research was accidentally terminated.

It need hardly be said that great care, skill, and patience are required to conduct experiments extending over so long a period, but the interest attached to them is fully proportionate to the time and labour expended upon them. The capability of organisms to adapt themselves to their environment has hitherto been a postulate rather than a proved fact on the part of HERBERT SPENCER and DARWIN, and much still remains to be shown in regard to the influence such changes effect in the structure and composition of the body; but it must be acknowledged to be a striking fact that organisms which normally live and multiply at 65° F. and are killed at 140° F. should by gradual adaptation become capable of living at 158°, whilst on their return to their original temperature they die. The slowness with which cosmical changes of temperature occur, and the possibility that living organisms are capable of gradually adapting themselves to such changes, was not overlooked by DARWIN, but the difficulty that confronted him, with other naturalists, was the number of generations required to be investigated before any conclusions could be drawn in regard to the effects of change of temperature on the race under observation. Dr. DALLINGER has overcome this difficulty. The monads he examined incessantly multiply by division, the longest interval being four minutes. He must, therefore, have observed something approaching half a million generations of the organisms under consideration. This is not far short of the "countless generations" required, and it is surely a matter of great interest to find that at the close of the series the organisms are found to have undergone such modification either in their composition, structure, or functions, as to enable them to flourish under circumstances that at first proved fatal.

IT is proposed to form an Anatomical Society, which shall meet about four times a year for reading papers, and discussing subjects bearing directly, on Human Anatomy, Embryology, &c. The first meeting will probably take place in April.

Annotations.

"Ne quid nimis."

DEGREES FOR LONDON STUDENTS.

THE various methods which have been suggested for procuring degrees for London students have practically resolved themselves into two—viz., the professional as advanced by the Royal Colleges, and the academical as put forward in the programme of the promoters of a Teaching University. The authorities of the existing University are too much bound to the examination-groove and standard which they have inherited from its founders to be expected to make any but minor changes in their regulations, and Convocation (which must be consulted in respect of a new Charter) is too jealous of the teaching influence to allow any new step of importance to be taken, even if the Senate were inclined to take such an initiative. The Colleges are steadily pressing forward their movement, and will soon be in a position to make application to the Crown for permission to grant degrees under their joint authority and regulation. We are sorry, however, to have to again urge the Association for Promoting a Teaching University in London to put forward its views quickly and in some authoritative manner. It is evidently at the crisis of its existence. The small attendance of members at its general meeting shows that its protracted deliberations, conferences, and waitings on other bodies have wearied many of its members, and a large secession of others may be expected if something earnest be not soon undertaken. The teachers in the Arts and Science Faculties of University and King's Colleges, who constitute the largest proportion by far of the Association and its executive committee, must agree at once on some combined line of action, if they wish to be credited with any real desire to form the academic side of a new university, and to shape the movement in that direction. The Colleges will apply to govern the professional faculty, and it will be entirely due to the supineness of the teachers in the literary and scientific chairs of London if the basis of the movement is not made sufficiently wide to embrace them also. The Colleges have a well-defined claim and a definite aim in view; the Association seems at present merely a collection of well-intentioned gentlemen with a far-reaching ideal of some great university before it; but the ideal does not yet appear to present itself to all the members in the same light. This want of agreement will merely lead to obstruction towards the Colleges, and be no gain in any other line. It is imperative, therefore, that the Association should take some tangible step at once or quietly dissolve. The teachers at the Bristol School of Medicine are alive to the necessity of prompt action, and will either oppose or assist the Colleges, according to whether residence in London be made imperative in the schemes, or whether the provincial schools, not affiliated to a university, be included in the application. At present, the report of the delegates leaves this to the discretion of the future managing body.

MILK EPIDEMIC OF TYPHOID AT YORK.

THE epidemic of typhoid fever in York, the prevalence of which we recorded a short time since, has been made the subject of a very elaborate report by Mr. S. W. North, medical officer of health to the city. York has a system of compulsory notification of infectious diseases, and under it 243 cases of typhoid fever were reported during 1886, 29 terminating fatally. Of these 243 cases, 210 came under notice during the last four months of the year, and the great incidence of the disease was in the Micklegate district, where, subsequently to Oct. 16th, no less than 119 cases occurred. In this district there are three dairies, each of which was, before the outbreak, in the habit of receiving

Digitized by Google

milk from a dairy-farm at Osbaldwick. One of these dairies had used no other milk than the Osbaldwick supply; another mixed the supplies; and a third, the Cleveland Dairy Company, kept their several sources, as a rule, distinct. Considerable suspicion attached to this Osbaldwick milk, and hence Mr. North visited it. He found that the owner had been ill with some fever, and that his wife was then in bed with a similar disease; and he gives it as his opinion that the whole family had suffered from typhoid fever. The symptoms described are not sufficiently detailed to convey a decided opinion on the subject, but Mr. North's conclusion was doubtless founded on sufficient data. The dairy pump was found to have a privy on one side, and an open ashpit on the other, together with other conditions that ought never to prevail at a dairy-farm. The analysis of the well water did not prove much, but since typhoid excreta can be purposely mingled with water without causing special suspicion on the part of the chemist, this goes for little. But the slops and excrement from the house had gone into the ashpit or privy, or on to a slop stone near the pump, and it is added that "the arrangements of the premises and the habits of the people are such as to render any mode of contamination possible." The whole course of this milk through the tradesmen taking it and on to the public is discussed at length, and, by way of additional danger, it was found that, as a result doubtless of the use of the infected milk, there were on the Cleveland Dairy Company's premises two unreported cases of typhoid fever, and this whilst the manager was passing from the sick room of his children to distribute the milk to his men and to the shops. Between October 16th and December 18th a total of 168 cases were reported, and of these 111 are proved to have used the suspected milk. An Inspector having secured a sample of this Osbaldwick milk, it was stated to contain 10 per cent. at least of added water. And taking the three dairies distributing this milk, whether alone or mingled with other milk, it was found that 42·4, 38·5, and 21·7 per cent. respectively of their customers were ill with typhoid fever. In confirmation of this view as to milk infection, cases are cited showing how the disease picked out of families, not otherwise exposed to the infection through the use of milk, single individuals who had used it; and in one charitable institution, where only one out of forty-seven took the fever, the single case was that of the only child who had milk in an uncooked form. But all the typhoid fever in York has not been due to infected milk. It will be remembered how serious an epidemic took place in the autumn of 1884, and from what Mr. North says it is clear that, notwithstanding the severe lessons which the city has had, it still remains a town specially adapted to favour the spread of such an infection when once received into it. It is essentially a midden town, several hundreds of these structures having more than one privy in connexion with them, and their cleansing is greatly neglected, such work being mainly done at the discretion of the inhabitants. Then, again, the sewers are largely liable to deposit, and only under special circumstances and in limited areas are they either flushed or ventilated; they are also blocked by back-water in flood times. The street gullies and old sewers also admit of leakage of contents. Such an array of conditions favourable to enteric fever may well account for the fact that the disease is endemic in the city. But it is unfortunately supplemented by the suspicious circumstances attaching to its water-supply. Mr. North does not credit it with any share in spreading this epidemic, but its use involves, as we pointed out last week, a dangerous experiment on human lives. We hope that we may soon be able to report some substantial progress towards removing the dangerous conditions to which we have adverted, and which Mr. North has more than once brought prominently before the Town Council.

THE VOLUNTEER MEDICAL SERVICE IN PEACE AND WAR.

DR. W. P. MEARS has just been lecturing at Newcastle-on-Tyne on the Volunteer Medical Service, and his lectures have created much interest there. He shows that the Medical Department is almost in the same condition as it was in 1859. One surgeon only is carried on the establishment of each corps, however large it may be, even where, as in Edinburgh and Cardiff, there is an administrative battalion of 2000 men. The surgeon, Dr. Mears points out, has no duties laid down for him beyond attendance at ranges and in camp. He is not responsible in any way for the physical fitness of recruits, the sanitation of drill-sheds or corps buildings, for the sites and surroundings, the food, water-supply, or drainage of camps. His interference in such matters, unless asked for courtesy sake, might not improperly be considered impertinence, and his presence (personal considerations of course aside), except in an ornamental capacity, is apt to be thought of as a necessary inconvenience. He has nothing to do, does not know where to go, gets in everybody's way, and, as Dr. Mears points out very forcibly, is thus more likely to prefer the social to the military duties of volunteering. He is not even required to pass an examination, and his optional examination is more or less a form. Until last year he could not, like other officers, go to a school of instruction where alone he could learn anything of military medical work, and permission was granted him last year only on condition of paying his own expenses. That condition, we are glad to say, has just been removed. Dr. Mears, in his excellent lectures, fully points out the anomalous and indifferent state of the present Volunteer Regimental Medical Service, of which he is himself an active and enthusiastic member, and he makes some valuable and practical suggestions for its reform, which should have more than a local effect. We are pleased to see that he believes that the present unsatisfactory state of things is due to want of knowledge of medical requirements on the part of combatant officers, and not to want of good-will. In this view we entirely concur with Dr. Mears, and that much good might be done if the subject could be similarly brought forward in other Volunteer centres.

INDICATIONS FOR THE USE OF NITRO-GLYCERINE.

DR. TRUSSEWITSCH, in an instructive paper on the use of nitro-glycerine published in the *St. Petersburger Medicinische Wochenschrift*, points out that the value of this drug in various affections—angina pectoris, migraine, and neuralgia (which he describes as angioneuroses), as also in sea-sickness, some forms of anæmia, faintness, palpitation, and other diseases—depends upon the existence of an irregular distribution of blood, which condition may be inferred from a certain degree of pallor of the skin, especially of the face, often coexistent with a weak pulse and a small rigid radial artery, which frequently is situated at some depth. When, on the other hand, headache and neuralgia occur in patients with chronic congestion of the subcutaneous veins of the face, nitro-glycerine is to be avoided; and similarly it is of no use in asthma, when the face is reddened in consequence of emphysema. If, however, a pale face exists with angina pectoris, migraine, giddiness, shock, toothache, or sea-sickness, the best results may be looked for by giving nitro-glycerine. The regulating effect of the drug exercises an influence over the congestion of internal organs similar to that brought about by bloodletting; and in these congestions, whether of lung, brain, or kidney, when they are of a temporary character, the pulse is generally found to be slow and of low tension—a fact which, as the author remarks, is sufficiently well known in reference to the fever-free periods of acute

Digitized by Google

hyperæmia of the lung and kidney. Dr. Trussewitsch lays down as a rule that the condition of the pulse is the best indication for the employment of nitro-glycerine, and the most trustworthy guide as to the dose with which to commence the treatment. The smaller the radial artery is, the more rapidly it dilates under the action of the drug, and the less the secondary effects proceed; on the other hand, the fuller the pulse with a distended radial artery, the less it is affected; and finally, the softer the artery, with a weak pulse, the greater the secondary, and the less the general, effects. Single-drop doses of the 1 per cent. solution are sufficient in cases of small pulse, but with a full pulse it will be found that the full effects cannot be produced with less than two-drop doses. When there is a soft artery with a weak pulse, subnormal doses only should be given—a quarter to half a drop. After the trial dose is given, the patient's sensations of pulsation and pain in the head, as well as the distension of the radial artery under the finger of the physician, will be the guides for increasing the dose. The author finds that the best modes of administering nitro-glycerine are the simple dropping of the solution on the tongue, and by means of tablets; much less satisfactory results were obtained when given mixed with water.

THE BIRKENHEAD AMPUTATION CASE.

On Jan. 28th an inquest was held at Birkenhead by Mr. Churton, coroner, touching the death of Mary Murray, fifty-four years of age. The facts of the case were very simple. The deceased was subject to fits. On Jan. 5th she was found lying on the floor, with a shawl which she had round her neck on fire. Whilst she was an in-patient at the Borough Hospital gangrene of the foot and leg set in. The mortification spread so rapidly that it became necessary, in order to save the woman's life, to amputate the limb without delay. A messenger was sent to the husband to seek his consent to the operation, but on its being found that an answer could not be obtained for three hours, the staff of the hospital decided not to wait but to amputate at once. This was accordingly done. At the inquest the husband of deceased complained that he received no intimation that an operation would have to be performed, and one of the jurors considered "that great laxity existed on the part of the doctors in not consulting the deceased's relatives with regard to the operation to be performed." It might possibly be contended that legally an assault had been committed upon the deceased in that her leg had been amputated without the husband's consent; but such a charge would fall to the ground inasmuch as the woman was taken to the hospital to be treated for her injuries, and that, too, without any limitation or definition of the kind and extent of such treatment. Had it not been for the burns we doubt if the gangrene would have set in; and as, therefore, on this assumption the burns constituted the *causa causans* of the death, we maintain that the authorities were within their rights in doing whatever they deemed necessary to relieve suffering and to save life. Yet there is a general understanding that where any serious operation, as one perilous to life or involving mutilation of the body, becomes necessary or advisable, the immediate relatives of the patient shall, if possible, be made aware of its intended performance. Now, considering the extremely rapid course of the gangrene in this case, we are of opinion that had the Birkenhead surgeons waited for three hours they would have been guilty of dereliction of duty; for their first duty was to ward off impending death, and how could they be said to be doing so if they allowed the disease to progress for hours merely because they had not obtained the husband's sanction for amputation to be performed? It is just to suppose that so serious an operation was not anticipated by the magnate in charge, or he would have got provisional permission for its performance. In a still more recent case within our knowledge the husband refused to allow the gangrenous limb of his wife to be removed. Such refusal, we imagine, would make one answerable for being a party to acceleration of the death, in the same way that the "Peculiar People" are amenable to the law for neglecting to call in medical aid where it is by professional and common consent avowedly necessary. The coroner complained of the house-surgeon not giving notice of the death, but the latter gentleman replied that, believing death to have been due to natural causes, he did not think such notice necessary. We cannot help thinking, however, that where any kind of violence has been sustained shortly before death, it is well to give the coroner an opportunity of holding an inquisition if he deems it advisable, even if the medical man who attended deceased believes that the injury had nothing to do with causing the death. Where a patient, fifty-four years of age, sustains burns and is subsequently attacked by gangrene of the leg, it may be very difficult to say with certainty that the gangrene arose independently of the burns.

CATHETERISM OF THE AIR PASSAGES.

THE introduction of a catheter into the larger air passages, for the purpose of local medication or mechanical dilatation, or to obviate recourse to tracheotomy, has been much facilitated since the introduction of cocaine into laryngeal surgery. A paper recently read before the Medical Society of the Charité Hospital at Berlin by Dr. Landgraf, clinical assistant (*Berl. Klin. Woch.*, 1887, No. 5.), illustrates the ease with which the procedure is effected. He described a case presenting symptoms of stenosis of the left bronchus; the symptoms, which had gradually increased in severity, dating over two years. When admitted into the hospital last July, the patient was liable to dyspnœal attacks; and physical examination led to the above diagnosis. The constriction was at first thought to be due to compression, a view which was borne out by the presence of a small area of dulness over the manubrium sterni and to its right. There was no evidence that this was due to a tumour arising in the bronchial glands. The long duration of symptoms negatived the existence of a malignant tumour, and the absence of bacilli in the sputum set aside the notion of tubercular disease. Aortic aneurysm was more probable; but this diagnosis lacked confirmation, the only positive sign being the area of dulness. It was therefore thought to lie between syphilitic stricture (the patient had contracted syphilis twelve years previously) and aneurysm; and, since the former gave a more hopeful prognosis, the patient was placed under anti-syphilitic treatment. But the dyspnœal attacks increased in frequency, and measurement of the chest showed a diminishing capacity of the lungs. Further, an examination made at the beginning of October revealed what was thought to be a membrane deep down in the trachea. This appearance supporting the endo-bronchial character of the stenosis, it was resolved to resort to catheterism. The larynx was anæsthetised by a 20 per cent. solution of cocaine, and a 10 per cent. solution was injected into the trachea. The catheter was easily passed to a distance of 28·5 centimetres from the teeth (found subsequently to correspond to the tracheal bifurcation) without meeting any constriction. The catheterism was repeated at intervals, and on several occasions to a depth of 35 centimetres, with a view to traverse the left bronchus. The measure produced so much relief that at the end of the month the patient was well enough to leave the hospital. Unfortunately the diagnosis of stricture, which had been apparently confirmed by the relief of the symptoms, proved incorrect; for in a few weeks he returned, having had a severe asphyxial seizure, and shortly after died. The

Digitized by Google

cause of the stenosis proved to be—what is by far the most common cause of such a condition—an aneurysm of the aorta, which compressed the left bronchus. The condition which was mistaken during life for a membrane was an anæmic part of the right wall of the trachea. Although during life some irregularities in the mobility of the vocal cords were observed—on one occasion the right cord moving less on respiration and phonation, and on another the left cord appearing immobile in middle line,—yet the dyspnœal attacks could not be referred to involvment of the vagus. They must have been due to the compression of the bronchus, for they disappeared directly the narrowing produced by that compression was mechanically relieved. Dr. Landgraf fully recognised the danger of resorting to such mechanical dilatation in aneurysmal cases, and he would hesitate to catheterise in any case in which aneurysm could be suspected. Nor is it quite easy to account for the great relief temporarily afforded by the measure in this case. The valuable point learnt from it is the ease with which the air passages can be catheterised with the aid of cocaine, thus affording means to relieve strictures, as well as to apply remedies locally to ulcerated surfaces on the respiratory tract.

"VENT—NOT VENTILATION."

IT is encouraging to find that the particular, if not peculiar, views of the sewer-air and drain-ventilation question, which have for many years past been put forth in these columns, are at length becoming popular—at least, so far popular that a leading sanitarian is pleased to adopt and enforce them. In his lecture on "The Laws of Nature in relation to Health," recently delivered before the Hertfordshire Natural History Society, Professor Attfield, F.R.S., denounces the absurdity of ventilating at a low level close drains, and shows clearly enough what ought to be evident to every common-sense observer—namely, that (1) directly in proportion as we make "openings" at a low level for the escape of air from sewers do we return to the open ditch system; and (2) that there is really no need for the ventilation of drains—it is only a vent to avoid back-pressure in the drain that is required. These two propositions should not need even to be formally stated. It goes without saying that to make in any pipe which is designed to carry away a noxious material such an opening as will admit of the escape of its contents, whether solid, fluid, or gaseous, must needs be to destroy its character as an apparatus for the removal of offensive matter. As well put an air-tube in the cover of a close-stool as ventilate a drain. Who first evolved the absurd notion that drains should, or *could with impunity*, be ventilated by openings at a low level we do not know. That there must be some sort of safety-valve for the escape of small quantities of air or gas when over-pressure occurs from back-flow or the sudden influx of storm-water cannot be doubted. If no such provision were made, the foul gas in the sewers must be forced back through the water-traps into our houses. The obvious mode of supplying the air-vents necessary is to erect pipes at suitable points reaching to high levels, and there affording a way of escape for air or gas in the drain at a safe distance from windows and chimneys. The notion of ventilating drains for the sake of ventilating them is so absurd that it can be compared to nothing but a special provision for the dissemination of pestilent gases and vapours in the atmosphere, and only the most perverse ingenuity could be supposed to intentionally and consciously propose the construction of openings into drains on the level of streets, and in the proximity of houses and thoroughfares. Professor Attfield's perspicuous and attractive mode of presenting the facts in his recent lecture is much to be commended, and we gladly welcome him as an advocate in a cause in which we are much interested.

AN OBJECTIONABLE "PLEBISCITE."

IT is greatly to be regretted that an enterprising contemporary could not, in the fertile ingenuity of its resources, discover some less objectionable subject for a prize than that which it recently proposed as a "timely plébiscite to its readers"—namely, the mention of names under the following extraordinary headings: (1) "The best doctor of all," (2) "the best ladies' doctor," (3) "the best surgeon," (4) "the best dentist," (5) "the best-managed hospital," (6) "the best watering-place for convalescence," and (7) "the best nursing establishment." "The usual prizes of £2 and £1 will be given to the two competitors whose coupons agree most nearly with the opinion of the majority." A plébiscite such as this can but be most repulsive to the feelings of the medical body as a whole, as well as of those selected. It is a grievous annoyance that practitioners should be subjected to freaks like this. The vagary to which we now direct attention is probably without its equal. "The winter," says the evening paper referred to, "is the doctor's harvest time ..... During the bitter winter months few of us escape the doctor's clutches, and there are few households in the metropolis to which he is not called." Upon this ground the plébiscite is regarded as "timely." Whether our contemporary thinks the "bitter winter months" are past and this is the time to return thanks for the blessing of a good doctor, or if he looks forward with dread to a wintry March and April, so that the opinions he proposes to elicit are likely to be presently applicable, we do not know; but it matters little to our immediate concern whether the gratitude which is to find this strange expression be for favours past or to come. Under any conditions, the scheme is a bad and offensive one, and we can only regret the adoption of a device so obviously objectionable.

THE GERMAN MEDICAL CONGRESS.

THE sixth annual German Medical Congress is announced to be held at Wiesbaden from the 13th to the 16th of April, under the presidency of Prof. Leyden, of Berlin. The following are subjects already notified: The Treatment of Phthisis, to be opened by Dr. Dettweiler (Falkenstein) and Dr. Penzoldt (Erlangen); Localisation in Cerebral Disease, by Professor Nothnagel (Vienna) and Dr. Naunyn (Königsberg); the Pathology and Treatment of Whooping-cough, by Dr. Vogel (Munich) and Dr. Hagenbach (Basle). Besides the foregoing set discussions, papers are promised on Pernicious Anæmia, by Dr. Lichtheim (Berne); on the Pathological Anatomy of Tabes Dorsalis, by Professor Rindfleisch (Wurzburg); on Experimental Epilepsy, by Dr. Unverricht (Jena); on the Physiological Import of Migrating Leucocytes from the Tonsils and Lingual Glands, and on Chyluria, by Dr. Rossbach (Jena), who will also describe a chair he has devised for aiding respiration (*Athmungsstuhl*) in cases of emphysema and asthma. The secretary of the Congress is Dr. Emil Pfeiffer, of Wiesbaden.

ON THE ETIOLOGY OF THE UTERINE SOUFFLE.

WEHMER contributes to the *Centralbl. f. Gyn.*, March 13th, 1886, an interesting case in which the seat of origin of the ordinary form of uterine souffle could be clearly and experimentally demonstrated. A. Z——, multipara, pregnant nine months; abdomen very pendulous. The recti muscles were so widely separated as to leave below the umbilicus an interval of twenty centimetres (eight inches) between one another. In this interval the abdominal walls were extremely thin and translucent, so much so that through them a large pulsating bloodvessel could be seen on the left side running in the uterine wall and followed for a distance of ten centimetres (four inches). On auscultating this vessel, a distinct

Digitized by Google

whizzing bruit was audible synchronous with the maternal pulse, and the movements of the arterial wall could be readily felt with the finger. Pressure with the stethoscope or the finger completely silenced the bruit. Anæsthesia also brought it to a standstill, owing probably to the coexisting fall of intra-abdominal pressure; the bruit returned when the woman regained consciousness. During the labour-pains the note of the souffle reached a higher pitch and became musical. After delivery it continued audible for two days with diminishing distinctness. Wehmer believes this to be the first case in which the seat of origin and the various circumstances affecting the souffle have been so capable of demonstration, and here they were so owing to the existence of an unusually large branch of the uterine artery.

INFANT MORTALITY AT WORKINGTON.

THE *Times* comments on the "remarkable report" of the medical officer of health of Workington, in Cumberland, and quotes the comments it contains on the extraordinary infantile death-rate, which is stated to have amounted in 1886 to 136·2 children under one year of age per 1000 registered births. This mortality is regarded by Mr. Lowe as due to a series of causes, and notably to tea-drinking, patent medicines of a "soothing" type, and to the neglect of children whilst their mothers are engaged at meetings of the Salvation and the Church Armies. The statements which the report contains as to scarlet fever, and the threat of resignation which Mr. Lowe commits himself to because he will not be a party to "wilful murder" if his advice as to school-closing should be disregarded, probably have reference to a fatality amongst children at the school age and not to young infants. The School Board, he alleges, "prefer to save money at the expense of human life," a statement which we assume, relates to the frequently experienced desire of School Boards to look with disfavour on anything which lessens the school attendance, and so interferes with the Government grant. But as to children under one year of age, we think Mr. Lowe bases his scathing condemnation of Workington on insufficient data, for at Workington the infantile death-rate under one year—that is, 136 per 1000—fell short of that for England and Wales during the same period, and indeed during any recent period. For the whole country the corresponding rate was 150 in 1886, 147 during 1885, and 149 for the ten years 1871-80. Whilst we have no wish to detract from efforts to reduce the deaths amongst infants in Workington, we feel bound to point out that the rate there experienced is by no means extraordinary. If Mr. Lowe had turned his attention to the 178 per 1000 rate in the twenty-seven provincial towns quoted by the Registrar-General, or to the 200 to 250 rate in some selected towns, we could have better understood the terms of his report.

BORACIC ACID AS A PRESERVATIVE OF FISH.

THE preservation of fish, and especially herrings, by boracic acid is a matter of considerable economic importance, and one which cannot fail to have an interest from a medical and hygienic point of view. The subject naturally divides itself into two distinct departments—the influence of the preserving agent on the fish, and the effect of fish so preserved on the human economy. As often happens in questions of the kind, accurate scientific data are not available for the discussion; so that we have to trust to *a priori* reasoning and to common sense. That boracic acid cannot improve the quality of the tissues of the herring as a food goes without saying, and we have the actual evidence of the senses to prove that its savour and appetising qualities are deteriorated by this method of preservation. That the acid used efficiently and in sufficient quantities will prevent septic decomposition may be granted, but this is hardly all that is required of a preservative of fish. From long experience we have learnt that preservation by common salt and by wood smoking is not deleterious, but we have yet to learn whether fish can with impunity be kept in boracic acid for a long period of time. However, in the absence of accurate experimental data, it is impossible to assert positively that minute doses of boracic acid can prove deleterious to the healthy action of any or all of the organs of the body, though the inference may fairly be drawn that the use of the drug can neither be truly preservative of all the qualities of fresh fish nor altogether innocuous to the physical welfare of man.

SCIENTIFIC TERMS.

IT has sometimes been questioned whether the use of Latin or Latinised Greek as the language of scientific nomenclature is not open to the accusation of pedantry. Some would prefer a system like the German, which to a large extent employs, besides the usual classical expressions, a set of names belonging to the native tongue. This plan has no doubt some value with a view to popular instruction; apart from this consideration it is needless and cumbersome. On the other hand, the revival of the dead languages for the same purpose has distinct advantages. Possessing a vocabulary copious, definite, and familiar to educated persons, they afford to all such the easiest means of arriving at a common understanding as to scientific facts. It cannot be denied, however, that the wish for precision does sometimes lead to wordiness. Natural history, botany, medicine even, but above all organic chemistry, can show instances in which a term has so excelled in lengthy conciseness of learned description that its fitness for general use is absolutely gone. Such terms in combination would almost constitute a new language in themselves. It is needless to say that their proper place is in purely technical records. Thus placed, they actually assist the expressions and understanding of the erudite. They have no convenient place in every-day life, and we find accordingly that as soon as they have to travel beyond the precincts of the laboratory they are superseded by terms which, if less fully descriptive, convey some definite idea in a simpler form.

THE MOSCOW MEDICAL CONGRESS.

THE second congress of Russian practitioners has just been held in Moscow (the first having taken place at St. Petersburg last year), and seems to have been a great success, the great hall of the University being crowded at the two general meetings by hundreds of medical men from all parts of Russia. It had been previously announced that the sections to which most prominence would be given would be those of Public Medicine, Pharmacology, Balneology, and Electro-therapeutics, and the Pharmacy and Pharmacognosis of Ophthalmic and Children's Diseases. General subjects were, however, by no means excluded, many burning questions connected with both medical science and medical politics being discussed. At the final general gathering, Professor V. V. Pashutin congratulated his audience on the increased number of members whom this congress had succeeded in attracting, there being no less than 1300, whereas last year there were only about 500. The number of papers, too, was double that which was communicated to the St. Petersburg meeting, being 200 against 100 last year. Remarking on the general interest of these papers, he mentioned as particularly valuable those on the treatment of phthisis, the various operations for stone, Cæsarean section and abdominal section, Pasteur's inoculations, the need of raising the level of pharmacists' education, the possibility of admitting properly educated women to

Digitized by Google

the examination for dispensers, over-pressure in schools, the want of revision of medical legislation, the definition of the position of medical experts in legal practice, &c.

MORTALITY IN PUBLIC LYING-IN HOSPITALS OF GERMANY.

DOHRN, in *Zeitsch f. Geb. und Gyn.*, p. 121, 1886, draws attention to the great diminution in the mortality of lying-in women which has taken place in the above-mentioned establishments since the introduction of antiseptics. He selected the period of 1874-83, since in 1874 antiseptics were scarcely used anywhere, while in 1883 they had become very general. The total number of cases of labour was 104,287, and 1429 women, or 1·37 per cent., died. The vast improvement indicated by this percentage will be clear on comparison with the statistics of previous years. Thus, in 1866, Lefort found the average mortality in the lying-in hospitals to be 3·4 per cent., while Winckel in 1869 calculated the mortality on 500,000 births to be 3 per cent. Even this great improvement, however, in lying-in institutions leaves their mortality far behind that of women attended in private practice; in the latter the percentage of deaths is only ·6 to ·7 per cent. Various influences contribute in bringing about this result: 1. The large proportion of primiparæ in public lying-in hospitals, puerperal fever being, as is well known, unusually common after a first confinement. 2. The clinical instruction given in public hospitals, which is invariably accompanied by special dangers in spite of every precaution. 3. The numerous complicated cases that are sent to such establishments. 4. The fact that many women are admitted who have been examined and exposed to septic infection before admission. Dohrn further investigated the question as to how the mortality was affected by the clinical use made of various lying-in hospitals, and he found that the mortality in those in which no instruction was given was ·56 per cent.; in those where midwives were trained, 1·13 per cent.; in those where midwives and students were trained, 1·42 per cent.; in those where students were trained, 1·90 per cent. This shows, as Semmelweiss pointed out long ago, that students, who are much in contact with septic matters, are a great source of danger to lying-in women, even more so than midwives. Dohrn is of opinion that the recent decreased mortality in public maternities is solely due to the introduction of antiseptics, and that the mortality will be low in proportion to the conscientiousness with which the antiseptic system is carried out.

TREATMENT OF HÆMATOMA OF THE EAR.

DR. A. LEBRUN, in a clinical lecture published in the new Brussels journal, *La Clinique*, says that after having tried various plans for the treatment of hæmatomas of the ear, including free opening as well as Follin's method of making a number of punctures, and having found them all very unsatisfactory, he has latterly injected iodoformed ether with complete success. For this two needles are inserted into the tumour at opposite points; through the larger one, No. 3 of Dieulafoy's aspirator, the contents are drawn off, the puncture being closed by means of iodoformed collodion. Then through the remaining needle, which is that of an ordinary hypodermic syringe, from fifteen to sixty minims of a solution of iodoform in ether, of a strength varying from 2 to 10 per cent., is introduced into the cavity of the tumour. This injection causes some pain, which, however, soon passes off. No dressing is required, and a complete cure results. In one case M. Lebrun twice injected a saturated solution of iodoform in ether without evacuating the contents of the tumour. This occasioned severe and prolonged pain, an eschar of the size of a half-franc piece formed, and although this healed, the process required more than three weeks. The comparatively unsatisfactory result in this case is considered by M. Lebrun to have been due to the escape of a large part of the first injection, and to over-distension of the tumour.

ANIMAL LYMPH.

A PARAGRAPH which emanates from the Central Press has appeared in many newspapers, to the effect that the Local Government Board have issued, or are about to issue, a circular letter enjoining precautions to be taken with regard to vaccination, and recommending a more general use of calf lymph. We disbelieve the latter part of this story. The Local Government Board have recently published the report of their medical officer, Dr. Buchanan, in which he states that as Dr. Cory "has previously established an identity between calf lymph and humanised lymph in the degree of their 'insertion success' when both are used in a fresh condition, so now he shows (at all events for English practice) that there is much less difference than at one time was believed to exist between the two kinds of lymph, in respect of the degree of success obtainable from them after keeping during ordinary periods of time." Thus, calf lymph may be relied upon to produce results similar to those of humanised lymph, but it would be disastrous if the use of stored calf lymph were to replace direct arm-to-arm vaccination. The reports of the Local Government Board have amply shown that direct vaccination arm-to-arm or calf-to-arm should be performed wherever this is possible, and if direct vaccination is replaced by the use of stored lymph, as would be the case if calf lymph were "generally" used, the protection of the population against small-pox would be greatly diminished, for the results obtained by the latter process would give an insertion success of some 20 or 30 per cent. less than direct vaccination.

THE JUBILEE YEAR AND THE HOSPITAL SATURDAY FUND.

A DAILY contemporary reports a public meeting in Bethnal-green to promote the collecting of voluntary contributions in aid of the metropolitan hospitals, dispensaries, and convalescent homes. The collection is to be by boxes in all conceivable places, to be spread over fifty days, and is to take the place of the annual demonstration and collection of the East-end of London in aid of the Hospital Saturday Fund. Two-thirds of the sum raised are to be given to the Hospital Saturday Fund, and the remaining third to the Working Men's Morley Convalescent Home near Dover. This is a Jubilee movement, but is scarcely to be distinguished from the ordinary Hospital Saturday methods. We repeat what we said last week and often before, that systematic weekly payments by the working classes should be organised by the Hospital Saturday Fund.

UNQUALIFIED ASSISTANTS.

ON the subject of unqualified assistants we continue to receive communications, urging two very sharply different views. According to one set of writers, unqualified assistants are an unmitigated evil and almost an imposition on the public. According to another, they are an old institution to be retained, if not defended. We have not further space for this controversy. The general conclusion in our mind is that the day of unqualified assistants is wellnigh over. A few old members of the class are to be pitied, and some of them are even to be respected for their abilities and character. Such men will still find employment—perhaps should find employment under the immediate eye of good practitioners. But their prospects and position will be increasingly unsatisfactory. Public opinion demands that

Digitized by Google

all men who practise medicine should be qualified, and the profession feels that it is injured by the competition of unqualified assistants. All young men who are shirking their examinations and threatening to drift into the position of unqualified assistants should take warning in time. If they cannot see their way clear to gain medical qualifications, they should abandon all thoughts of medical assistantship and take to other callings.

NEURASTHENIA — NOT HYSTERIA.

MR. HOVELL returns with unabated ardour in a pamphlet before us, published by Churchill, to his favourite occupation, that of defining the conditions of neurasthenia, and combating the theory that it is represented in the term hysteria, which he would like to see abolished from medical language. He has no patience with material views of the causation of such states, whether tending to locate the material injury in the nervous or the uterine system. He complains that the effect of shock, especially moral shock, has been much overlooked in this connexion, and would have us regard neurasthenia as essentially a psychological condition in which no lesion can be detected. He claims for such patients more patience and sympathy than he thinks they receive under the old theories of their disease. He admits the cures wrought by Dr. Weir Mitchell and Dr. Playfair, though he thinks the cases of the latter physician savour more of coercion than is desirable, considering that he is dealing with patients of the feminine gender. His guiding principles of treatment are to remove all causes of irritation and to build up the strength. The one point on which all seem agreed nowadays is the existence of a veritable weakness in such cases. This should be considered and treated. It is equally undeniable that some degree of firmness in the physician is beneficial, though this should never be allowed to exceed proper limits. A third point is that the uterus has no such special culpability in these cases as has been assumed, and that the use of the term "hysteria" as involving an exploded notion should be discontinued. Possibly finer researches in pathology than have yet been realised, or are even now practicable, may show positive physical lesions in many of these cases.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE following deaths are announced:—M. Bechard, Professor of Physiology and Dean of the Faculty of Medicine of Paris; he was also permanent secretary of the Academy of Medicine. Dr. Jos. Zit, *Privat-docent* of Children's Diseases in the Bohemian Faculty of Prague. Dr. F. von Jäger, former Chief of the Medical Senate, aged seventy-three. Dr. F. Sutkovski, Professor of Surgery in Kazan. Dr. Miltiader Weligelos, Professor of Midwifery at the University of Athens.

DAMP BEDS.

A CORRESPONDENT, "Traveller," in despair of finding any means which will prevent the use of damp beds, asks us to name an antidote which will protect the sleeper so unfortunate as to occupy one. A reply in the terms he suggests is for us, we fear, impossible. His question will be better answered if we follow the guidance of common sense than by an appeal to any purely professional dictum. In so far we differ from our correspondent, that we still believe in the preventive power of care on the part of travellers and hotelkeepers. Without this, indeed, no other remedy can have much efficacy. Neglect in this particular has been followed by the most serious consequences, and there is no detail in hotel management which more deserves the attention of the directing authority, or which, if its due execution were assured, would better repay the pains expended on it. The dampness of beds is usually in their sheets. Blankets and mattresses are not changed with every occupant, and are therefore less liable to this defect. Whenever, therefore, a traveller has reason to doubt if his bed has been duly aired, he should insist that the sheets be thoroughly warmed forthwith by hot bottles or some other mode of applying dry heat.

HERPES ASSOCIATED WITH LOCOMOTOR ATAXY.

IT is stated in *O Correio Medico*, of Lisbon, that there is now in the wards of the hospital of St. Sebastian of that city a patient suffering from locomotor ataxy, who in addition to joint affections as described by Charcot, and loosening of the teeth while quite sound, has developed herpes zoster, extending from the cervical to the lumbar region, the eruption spreading outwards in the directions of the intercostal spaces, and being accompanied by severe neuralgia and hyperæsthesia of the skin over all the region affected. A few previous cases of herpes associated with locomotor ataxy have been mentioned by Fournier, Charcot, and Buzzard, and by Portalier in his thesis (Paris, 1884). In all these, however, the herpes seems to have been developed in the pre-ataxic period. Similarly as to the falling out of the teeth which is also rare, Fournier only mentions one instance, and in this it occurred before the manifestation of ataxic symptoms. *O Correio Medico* refers to a thesis by Dr. H. Bonnieux (Paris, 1883) on this subject.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

AT the last meeting of the Society a resolution was adopted expressing approval of a scheme for amalgamation with the provincial Societies of Health Officers, as proposed by the President, Dr. Alfred Hill. A committee consisting of the president, ex-president, the treasurer, and the two honorary secretaries, was appointed to consider the details. The Council is about to report to the Society on the amendments which experience has shown to be necessary in the Public Health Act, 1875. Health officers who have found the Acts faulty in any particular should communicate at once with Dr. C. E. Saunders. This duty, it should be observed, is being undertaken by the Society of Medical Officers of Health, and not by the Epidemiological Society, as inadvertently stated in last week's issue.

BRIGADE-SURGEONS IN INDIA.

WE understand that the case of the Brigade Surgeons in India will shortly be brought before Parliament by Colonel Hughes-Hallett. We have repeatedly noticed the injustice done to officers of this grade by the denial to them of the advantages of pay and allowances which ought to attach to the rank. We trust that their claims may be so strongly pressed home upon the Government as to lead to an early redress of their grievances. Copies of the statement of these claims may be obtained by any person interested in the subject on application to Messrs. Holt, Lawrie, and Co., the Army Agents, in Whitehall-place.

THE CONTAGIOUS DISEASES ACTS.

THE Woolwich Board of Guardians was specially summoned last week to consider a letter received from the Portsea Island Union with respect to the spread of contagious disease since the suspension of the Contagious Diseases Acts, asking the Woolwich Board to appoint a deputation to co-operate with them in waiting upon the Local Government Board with a view to restoring the operation of the Acts. The chairman (the Rev. S. G. Scott, Rector of Woolwich) read a letter from the principal medical officer of the Woolwich district, in answer to a request for information which he had addressed to him. This letter gave ample evidence of the

Digitized by Google

lamentable results of the suspension of the Acts. The Board then questioned the relieving officers of the union, and they all, with a single exception, bore testimony of a similar character, as did likewise Mr. Boulter, the medical superintendent of the infirmary. One of the guardians, a local chemist, said that his "business experience" since the suspension of the Acts had furnished him with such overpowering evidence of the resulting evils, that he was now as strong an advocate for the restoration of the Acts as he had formerly been for their repeal. The Board unanimously resolved to give the co-operation asked for by the Portsea Island guardians.

HONOURS TO MEDICAL MEN.

THE Queen has been pleased to make the following, among other appointments, to the Most Eminent Order of the Indian Empire:—Sir George Christopher Molesworth Birdwood, M.D., C.S.I., Special Assistant in the Statistics and Commerce Department of the India Office, and Surgeon-General Benjamin Simpson, M.D., Sanitary Commissioner and Surgeon-General with the Government of India, to be Knights Commanders; and Thomas Beatson Christie, Esq., M.D., Medical Superintendent of the East India Asylum at Ealing, to be a Companion of the said Order. The Queen has also been graciously pleased to give directions for the following appointment to the Most Distinguished Order of St. Michael and St. George:—Surgeon Charles William Owen, C.I.E., to be an Ordinary Member of the Third Class, or Companion of the said Most Distinguished Order for services rendered on the Afghan frontier.

EXCISION OF CHANCRES.

DR. ANDRONICO claims to have entirely eradicated the syphilitic virus in four cases by excising the primary chancre. He believes that if the sore is situated in a locality such as the nymphæ or the prepuce, where excision is possible, and if the operation is performed within forty-eight hours, or at the very latest three days, from the first appearance of the chancre, success may be hoped for. The operation is, he says, contra-indicated if a longer time than this has elapsed or if the glands are enlarged.

RESPITE OF THE CONVICT THOMAS THOMPSON.

WE are glad to find that the representations we made as to the doubtful sanity of Thomas Thompson, sentenced to death at Durham for the murder of his child, have been so far confirmed by the experts to whom the question was referred that the Home Secretary has felt warranted in advising Her Majesty to respite the prisoner.

FOREIGN UNIVERSITY INTELLIGENCE.

Breslau.—The students have arranged a public presentation of thanks to Prof. Fritsch for declining an invitation to the chair of Midwifery at Leipsig.

Cracow.—Dr. Mikulicz, Professor of Surgery, who received recently an invitation to Konigsberg, at first accepted it, but subsequently withdrew his acceptance, preferring to remain in Cracow.

Dutch Universities.—The total number of medical students during the present session is 1254, Amsterdam having 462, Leyden 346, Utrecht 247, and Groningen 198.

Giessen.—Dr. H. Steinbrügge has been nominated Extraordinary Professor of Otology.

Halle.—The 14th inst. being Professor Krukenberger's 100th birthday, a grand assembly of his old pupils was held in his honour.

Italian Universities.—The total number of medical students at present is 5195. Of these, 2073 belong to Naples.

Nancy.—M. Spillmann has been selected for the chair of Clinical Medicine, and M. Alphonse Herrgott for that of Clinical Surgery.

Paris.—M. Guignard, Professor of Botany in Lyons has been appointed to replace M. Chatin in the École Supérieure de Pharmacie.

SIR HENRY THOMPSON has requested us to call attention to the unauthorised use of his name in widely circulated advertisements respecting Friedrichshall Water. He feels aggrieved, first, because he invariably refuses the use of his name to all applicants for recommendations in any form; and, secondly, because in this case he does not hold the opinion attributed to him. Nearly twenty years ago he named with approval, in a lecture at University College, the water in question—a period at which not more than two or three natural aperient waters were used in this country. Since that time several others have been imported, and he no longer endorses the original statement. The advertisers disregard this fact. There is never any clue to them in the announcements, or he would have sent an earnest protest against the practice. He has no other resource than to make one in public, and this we willingly afford him an opportunity of doing.

La Province Médicale (Lyons), referring to an American paper which had expressed an opinion that practitioners in France are less handicapped by public charities than in England or America, remarks that if the author fancies that French medical men are less put upon (*exploités*) than their American *confrères* he is quite mistaken. It is true that there are fewer dispensaries, but the multiplication of specialists and the opening of departments for patients to be visited at home fully make up for their absence. Then too, there are the mutual aid societies, whose system is to obtain advice, not gratis, but for very little.

ON Monday last the examinations for admission into the Army, Navy, and Indian Medical Services were commenced at the London University. Seventy-three candidates presented themselves for twenty-five commissions in the army, the same number for twenty-eight in the Indian service, and twenty-five for eight in the navy.

IT has been determined that the testimonial subscribed by past and present King's College students on the occasion of Dr. George Johnson's resignation of the Chair of Clinical Medicine shall take the form of a portrait, and Mr. Frank Holl, R.A., has accepted the commission.

IN our announcement in our last issue respecting the forthcoming meeting on behalf of the Hospital Sunday Fund on June 14th, it was stated inadvertently that the meeting would be held in the Guildhall instead of at the Mansion House.

THE Sanitary Registration of Buildings Bill to be introduced by Mr. C. C. Lacaita, M.P., will, we understand, be backed by Dr. Farquharson, M.P., Sir W. Guyer Hunter, M.D., M.P., and Dr. Cameron, M.P.

THE Queen has intimated her intention to become a patron of the National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square.

THE 150th anniversary of the founding of the University of Gottingen is to be celebrated next year.

Pharmacology and Therapeutics.

ERGOTINE IN INTERMITTENT FEVER.

DR. S. L. SAVITSKI, writing in the *Vrach* on the value of ergotine in the treatment of intermittent fever, remarks that the drug has been used with success in the treatment of many affections—e.g., by Vidal in prolapsus recti, by Hunt and Pepper in diabetes, by Saunders, Murrell, and Noakes in diabetes insipidus, by Allan for the cough in some lung affections, by Granzio in obstinate constipation, by Gauldmel in the night sweats of phthisis, by de Martini in spermatorrhœa, by Demange in some forms of typhoid fever, and by Girma in general paralysis. It has been also employed in chorea and in dysentery. The theory of its action in these diseases he does not pretend to expound, but he calls attention to the similarity of the action of quinine and ergotine. Both, he says, undoubtedly cause contraction of the uterus and the spleen, the effect of quinine on the uterus having been scientifically worked out in a dissertation published by T. T. Smolski in 1876, and that of ergotine on the spleen having been shown by Dobodchiki (*Vrach*, 1880) and by Semchenko (*Vrach*, 1883). This similarity led him to think that one of these drugs might serve as a substitute for the other, and he therefore made a large number of observations on the effect of ergotine upon the cases of intermittent fever occurring in the Lubinski regiment with excellent results, especially where an enlarged and tender spleen was present. He finds that a combination of ergotine with quinine acts very satisfactorily, and that in this way considerable quantities of quinine can be saved, as half the dose of quinine which would be required if given alone will suffice if combined with ergotine. The preparation of ergotine used was Bonjean's, the dose in chronic cases being about a grain three times a day.

SPARTEIN.

Dr. Gluziniski, in a preliminary note published in the *Przeglad Lekarski*, gives the results of some observations, both physiological and clinical, on the action of sulphate of spartein. Its main action is to slow the heart; besides this, it raises the blood-pressure. On cold-blooded animals it acts with a greater degree of intensity than on mammalia. The action on mammalia may be divided into three periods or stages, during the first and last of which the effects are more marked than during the second. Indeed, in some cases the heart is even quickened during the second period. This may be explained by the existence of some abnormality or pathological change in the irritability of the vagus or of the heart muscle. The reflexes are at first increased, afterwards diminished. Death occurs from asphyxia, and is due not only to the effect on the medulla, but to that experienced by the respiratory muscles. The therapeutic use of spartein is limited to the first stage of its action. Its value consists in the rapidity with which it acts. In some cases, within an hour after the first dose the pulse begins to improve, as well as the subjective sensations of the patient, and no irregularity is produced. Spartein has not so powerful an action as digitalis. It may, however, be useful in cases where the condition of the patient renders it unadvisable to wait for the more tardy effect of digitalis, and it may therefore be used as an adjunct to the latter drug, besides which it may be prescribed where circumstances exist which contra-indicate the use of digitalis.

EUCALYPTOL IN PHTHISIS.

Bouveret has employed hypodermic injections of eucalyptol in the treatment of phthisis. The daily dose of the antiseptic has varied from one gramme and a half to two grammes and a half. The duration of the treatment has been from fourteen to sixteen days. Sixteen cases of phthisis were treated by this method; six of the number had fever, and the remaining ten were without fever. There was rarely any local disturbance at the site of injection. It was certain that the antiseptic was absorbed; it could be detected in the breath, but not in the urine. Albuminuria was not observed as the result of the treatment. It is very doubtful whether the number of bacilli was altered in any way by the method of treatment. Sweating, as a rule, was diminished. Its chief effect is as a balsamic preparation on the bronchial secretion, which it influences favourably. MM. Perret and Chabbannes have made experiments with the 5 per cent. solution of eucalyptol, injecting a mixture of it with tuberculous matter under the skin of guinea-pigs. The general conclusion at which they have arrived is to the effect that the antiseptic is utterly insufficient to prevent the activity of the micro-organism that causes artificial tuberculosis.

HYDRASTIS IN UTERINE HÆMORRHAGE.

Dr. L. Göth has employed the tincture and fluid extract of hydrastis canadensis in various forms of uterine hæmorrhage, especially in disordered menstruation, metrorrhagia, hæmorrhage following abortion, and that occurring at the change of life. The best results were obtained where no organic disease existed, and in the climacteric hæmorrhages. Less satisfactory effects were observed in the menorrhagia of chronic metritis, and no effect at all was produced on hæmorrhage due to erosion of the os uteri or on the secondary hæmorrhage following abortions. The dose of the fluid extract used was twenty drops, and this amount was given several times a day.

HYPNONE.

MM. Mairet and Combemale have published a full account of their investigation into the physiological and therapeutical action of aceto-phenol or hypnone in the current number of the *Archives de Neurologie*. They are forced to conclude that it has no hypnotic action whatever; in this they differ from Dujardin-Beaumetz.

BISMUTH SUBIODIDE.

This is intended to replace iodoform. Iodine fused with bismuth forms bismuth iodide. Boiling the latter with water leads to the precipitation of the subiodide as a fine powder. It, like iodol, is said to be inodorous, and yet to be equally as effective as iodoform as an antiseptic.

HEALTH OF THE NAVY.

THE statistical report on the health of the Navy for the year 1885, which has just been presented to Parliament, shows, on the whole, a very favourable state of the sanitary condition of the force. The average strength afloat during the year was 46,670; the cases of disease or injury amounted to 1103 per 1000 of the strength, the deaths to 7·04, the invalided to 35·65, and the daily sick to 46·28 per 1000. These ratios are all considerably under those of the preceding year, and are also under the average of the last ten years. The marked reduction in the invalided, however, is probably due to an alteration in the returns under that head; for, if we understand rightly the remark on page xvii., "invalided" has hitherto included men sent home from foreign stations for change, as well as those discharged the service on account of disability; but on the present occasion only the latter are shown in the tables. We would suggest that the heading "discharged as invalids" would more accurately define the nature of the proceeding. Compared with 1884, the reduction in the admissions has taken place chiefly in paroxysmal fevers, rheumatism, syphilis, and injuries; in the deaths, in those from fevers and injuries; and in the invaliding, from fevers, debility, and injuries. The reduction in the death-rate has been well marked on the Home, Pacific, African, and East Indian stations. On all the others there has been an increase, though in none of them to any very marked extent.

The strength of the force afloat on the home station was 23,100; the cases amounted to 880, the deaths to 4·76, the invalided to 26·53, and the mean daily sick to 45·09 per 1000 of strength. These are all lower than the corresponding ratios in 1884. The reduction in the deaths, amounting to 3·47 per 1000, occurred chiefly in those from injuries, which were raised to an abnormal amount in 1884 by the loss of the *Wasp* on the Irish coast; in the present report only 10 deaths are returned in this class, as against 65 in the preceding year. Fifty-two cases of scarlet fever were reported, of which 35 occurred in the *Britannia* training-ship. The disease appears to have been brought by one of the cadets on his return from leave; he was attacked on Feb. 6th; on the 19th 10 cases were sent to hospital, on the 20th there were 8, and the others between that date and March 7th; they were all sent to the Cadets' Hospital on shore and recovered. The ship was cleared out and disin-

Digitized by Google

fected, and there was no recurrence of the disease. In June and July 10 cases of rötheln occurred on board the same ship. Twenty-two cases of enteric fever are returned on the home station, but 6 of them were contracted at Malta. Most of the cases occurred singly in ships; 4 only terminated fatally. Mumps prevailed to a considerable extent, 166 cases having been treated; of these 129 were on board the boys' training-ships. One of these, the *Lion*, also furnished a high proportion of cases of diseases of the respiratory system, including 38 of pneumonia, and the medical officer remarks that "damp decks, from too frequent wettings, with defective ventilation and overcrowding at times, have been, to a great extent, factors in the excess of this disease." A death from pyæmia occurred in the person of the junior medical officer of the *Ganges*, the result of an accidental puncture in the forehead by a suture needle while engaged in a post-mortem examination. On the Mediterranean station an average force of 5360 furnished 1342 cases, 8·02 deaths, 79·66 invalids, and 53·94 daily sick per 1000. The cases were considerably under, and the deaths 2·03 above, the ratios in 1884. The reduction in the cases was chiefly in those of rheumatism, syphilis, and diseases of the respiratory and digestive systems; and the increase in the deaths in those from continued fevers, diseases of the nervous system, and injuries received in action, the latter being from spear wounds in the attack by the Soudanese near Suakim on the 22nd March. There were 55 cases of enteric fever, with 12 deaths, in the squadron; of these 45 cases occurred at Malta during the last quarter—3 in October, 3 in November, and 37 in December. This outbreak was believed to have been the result of a contaminated water-supply, and it is stated that "one of the naval tanks—that, in fact, from which the water was at the time being taken for the ships—had not been cleaned out for a number of years, and the water, on being examined by the Government analyst, was found to contain a large quantity of albuminoid ammonia, and pronounced unfit for drinking." There seems good reason, however, to think that the water contamination was much more widespread, and that the disease was contracted, "not on board the ships, not by the drinking-water brought on board, and not by the stagnant air of the Grand Harbour, but by the impure water that the men drink when on shore on leave." The quality of the water from wells and the storing tanks is said to be most unsatisfactory, and enteric fever to have been prevailing as an epidemic among the troops and civil population at the end of the year. When it broke out in the fleet an order was issued by the commander-in-chief "that only condensed water was to be used in Her Majesty's ships until further orders." Works are in progress for an improved water-supply, and a new system of drainage is being carried out, which it is hoped will prove successful in reducing the prevalence of fever in the island. There were only 3 deaths from injuries, omitting those received in action already noted; one was by drowning, and 2 were from fractured skull by falls from aloft.

The force on the North American and West India stations averaged 2400; the cases were in the ratio of 993, the deaths of 5·0, the invaliding of 23·75, and the daily sick of 35·47 per 1000. These very closely correspond with the results of the preceding year, but contrast favourably with the average of the last ten years. The only disease requiring special notice was yellow fever, which appeared in Jamaica about the end of September. One case occurred in an engine-room artificer of the *Tyne*, and 9 cases with 3 deaths among the crew of the *Urgent* in Port Royal Harbour, contracted apparently on shore. No information is given as to any sanitary measures being adopted, nor does the *Tyne* appear to have been sent to sea—the usual course followed on such occasions. Of the 12 deaths which occurred on the station, 4 were from accidental drowning, and one from fracture of the skull by an accidental blow.

On the South-east Coast of America station, in a force of 510 the cases amounted to 1208, the deaths to 5·88, the invalids to 25·49, and the daily sick to 37·13 per 1000. The cases and mean sick were higher than in 1884, but all the ratios were under the average of the last ten years. Seven cases of enteric fever, with 2 deaths, occurred in the *Ready*, at Monte Video, between Feb. 4th and March 5th, evidently the result of a contaminated water-supply. The description given by the medical officer of the sources of supply and the condition of the storing reservoir is such as would warrant a prohibition to water ships there until some efficient steps have been taken to prevent contamination.

The Pacific station, from a force of 1710, had 1140 cases, 2·33 deaths, 32·16 invalided, and 46·07 daily sick per 1000 of strength. The cases and daily sick were higher, but the deaths and invaliding lower than in the preceding years, and the cases and deaths under the average. There was nothing in the returns which calls for special notice.

The African station, including the West Coast and Cape of Good Hope, had an average force of 1750. The cases were 1084, the deaths 4·57, the invalided 34·85, and the daily sick 36·13 per 1000 of the strength—all lower than in 1884, and under the decennial average. The cases of paroxysmal fever were less numerous than in the preceding year, but above the average; none of them terminated fatally. The disease was contracted chiefly on the West Coast. Quinine was given as a prophylactic, but does not appear to have been successful. Of the 8 deaths, 3 were the result of accidents.

On the East Indies station the average strength was 1900; the cases were in the ratio of 15·66, the deaths of 16·31, the invalided of 60·52, and the daily sick of 51·24 per 1000. These ratios are all much under those of 1884, and, except the deaths, are under the decennial average. Of the 31 deaths, 8 were by cholera, 4 from the *Briton* in Bombay Harbour, and 4 with the Field Force expedition in Burmah; and there were 7 deaths by drowning. The death-rate by disease, exclusive of cholera, was only 8·42 per 1000; diseases of the digestive system were the most fatal, giving a ratio of 3·68 per 1000.

In an average force of 3670 on the China station, there were 1556 cases, 9·26 deaths, 22·34 invalided, and 46·19 daily sick per 1000 of strength. There were 12 cases, with 2 deaths, returned as enteric fever, and 7, with 3 deaths, as typho-malarial fever, but the latter appeared to have been enteric. Eight of the cases, 4 of which terminated fatally, occurred in the *Audacious*, and 6 cases, with 1 death, in the *Cleopatra*. All but two occurred in officers, and were believed to have originated at Nagasaki. The exact source of the disease is doubtful, but it is suggested that it may "be accounted for by the fact that the officers made use of the hotels situated in the heart of the native town, and often dined there, these hotels being in a sickly state at the time." There were 10 cases of cholera, with 4 deaths, all of which appeared to have been contracted on shore at Hong Kong, Shanghai, and Nagasaki. "Cholera seems to be deeply rooted in all the Chinese ports, and must be expected to remain there until the value of sanitation comes to be appreciated in China." Diseases of the digestive system, especially diarrhœa, were unusually prevalent in the Japanese ports and at Hong Kong, the cases having amounted to 323 per 1000 of the strength.

On the Australian station the strength was 1420; the cases amounted to 1195, the deaths to 7·74, the invalided to 30·28, and the daily sick to 39·02 per 1000—all, except the daily sick, higher than in 1884, but under the average. Two-thirds of the deaths and upwards of one-fourth of the cases were returned under the class of injuries. Fourteen cases and 2 deaths of enteric fever occurred, of which 13 were contracted at Sydney and one at Brisbane. The disease at Sydney was believed to have been caused by defective sewerage and scanty water-supply. "Sydney still holds its position ... ... as the chief source of enteric fever in the squadron on the Australian station."

The Irregular Force, in which were included the Nile Expedition for eight months, and the Marines serving in Egypt and the Soudan for a little over six months, averaged 4850 strong. The cases furnished by it were 1385, the deaths 15·05, the invalided 40·82, and the daily sick 53·74 per 1000; one-third of the deaths were of men killed in action; of the 26 reported under this head, 17 occurred in the Nile expedition, consisting of 90 officers and men, and 9 at the zereba near Suakim, the former mostly by spear and sword wounds, and the latter by gunshot. Twenty-six cases and 12 deaths of enteric fever were returned; 5 of these, all fatal, were in the Nile expedition, and the greater part of the rest at Suakim and Alexandria. Twenty-one cases of heatstroke were recorded, of which 19 occurred among the men employed in Egypt and in the Nile expedition; only one terminated fatally. In addition to the 26 deaths in action, there were 13 by injuries, of which 6 were from fracture, 5 by drowning, and 2 by suicide.

The strength of the Royal Marine Divisions at headquarters, not included in the returns of men afloat, was 4880; the cases among them were 1293, the deaths 5·53, the

Digitized by Google

invalided 55·5, and the daily sick 62·42 per 1000 of strength, all in excess of the proportion in the preceding year. The admissions were much higher than among the troops serving in the United Kingdom, but the deaths and daily sick correspond very closely in the two branches of the service.

THE INFIRMARY FOR CONSUMPTION, MARGARET STREET.

WE regret to learn that through the apathy of the main body of the governors of the above institution, the homœopathic party were enabled at the special general meeting on Wednesday, to outvote by three the old body of governors, including the majority of the executive committee and medical staff.

After the notice convening the meeting had been read, the Rev. W. R. Mowll, M.A., moved a resolution to the effect that Drs. Jagielski and Marsh should cease from practising homœopathy at the Margaret-street Infirmary; further, that Dr. Jagielski should take his name from the Homœopathic Directory, and that Dr. Marsh should resign his appointment at the Homœopathic Hospital, or resign their appointments at this infirmary. This was seconded by Captain Hunter Baillie, and spoken to by Dr. Cholmeley, one of the consulting physicians, who in an able speech pointed out the incongruity of the present state of things, and said that nowhere in the United Kingdom was there an institution officered by a mixed staff of allopaths (so called) and homœopaths. He also stated that, should the resolution be lost, he and the six members of the staff who thought with him could no longer conscientiously retain their appointments, and read a letter from Dr. T. Hawksley, the senior consulting physician (who was too ill to be present) in favour of the resolution.

An amendment was moved by Dr. Dudgeon (a governor of only six months' standing), and seconded by Mr. D. Bryant (a governor of about three months' standing), which was spoken to by Drs. Jagielski and Marsh, and carried by twenty against seventeen.

Of the twenty who voted for the amendment in support of homœopathy, we understand that several have only recently become governors of the institution—that is, between three and six months, and since the question in dispute has been on the tapis. Of the seventeen who voted in the minority, all are old governors, and have for years given their time and services to the institution, and one of them, Mr. W. H. Baillie, for about forty years.

Lord Grimthorpe was in the chair, but voted with the homœopathic party, as did also Dr. Cooper Torry.

The seven gentlemen of the staff who have decided to resign are Dr. T. Hawksley and Dr. W. Cholmeley, the consulting physicians; Mr. F. Carr Beard, F.R.C.S., the surgeon; and Dr. Featherstone Phibbs, Dr. Julian Willis, Dr. Robert Walford, and Dr. Scudamore Powell, the visiting physicians. The majority of the executive committee also intend to resign—viz., the Rev. J. J. Coxhead, M.A., Rev. W. R. Mowll, M.A., Lieut.-Colonel Hollway, treasurer; Joseph Lott, Esq., solicitor; Captain W. Hunter Baillie, J. A. Pepys, Esq., and St. Leger Bunnett, Esq.

In again expressing our regret, we would warn other institutions by the fate of this one (an infirmary which has been of immense value to the suffering poor), so that they may be on their guard against this thin end of the homœopathic wedge.

THE SEAMEN'S HOSPITAL, GREENWICH.

THE annual meeting of the governors of and subscribers to this institution, which takes up the work carried on by the late *Dreadnought*, was held on the 16th inst, under the presidency of Sir Andrew Clark, Bart., M.D. The sixty-sixth annual report, which was read by the secretary, stated that though the institution had suffered severely during the great commercial depression, the committee had not been compelled to draw upon their reserve funds in order to make the income meet the expenditure. The number of patients treated last year was 2267, and of these 1452 were discharged cured and convalescent, 477 had been relieved, 87 died, and 194 remained under treatment at the close of the year. There were also 5359 out-patients during 1886, making a total of 269,782 patients treated at the institution since its foundation. Sir Andrew Clark gave an account of a visit of inspection he had paid to the hospital, and, commending its management, he urged its claims to the support of the charitable public. The report was adopted, and the customary votes of thanks brought the proceedings to a close.

PROSECUTION OF ORIGINAL RESEARCH IN EDINBURGH.

THE committee appointed to consider and report on the Prosecution of Original Research in connexion with the Royal College of Physicians, Edinburgh, have issued their Report to the President and Fellows of the College. The committee recommend (1) that the College establish and maintain in the neighbourhood of the infirmary a laboratory for the prosecution of original research; (2) that the College vote £1000 for the establishment of this laboratory, and, year by year, a sum not exceeding the third of the clear surplus of annual income over annual expenditure for its maintenance, including the payment of salaries. It is suggested that the laboratory be placed under the care of a curator and committee, with a scientific man as superintendent, at a salary of not less than £200 per annum, and an assistant, to reside on the premises, at a salary of £80; (3) that the laboratory be open without fee to Fellows and Members of the College, and to any investigator, on certain conditions; and (4) that the committee should be empowered, if sufficient funds be at its disposal, to offer yearly a medal and money prize (not exceeding £21) for original work conducted within the laboratory or elsewhere, the results to be embodied in essays to be submitted to the committee, and to be specially connected with medicine, therapeutics, gynæcology, and psychiatric medicine.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5788 births and 3453 deaths were registered during the week ending Feb. 12th. The annual death-rate in these towns, which had steadily declined in the preceding five weeks from 26·5 to 19·6 per 1000, further fell last week to 19·5. During the first six weeks of the current quarter the death-rate in these towns averaged 22·3 per 1000, and was 2·2 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 14·9 in Nottingham, 15·3 in Leicester, 16·1 in Derby, and 16·9 in Leeds. The rates in the other towns ranged upwards to 25·8 in Manchester, 26·9 in Liverpool, 27·1 in Wolverhampton, and 30·1 in Huddersfield. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding four weeks from 485 to 367, further fell last week to 340; they included 95 from whooping-cough, 77 from measles, 61 from scarlet fever, 43 from diphtheria, 32 from diarrhœa, 31 from "fever" (principally enteric), and only 1 from small-pox. No death from any of these zymotic diseases was registered last week in Derby, whereas they caused the highest rates in Norwich, Liverpool, and Huddersfield. The greatest mortality from whooping-cough occurred in Oldham, Sunderland, Huddersfield, and Norwich; from measles in Halifax, Bristol, and Huddersfield; and from scarlet fever in Birkenhead, Liverpool, and Sheffield. The 43 deaths from diphtheria in the twenty-eight towns included 17 in London, 4 in Liverpool, 3 in Birmingham, 3 in Manchester, 3 in Huddersfield, 2 in Portsmouth, 2 in Norwich, 2 in Oldham, and 2 in Hull. Small-pox caused 1 death in Manchester and 1 among the residents of London and its outer ring, but not one in any of the twenty-six other large provincial towns. Only 3 small-pox patients were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding five weeks from 731 to 364, rose again last week to 373, but were so many as 244 below the corrected average. The causes of 89, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical

Digitized by Google

practitioner or by a coroner. All the causes of death were duly certified in Leicester, Nottingham, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Bradford, Sheffield, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·7 and 19·8 per 1000 in the preceding two weeks, rose again to 22·0 in the week ending Feb. 12th; this rate exceeded by 2·5 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·0 in Perth and 14·4 in Greenock and Leith, to 24·7 in Glasgow and 27·4 in Paisley. The 550 deaths in the eight towns last week showed an increase of 55 upon the low number in the previous week, and included 28 which were referred to whooping-cough, 16 to measles, 14 to diarrhœa, 13 to scarlet fever, 3 to diphtheria, 2 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all 76 deaths resulted from these principal zymotic diseases, against 75 and 66 in the preceding two weeks. These 76 deaths were equal to an annual rate of 3·0 per 1000, which exceeded by 1·1 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 19 and 23 in the preceding two weeks, further rose last week to 28, of which 19 occurred in Glasgow, 3 in Aberdeen, and 3 in Paisley. The 16 deaths from measles showed an increase of 4 upon the number in the previous week, and included 12 in Glasgow and 4 in Aberdeen. The deaths from scarlet fever, which had been 16, 15, and 8 in the previous three weeks, rose again last week to 13, of which 7 occurred in Edinburgh and 4 in Glasgow. The 14 deaths attributed to diarrhœa showed a considerable increase upon recent weekly numbers, and included 5 in Glasgow and 3 in Dundee. The deaths referred to diphtheria and "fever," on the other hand, had considerably declined; 2 fatal cases of diphtheria were returned in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had steadily declined in the first five weeks of the year from 213 to 126, were last week 133, and were 11 below the number returned in the corresponding week of last year. The causes of 71, or nearly 13 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 28·2 and 29·7 per 1000 in the preceding two weeks, declined again to 27·3 in the week ending Feb. 12th. During the first six weeks of the current quarter the death-rate in the city averaged 30·8, the mean rate during the same period being but 21·1 in London and 21·4 in Edinburgh. The 185 deaths in Dublin last week showed a decline of 16 from the number returned in the previous week, and included 5 which were referred to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 4 to diarrhœa, 3 to whooping-cough, 1 to diphtheria, and not one either to small-pox or measles. Thus the deaths from these principal zymotic diseases, which had been 14 and 13 in the preceding two weeks, rose last week to 17; they were equal to an annual rate of 2·5 per 1000, the rates from the same diseases being 1·5 in London and 2·8 in Edinburgh. The fatal cases of scarlet fever, which had been 6 and 4 in the previous two weeks, were 5 last week, and the deaths from both "fever" and diarrhœa also showed an increase upon the numbers in the previous week. The fatal cases of whooping-cough and diphtheria corresponded with the numbers in the preceding week. The deaths both of infants and of elderly persons showed a decline from the numbers in the previous week. Six inquest cases and 5 deaths from violence were registered; and 51, or more than a quarter, of the deaths occurred in public institutions. The causes of 23, or more than 12 per cent., of the deaths registered during the week were not certified.

VENTNOR HOSPITAL FOR CONSUMPTION.—On Monday last, at the annual general meeting of the governors of this hospital, it was announced that the Duke of Cambridge would preside at a festival dinner at the Hotel Métropole on April 19th, and that in the summer Princess Beatrice would, on behalf of the Queen, open a new block of houses for twenty additional patients.

MEDICAL TREATMENT AT HOSPITALS AND DISPENSARIES.

To the Editors of THE LANCET.

SIRS,—I observe in the report of the proceedings of the Medical Attendance Organisation Committee that a resolution was passed calling "the attention of the governing bodies of hospitals and other public authorities to the necessity of some check on the indiscriminate provision of medical treatment at hospitals and dispensaries." Some years since this question forced itself on the notice of the managers of the Children's Hospital in Great Ormond-street, where the number of out-patients had become so large as to be entirely unmanageable. I have described in my book on Hospital Organisation[1] the manner in which this difficulty was dealt with, and so successfully that the number of out-patients, which had been 13,000 in 1874, was reduced to 9000 in 1876, and might, I believe, have been reduced still further, without inflicting real hardship on any deserving applicant. As the book is now out of print, I ask permission to state the details of the plan, which might, I think, with some possible alterations, be advantageously adopted in London.

The regulations were as follows:—All applicants were entered by the house-surgeon in attendance into two classes—viz., those of slighter ailments to be treated as casualties, and graver ailments to be entered on the register, and to be supplied with letters entitling the bearers to attend for a period of two months. The register and also the letters bore a record of the name and residence of the patient, as also of the occupation and weekly earnings of the parent; and no child whose parent was in receipt of more than 30*s.* per week was considered eligible for permanent treatment. These letters had to be submitted to the secretary or other officers of the Charity Organisation Society of the districts in which the patient lived, and to have the stamp of the Society in verification of the facts stated in the letters, before the patients were considered eligible for *permanent* treatment. Persons in the receipt of parish relief, and those whose income exceeded 30*s.* per week, were considered ineligible, but the medical officers were authorised on *purely medical grounds* to dispense with these regulations; they entering the reasons for so doing in a book provided for the purpose. A further regulation provided for the continuance of a patient for a longer period than two months, at the discretion of the medical officer.

It will be observed that in the first attendance every applicant was admitted without any question, and it happened very rarely that mothers came saying that they had no wish to attend permanently, but desired an opinion on some points concerning which they felt doubts or anxiety. Further, to provide against the exclusion of any on purely social grounds, the medical officers had a dispensing power wherever a case was of special medical interest, or where the treatment it required would be either costly or protracted. The regulations then applied, in reality, to those only who sought for permanent relief in ordinary ailments, and the aim was to deal with them as wisely, and at the same time as gently, as possible. The wife in almost every instance gave an answer, though often not an exact one, as to her husband's earnings, and it was at first attempted to control this statement by requiring that before presenting themselves a second time each letter should be countersigned by some householder, clergyman, city missionary, or other minister of religion. The regulation turned out a farce; the clergy of no persuasion cared to be guilty of the apparent unkindness of refusing their signature to a person asking for it merely to obtain hospital relief, and the small shopkeepers in a poor district did not dare to disoblige their customers. Theoretically, this test of fitness seemed to conciliate kindness and discrimination; practically, it was worthless.

At the time that the help of the Charity Organisation Society was sought for, though no longer on the medical staff of the hospital, I took an active part in its manage-

[1] On Hospital Organisation, with special reference to the Organisation of Hospitals for Children. London, 1877.

Digitized by Google

ment. Soon after my connexion with the institution ceased, the old system was once more resorted to; and the last report of the hospital shows a total of 14,281 new out-patients in the year 1885. This total represents an annual attendance of 85,686, on the assumption that each child attends six times, or a daily attendance of 279; of whom 46 would be new cases, deduction being of course made for fifty-two Sundays, Christmas Day, Good Friday, and four Bank Holidays. If we reckon that properly to investigate each case, new and old, three minutes is a reasonable time to allow, it appears that fourteen hours would be required; on dividing the labour among four, we find that three hours and a half must be devoted by each medical officer. It is needless to dwell on the time required to supply these patients with the necessary medicines, even though the dispensing arrangements were very good. The failure of the plan was at once assured when the original scheme was departed from, and in deference to the representations of the house-surgeons (who objected to be called on to put questions to the mother concerning their husbands' earnings or concerning any matter not purely medical) the preliminary inquiry at the hospital was given up. The officer of the Society was at once placed in an entirely different position when called on not merely to verify a statement, but to institute an entirely new inquiry for the conduct of which he had no data. He at once was placed in the offensive position of the relieving officer of the parish, who is supposed popularly to derive his name from its being his duty to refuse relief. The failure of the plan was secured by this apparently insignificant change, just as surely as the upset of a carriage by the removal of the lynch-pin. It would probably not have been difficult to entrust the preliminary inquiries at the hospital to others than the house-surgeons; but unfortunately the diminution of the number of out-patients was not seen with friendly eyes by many. The medical officers for in-patients did not like a scheme by which the field whence cases of medical interest were gleaned was diminished in extent; the subscribers sometimes objected to their letter of recommendation being submitted to inquiry; while the committee fancied that the larger the number of out-patients, the greater the claim of the charity to public support. A few complaints, too, were made by the patients themselves of the inquisitorial nature of the questions put by the agents of the Charity Organisation Society. Very few indeed of these complaints were well substantiated: while, to the best of my recollection, none were made during the time when the preliminary inquiries were made in the first instance at the hospital, and were referred for verification only to the Charity Organisation Society. The difficulty is one felt in France as well as in this country. My excuse for occupying so much of your valuable space is that I have seen no other plan proposed for dealing with it, and that, while it no doubt may be altered for the better, it at least attained the object for which it was started.

I am, Sirs, yours faithfully,

CHARLES WEST, M.D.,
Founder of the Hospital for Sick Children.

Harley-street, W., Feb. 7th, 1887.

"GENERAL HOSPITALS AND PARISH INFIRMARIES."

To the Editors of THE LANCET.

SIRS,—Allow me to make a few remarks in criticism of Dr. Goodhart's letter in your last issue respecting general hospitals and parish infirmaries. As the medical superintendent for nearly ten years of the largest of these infirmaries, I may perhaps be considered to have some slight special knowledge on the subject.

Dr. Goodhart's objections range themselves under the following heads:—1. It is an injustice to the ratepayer to have built, and to compel him to keep up, magnificent parish infirmaries. 2. That they do harm to the general hospital. 3. That they do injustice to the patients that are admitted within their doors; and he instances this result especially in surgical cases.

Take the first objection—that of injustice to the ratepayer (although, further on, Dr. Goodhart naïvely confesses he does not care much about him if his own hospital is not affected injuriously). I maintain the present system is not so. It is not expensive for the work done. The ratepayer has his work done for him much cheaper and quite as efficiently as at the general hospitals. I believe that the public has not much idea, after all, of how little is the actual cost for the maintenance of the sick poor. I have before me now the Local Government Board's "Return of Expenditure at the various Metropolitan Infirmaries," and I find that the total actual cost per head per week, including salaries, drugs, stimulants, and, in fact, every expense, is at St. Saviour's Infirmary 8*s.*, at St. George's, Hanover-square, 13*s.*, Lambeth 14*s.* 2*d.*, Kensington 14*s.* 2*d.*, and at St. Marylebone, which is admittedly, if I may use the expression, an extravagant infirmary, 15*s.* 10*d.* I have no means at hand of knowing myself the cost per head in the general hospitals, but I should imagine in most cases it much exceeds this. The reason why St. Saviour's is so low is that most of the labour is done by pauper help, and that there are many inmates who by rights should not be in the infirmary proper, but rather in the infirm wards of the workhouses.

The second objection of Dr. Goodhart I would reserve for the moment, simply remarking that from the point of view of the ratepayer, or of the sick actually in the infirmary, "doing harm to the hospitals" does not concern them.

Thirdly, that they necessarily do injustice to the patients, especially in surgical cases, I emphatically deny. If there is one branch of practice in which we have had the most satisfactory results, it is in surgery. I have not had leisure, for various reasons, during the last few years, nor have I time just at present, to publish my surgical statistics; but I hope to be able to do so at no distant date, and the results will be found to bear very favourable comparison with those of any general hospital. One would imagine that all surgical skill and knowledge is monopolised by *hospital* staffs! I don't believe it. I could tell more strange stories from personal experience of patients who have come under my care from general hospitals. One perhaps I may be permitted to quote. An old man who had fallen heavily on his side was carried to a certain hospital, complaining principally of pain in the left knee. For this the knee was carefully strapped and bandaged, and the patient sent home. The next day he was admitted here, when I found the knee absolutely uninjured, but there was a comminuted fracture of the left hip, with extensive bruising of the soft parts. On his death, a few days afterwards, from the effects of chronic bronchitis and severe fog, the diagnosis was fully verified at a necropsy, and the head and neck of the femur were found broken into four pieces! To anyone who has a bent for surgery, with a fair surgical education, it is absurd to suppose that he is not quite capable of undertaking any ordinary surgical operation. As for very rare or special cases, we seldom see them; these are too readily snatched up at hospitals; but, when we do come across such a one, some of us are quite able to undertake it, with, perhaps, some little extra assistance in the form of advice and opinion, which I have never found any difficulty in obtaining, even from some of the most eminent surgeons.

Surgical appliances are admittedly very expensive. Some certainly are, but I will not admit that they are always necessary, certainly not as a rule in parish infirmaries. I am often astonished, on visiting hospitals, to see the amount and quality of the dressings and appliances used. No wonder that under such conditions surgery is expensive and hospitals poor. Gauze dressings, gauze bandages, strapping, complicated splints, expensive drugs and appliances, are used with a reckless disregard to cost which is appalling to an onlooker. I can get quite as good results with some marine lint, a little Gamgee tissue, a very few layers of gauze, an ordinary calico bandage, and such cheap drugs as terebene, carbolic acid, iodine water, corrosive sublimate, and such-like. I have been answered by hospital surgeons: "Oh, yes, it is all very well for you, with healthy wards not crowded with surgical cases, to use simple appliances and dressings; but we cannot, with our surroundings." Well, this may be so, but I doubt it.

Dr. Goodhart says that the advanced surgery of the present day should always be a matter of free consultation. I entirely agree with him. I have always maintained that a patient has an absolute claim to it. I should like to ask him, however, how often amongst his surgical colleagues does this free consultation ever take place. When I was at the hospital I should say almost never, or "hardly ever." Look, on the other hand, at St. Bartholomew's, where there is a regular consultation of the staff once a week openly in the theatre. Could one find a proceeding more conducive to the welfare of patients and to the interest of the students?—not only to the benefit of the students from hearing the

Digitized by Google

various opinions expressed, but also in acquiring a notion of the forms and etiquette of consultation, a knowledge which cannot but be of great advantage in after-life. Again, on operation days at Guy's some years ago, one always saw two or three at least of the surgeons in the operating-room, assisting, at any rate, by their presence. Students liked to see them; it showed an interest in the hospital, it helped to develop an *esprit de corps* in one's *alma mater*. I remember how glad and proud one used to feel to be able to point out to strangers coming to operations, That is Mr. A., who wrote such-and-such a book, a great man on so-and-so; or, That is Mr. B., a very clever man—splendid fellow; why, he actually removed a kidney! And one felt a glow of pride in thinking what wonderful men *our* hospital possessed! Now, I regret to see that much of this has changed. The surgeon who is operating is generally without a colleague present; one may occasionally drop in apparently accidentally, look over the operator's shoulder, and walk out. Or operations are going on in three or four wards at once, and one never knows where any operation on the list is likely to be performed. This, I urge, is not just to the students, all of whom have a sort of pre-emptive right to an opportunity of seeing every operation, except of course those in which the patient might suffer from his presence, and it is, I am sure, a real grievance. As a matter of fact, the patients here have the advantage always of two opinions, and in very critical or doubtful cases one frequently calls for other advice in the persons of various consultants, whom I have always found most kind and willing with advice, and to many of whom I am much indebted. The proposition of having a consultant staff is more particularly because, as far as the medical officers are concerned, we feel we should not be dependent on the courteous kindness and gratuitous services of eminent medical men. It is only just and right that they should receive some fee, and that the pernicious system of continually enlarging the sphere of unpaid medical services should be avoided. Undoubtedly, there is a great deal of work in these infirmaries, and an increase in the medical staff is desirable. It must be remembered, however, that although we have a great number of cases, many of a serious nature, involving much time and attention, there is a large proportion of trivial ones, trivial at least as far as actual work in treatment goes, although perhaps not so in respect of pathological interest. A large proportion of our cases consists of chronic ulcers, chronic bronchitis, chronic gout, chronic rheumatoid arthritis, forms of paralysis in old people, and bedridden cases from senile decay. All these do not entail a large expenditure of time, so that to say that we have large general hospitals is not exactly correct. Two resident medical officers (and in every infirmary there are now two), not engaged in other practice and devoting their whole time to the duties, can get through a great deal of work.

I am afraid that I have already trespassed too much on your space, and will leave the questions as to the utilisation of these infirmaries for clinical studies, as to their proposed affiliation to the general hospitals, and as to the merits and demerits of the present system, to another letter, should you be willing to accord me space at a future opportunity.

I am Sirs, your obedient servant,

CHARLES GROSS, M.D. Lond., F.R.C.S. Eng.

St. Saviour's Union Infirmary, Walworth, Feb. 15th, 1887.

*** We have received several other letters on the above subject, for which, however, we cannot find room this week.—ED. L.

MEDICAL CORONERSHIPS.

To the Editors of THE LANCET.

SIRS,—Will you allow me to make a few remarks in reference to this subject, as suggested by Dr. Macdonald's letter which appeared in your issue of last week. Having been a candidate for the last appointment, until promised the deputyship by Mr. R. Collier should he have proved successful, he having held that post for ten years, and having on that promise withdrawn my name from the contest, and now being a candidate and having issued my address in your columns, my remarks may be pardoned on the subject. I quite agree with Dr. Macdonald that the medical and not the legal profession are the proper persons to act as coroners. Dr. Macdonald may not be aware of one clause which now stands in the new Coroners Act, and which I believe has passed the second reading, to the effect that the appointment of coroner should be *only eligible* to barristers or solicitors. Surely this clause has crept in unchallenged. I have seen no allusion to it at all, and therefore draw attention to it. The legal profession are so inundated with appointments that they can well give up their absolute claim to such a post. I quite agree with Dr. Macdonald, that the coroner should, if possible, combine a medical and legal knowledge. Having graduated both in law and medicine, I felt that I had unusual demands for such an appointment. As to the election, I think that it should rest with the Middlesex magistrates, and not with, as has proved to be the case, members of the Odd Fellows, Foresters, and Druids, because they were members of these respective halls, which were in the eastern division of Middlesex; and also with boatmen, who, mooring their boats on the foreshore of the Thames, claimed a privilege to vote. Such farcical nonsense ought surely to be put a stop to, and some Act of Parliament passed to legislate in these matters.

I am, Sirs, your obedient servant,

Feb. 15th, 1887. L. FORBES WINSLOW, D.C.L. Oxon.

"EPIDEMIC DIARRHŒA."

To the Editors of THE LANCET.

SIRS,—We also have been visited in this neighbourhood (St. James's) with an epidemic of diarrhœa—"winter cholera," as the people call it. The attacks come on with great suddenness, often after the evening meal, and, in most of the cases I see, the symptoms become aggravated at night after the patient goes to bed. Severe pain is, as a rule, a prominent symptom, but I have seen more than one case in which, whilst the intestinal catarrh has been profuse, there has been no pain from first to last. I am disposed to attribute the outbreak to atmospheric influences solely.

I am, Sirs, your obedient servant,

Piccadilly, Feb. 15th, 1887. T. BROWNE O'CONNOR.

To the Editors of THE LANCET.

SIRS,—Within the past fortnight several cases of diarrhœa have occurred in my practice in this neighbourhood (Bayswater, W.). Some of the cases have been of extreme severity. The symptoms in all were: pain of a griping character, referred to the region of the umbilicus; frequent diarrhœa of, at first, bilious matter, subsequently becoming of a watery nature; vomiting, thirst, loss of appetite, and general prostration. In one case the symptoms were much aggravated, having, in addition to those above, cramps in the muscles of the abdomen and lower extremities, pulse small, weak, and frequent, almost complete suppression of urine, sunken eyes, and general depression of strength. The attacks lasted from three to six or seven days, and recovered under appropriate treatment. As other districts were affected in a similar manner, perhaps atmospheric influences and water-supply have had a good deal to do with this (at this season of the year) unexpected visitation.

I am, Sirs, yours faithfully,

Pembridge-gardens, W., Feb. 15th, 1887. JOHN WHEELER, M.D.

*** On the above subject Dr. Shirtliff of Kingston-on-Thames also sends a communication, in which he mentions cases that have occurred in his district exhibiting symptoms similar to those described above, and expresses the opinion that the disease is attributable to cold.—ED. L.

THE UNIVERSITY OF EDINBURGH.

To the Editors of THE LANCET.

SIRS,—I have read in THE LANCET of the 12th inst. Professor Rutherford's letter of the 9th inst. I am exceedingly reluctant to enter upon any correspondence in reference to the attack made upon me by Professor Rutherford, more especially after the remarks made by him to his class on the 28th ult. In the course of these he is reported to have said that the time would come when all the facts of the case would be known, and until that time he asked his students to suspend their judgment. I looked upon this statement as an intimation by Professor Rutherford that an inquiry will be made by the Senatus Academicus, or by the University Court, into the whole matter. I can only say that I shall hail such an inquiry with much satisfaction, more especially after what Professor Rutherford

Digitized by Google

has said and written since his letter of apology was given to me. As regards Professor Rutherford's letter of the 9th inst. to THE LANCET, I think it only necessary for me to send you, as I do, a copy of his letter of apology to me of the 17th ult., which speaks for itself. I shall merely further add that immediately after the incident of the 11th of December last, I put the matter into the hands of my solicitors in order that they might take what proceedings they thought necessary for my complete vindication, and that the conclusion of the correspondence with Professor Rutherford's solicitors was that, after consultation by him with his solicitors and counsel, this letter of apology, written by Professor Rutherford's own hand, was received by me.

I am, Sirs, your obedient servant,

Edinburgh, Feb. 15th, 1887. HERBERT H. ASHDOWN.

THE PRESENCE OF BLOOD IN THE PERITONEUM.

To the Editors of THE LANCET.

SIRS,—I am amazed that Dr. Hunter should be so ignorant of the facts of the surgery and pathology of the human peritoneum—he a graduate of the University in the city where Keith lives. He seems to have squirted blood of various kinds and from various sources, foreign and domestic, into the peritoneal cavities of dogs and guinea-pigs without ill results. We, on the contrary, cannot even allow a small quantity of a woman's own blood to remain in her abdomen without fear of trouble; so, following Keith, we clear it out by sponging, washing, and the drainage-tube, with every possible care we can exercise. Then we get good results; and Dr. Hunter ventures to say I have not adduced facts in support of these views. I have been doing as much as I can in this direction for the last twelve years. It is in the human subject, and in that only, that we must look for guiding facts for human surgery. We have been led astray too far and too long by experiments on dogs and guinea-pigs. I am, Sirs, yours &c.,

Birmingham, Feb. 12th, 1887. LAWSON TAIT.

"DR. BRUNTON AND HOMŒOPATHY."

To the Editors of THE LANCET.

SIRS,—In the preface to the third edition of my Pharmacology I have discussed various criticisms of earlier editions, and have also expressed my opinions regarding homœopathy. As the book will be out in a few days, I think it unnecessary to occupy your columns with extracts from the preface.

I am, Sirs, your obedient servant,

Welbeck-street, W., Feb. 14th, 1887. T. LAUDER BRUNTON.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

THE NEWCASTLE DISPENSARY.

THE annual meeting of this old institution has been held, and it has presented its 109th annual report, which shows that the number of letter patients showed a decrease of 826 as compared with the previous year. There was, however, an increase of 2722 in the number of casual patients, and this was the largest number of patients of this class admitted in any one year. The medical report showed that 6201 patients had been admitted by letter, while the total number treated had been 22,936. The medical officer (Dr. Beatley) suggested a closer inquiry into the circumstances of patients by donors of letters of recommendation. The increase of casual patients was in a great measure due to the adoption of a charge in these cases at the Newcastle Infirmary, which had caused an unusual influx at the Dispensary. This gave rise to some remarks from the chairman, Mr. R. H. Holmes, who suggested that it would perhaps become necessary to appoint an officer to make inquiries into these cases. The financial statement was satisfactory. A vote of thanks was given to the medical staff, and the chairman especially referred to the loss the institution was about to sustain in the services of Dr. Beatley, who is retiring to commence practice in this city.

THE CHEST HOSPITAL.

The annual meeting of the Chest Hospital has also been held here. The report showed that 596 patients in all had been treated during the year. An increase over the previous year. This institution is doing as much good as possible within its limited means, but if it is to move with the times and keep pace with the other charities of the city it must throw itself on the public, and at once abolish the "letter" system with which it has been hampered since its birth.

GATESHEAD DISPENSARY.

At the annual meeting of the Gateshead Dispensary just held the medical report showed that the number of patients treated during the year by letter had been 2733; of this number 995 were treated at the hospital and 1738 at their own homes. The total number of patients treated during the year was 13,265, against 12,974 in 1885. The town, it was mentioned, had been wonderfully free from infectious diseases during the past year. The financial statement was satisfactory; there had been an excess of income over expenditure of £166. The chairman, the Rev. Moore Ede, said he believed the time was come when the provident system should be tried side by side with the charitable elements in dispensary management. This brought up Dr. Green, a practitioner in the town, who pointed out that at least one-half of the medical men in Gateshead took patients already on the provident system, a system under which, in the form of a club they paid 3*d.* per week. He (Dr. Green) protested against what was called "the provident system" becoming introduced in connexion with charities, which he contended had their endowments for charity alone. At the suggestion of Dr. Newcombe a committee was appointed in connexion with the dispensary to consider the question of having nurses on its staff in order to attend on patients requiring their aid.

THE MATCH POISONING CRAZE.

Dr. Philipson, in submitting the last annual report of the infirmary, referred to "a remarkable feature in the social history of Newcastle"—namely, the so-called "match-poisoning craze" which has characterised the past year, nine cases of poisoning by phosphorus from a solution of match heads having been admitted into the infirmary, all of which recovered, but after suffering intensely. I may state, in connexion with this "craze," that many cases ended fatally in this city, and in its vicinity the mania had a very rapid "run," so to speak, cases for some time being reported weekly. Happily it now seems to have died out.

Newcastle-on-Tyne, Feb. 14th.

EDINBURGH.

(*From our own Correspondent.*)

THE NEW UNIVERSITY BUILDINGS.

LAST Monday the Chancellor of the Exchequer had an interview with a deputation from the University, consisting of the Principal, the Chairman of the Buildings Committee, and several noblemen and gentlemen, in reference to a proposed grant of £12,000 from Government for the completion of the new medical buildings. Owing to the munificence of a private donor, the University has already at its disposal a sum of money considered adequate to complete the graduation hall and the tower, but as yet no provision has been made for the purchase of the site on which these parts of the original plan of the building are to be erected. In addressing Mr. Goschen, Sir W. Muir and Sir W. Turner laid stress upon the fact that but for lack of means to purchase the site the buildings themselves would already be in course of erection, and urged the desirableness of a Government grant to aid in the completion of works of such national importance. It is feared that the reply of the right honourable gentleman does not indicate any immediate intention on the part of the Treasury to accede to this request, for, while expressing his regard for the interests of the University, Mr. Goschen hinted that there were difficulties of a serious nature in the way of making the grant, chiefly in regard to other claims likely to be strongly represented should the present action give a precedent for such demands. At the same time, he promised that the subject should receive his best consideration; and with this ray of consolation the deputation withdrew. There seems to be a possibility that a much smaller grant than that asked for may be given, on the condition that the remainder of the sum required shall be forthcoming from other sources.

Digitized by Google

In any case, the University authorities deserve high commendation for their energetic efforts. The building, which is a remarkably beautiful piece of architecture, still lacks the balance which a whole additional wing would give it, and in the internal economy of the University the absence of any hall for academic ceremonials is constantly felt to be a pressing want. Now that interest is so thoroughly awakened in the matter, one may fairly hope that at an early date this want will be satisfied.

SCARLET FEVER IN EDINBURGH.

For some weeks scarlet fever has been present in Edinburgh in an epidemic form. All parts of the city and all classes of the community seem equally affected, and the City Fever Hospital is crowded with patients of all ages and conditions, for since it has ceased to be a purely charitable institution, but has been supported by borough rates, it has been much more largely made use of by patients of the upper classes, greatly to the benefit of the public health. At present there are 202 patients in hospital, of whom 150 are suffering from scarlet fever. There is considerable discussion as to the cause of the outbreak. The city medical authorities have not as yet published any special recommendations on the avoidance of infection beyond the directions as to procedure in cases of infectious disease, of which a most useful code has been in the hands of the public for some years. They are, however, very alert in the visitation and isolation of suspected cases, having a most complete system for carrying this out. Failing any special order on the subject from the authorities, Dr. Foulis has written to the local papers recommending that all milk received for domestic consumption should be boiled for five minutes before it is used, and that the vessels containing it should be scalded thoroughly, with the view of destroying the specific virus of the disease. He points out that such a process in no way detracts from the character of the milk as an article of diet, while it is calculated to destroy the germs of most infective diseases. At the meeting of the Town Council, held on Tuesday, Bailie Russell, M.D., convener of the Public Health Committee, announced that the Fever Hospital was filled with patients beyond the limits of its intended accommodation, and that the Council must at once undertake to furnish additional wards. This was agreed to, and relegated to the Public Health Committee, with full powers to act. A large addition has also been rendered necessary in the nursing staff. Up to the present there has been a daily increase in the extent of the epidemic.

Edinburgh, Feb. 15th.

DUBLIN.

(From our own Correspondent.)

ALLEGED ILL-TREATMENT OF A PATIENT IN MERCER'S HOSPITAL.

IN the Green-street Court-house last week, before Mr. Justice Murphy, Dr. B. Kennedy, resident surgeon of Mercer's Hospital, was indicted for having assaulted a patient named Farrell, in August last. Dr. Kennedy had been indicted for manslaughter, but the bill had been thrown out by the grand jury; after some evidence had been given, the jury were of opinion that the case should not go on, to which his lordship agreed. He said that Dr. Kennedy would not have been warranted in leaving a delirious man among the other patients, for if anything had happened in consequence he would have been censured. He could not say from the evidence that he had used unnecessary violence. The case had been got up against Dr. Kennedy by witnesses obtained here and there, and suggestions made by a man who was expelled from the hospital, but who did not now appear. However, it was best for the accused that an open investigation in that court should be held. The jury acquitted Dr. Kennedy, and appended the following rider to their verdict :—"We consider that, according to the evidence, Dr. Kennedy should not have been subjected to the hardship of a prosecution." All must sympathise with Dr. Kennedy in the anxiety, annoyance, and expense to which he has been so unjustly subjected.

THOMPSON MEMORIAL HOME, LISBURN.

This institution, founded in 1885 in memory of a distinguished surgeon, was established for the admission of patients suffering from incurable diseases. The Home was founded by the widow, daughter, and son-in-law of the late Dr. Thompson. I may state that the site, grounds, furniture, and fittings cost £23,767. The second annual meeting was held last week, when it was shown that at the close of 1886 there were thirty-six patients in the Home, while the income exceeded the expenditure by about £300. To the sum of £60,000, set apart by the promoters of the charity, Mrs. Bruce has added £10,000 in memory of her mother (Mrs. Thompson), and also a sum of £5000 in memory of her brothers. It is contemplated to admit deserving cases until the inmates number fifty-five. The memorial is a magnificent one, considered as the outcome of generosity on the part of a single family.

CITY OF DUBLIN HOSPITAL.

This morning I had an opportunity of seeing some very interesting cases at this hospital. A tumour of the occipital region with marked head symptoms, which probably will require Mr. Wheeler to trephine; and a patient of the same surgeon with aneurysm, for which he may be obliged to ligature the subclavian or arteria innominata. An obscure tumour (probably malignant disease of the pancreas), under Mr. Henry Fitzgibbon; also under the latter gentleman's care a case of a child who some time since fractured his thigh, and though union has taken place, there exists a piece of bone the size of a walnut, which freely moves about, and yet there is no shortening. There is also under Mr. H. Gray Croly a case of lumbar colotomy, with interesting details, this being his ninth successful case. The same morning Mr. Fitzgibbon operated for external piles, with Smith's clamp, knife, and thermo-cautery.

NATIONAL EYE AND EAR INFIRMARY.

The performance of the "Sleeping Beauty," held last month in aid of the funds of this hospital, has realised a sum of £62 13*s.* 11*d.*

KILKENNY TOWN COUNCIL AND ANALYST'S FEES.

At the quarterly meeting of the Town Council last week a notice of motion that the services of Sir Charles Cameron be dispensed with was under consideration. The majority of the Council appeared not to value the services of the eminent medical officer of health and city analyst for Dublin; they considered that the local medical practitioners were sufficiently skilled to undertake analytical duties, probably forgetting that a special course of study is absolutely necessary, and that the salary attached to the post (£5 per annum) would not defray the interest on the cost of the necessary instruments. The resolution, however, was adopted by eleven votes against three.

Dr. C. Nixon has been appointed a member of the Senate of the Royal University of Ireland, vice Dr. Lyons, deceased.

Dublin, Feb. 15th.

ROME.

(From our own Correspondent.)

OUR Lady of Snow paid a memorable visit to Rome on August 5th, A.D. 352, and the miracle—a snow-heap on the Esquiline, near the market of Livia—caused the reigning Pope Liberius to erect in her honour the Basilica of Santa Maria Maggiore, which, says Freeman, "remains to show what a Christian Church looked like in the days of the first triumph of the faith." Hardly less of a miracle in modern Roman eyes—though certain to have no such august commemoration—has been the two days' snowfall which has just given the Eternal City the aspect of a Swiss town in midwinter and converted the surrounding hills into a bijou Bernese Oberland. Nonagenarian survivals from last century can recall no similar portent in the Urbs Septicollis, while the latest accessions to the English-speaking garrison flock to every elevated point within or without the walls to enjoy a panorama as magnificent as it is unique. "Ave Maria" tolls from a hundred belfries, but groups of spectators yet linger on the Loggia of the Pincio, or the esplanade of San Pietro in Montorio, to revel in the solemn sunset, or to draw from its "mighty missal-page" a lesson or homily not unbefitting the devotional hour.

Another phenomenon much more familiar, though scarcely less picturesque, is apt to follow from heavy snowfall on the Umbro-Sabellian uplands. The Tiber, swollen by the

Digitized by Google

melted snow, has only to be impeded at its outlet by a steady west wind, and its regurgitant waters flood the city and reduce it for a time to something like Venice. For such an invasion—the only one that King and Consul, Emperor and Pope, have alike failed to repel—experience has provided palliatives, if not remedies; and the pontoon service, patrolling the nocturnal streets with flambeaux, and, in the Jews' quarter, filling with bread the baskets lowered from second and third storeys for the refection of the isolated inmates, will add another to the picturesque situations which somehow never fail the visitor in Rome. Meanwhile, the health of the city is admirable; hardly a case of fever has been known for weeks; and if the magnificent weather, with its skies of azure and its lovely spring sunshine, have tempted enthusiastic archæologists or artists to outstay their strength in damp ruins or gusty basilicas, the result has been oftener seen in catarrhs or mild bronchitic attacks than in any more serious ailment of the respiratory or circulatory systems.

Not Rome, but Florence, has this season been the centre of sanitary interest; and now that the City of Flowers has been able to clear herself of the imputations directed at her by non-professional censors, it is again the turn, not of Rome, but of Umbria and Upper Italy, to attract the attention of the hygienist. A trichina scare has just been averted from Camerino and that populous agricultural neighbourhood by the prompt intervention of the municipality. A man suffering from aggravated trichinosis died in spite of skilled medical treatment, and immediately the Town Council forwarded an arm of the deceased to Professor Perroncito, the distinguished helminthologist of Turin, for examination. The Professor's report declared that microscopic inspection revealed extensive inter-fibrillary trichinosis in the limb; and, acting on this indication, the health officers of Camerino and district microscopically examined the wares of the pork-butchers' shops, and, as a result, redoubled their vigilance at the slaughter-houses for the supply of such meat. It was proved that, in the fatal case just mentioned, the pork consumed had been of foreign importation; and so, in this direction likewise, a strict surveillance is reimposed on all swine-flesh of non-Italian origin.

A yet severer scourge, for the most part confined to Northern Italy, has also been the subject of preventive legislation. The Chamber of Deputies has now before it the Bill of Signors Grimaldi and Magliani (the Ministers of Commerce and Finance) for excluding from the alimentation of the peasant unsound wheat, or rather maize, the nearest equivalent for the Italian "gran turco." Such food, the chief cause of pellagra, will be put out of reach of the poorer population of the agricultural districts by the establishment of "essiccatoi," or desiccating apparatus, by which the maize is presented for food only when by evaporation it has been deprived of all pellagra-causing elements. Where communes are unable to provide such "essiccatoi" for themselves, they are to be aided towards that end by State subsidies, the aggregate of which shall not exceed 50,000 lire (£2000) annually. This seems a small sum for such an object when we consider that the pellagra-stricken communes in Italy amount to 2453, according to the last returns in 1881. But Signors Grimaldi and Magliani set forth in their Bill that in some of these communes desiccation of the maize is effected without special apparatus, and that in others private enterprise or benevolence provides such apparatus gratuitously. There remain of the communes that require State help for the supply of "essiccatoi" not more than the subvention will amply cover, an "essiccatoio" costing on an average some 2000 lire (£80).

Italy, more than any other European country, is lavish of honours to her great physicians and surgeons. Francesco Puccinotti, the classic historian of medicine, the translator of Aretæus, the acutest intellect ever applied in Italy to medical jurisprudence, author of memorable treatises on epidemics peculiar to the nineteenth century, and in all respects exemplary as a citizen, is about to receive in the Santa Croce of Florence (the Walhalla of distinguished Italians) the tribute of a monument in bronze. Urbino, his native town, heads the subscription-list with 1000 lire (£40), and the Universities of Pisa and Macerata, with the Institute of Higher Studies in Florence, are combining to augment it by their own contributions and those of other seats of learning.

An important addition has just been made to sanitary literature by Dr. Giuseppe Pinto. "I Rioni di Roma, considerati dal Lato Igienico" (The Regions of Rome considered in their Hygienic Aspect). Dr. Pinto's work will be found to warrant the high expectations formed from his previous contributions to the same interesting discussion.

Rome, Feb. 12th.

THE SERVICES.

WAR OFFICE. — Army Medical Staff: Surgeon-Major Gough Ashton, M.B., is granted retired pay; Surgeon-Major Sandford Moore, M.B., is granted retired pay, with the honorary rank of Brigade Surgeon.

ADMIRALTY. — The following appointments have been made:—Surgeon P. E. Maitland, to the *Acorn;* Surgeon S. T. O'Grady, to the *Lion;* Surgeon J. J. Walsh, M.B., to the *Vernon*, additional; and Patrick J. Sheridan to be Surgeon and Agent at Kilmore.

YEOMANRY CAVALRY. — Royal East Kent: Honorary Brigade Surgeon Owen William George, M.D. (late 1st Life Guards) to be Surgeon.

ARTILLERY VOLUNTEERS.—2nd Volunteer (Devonshire) Brigade, Western Division, Royal Artillery: Frederick Adams Dawson, M.D., to be Acting Surgeon.

MEDICAL NOTES IN PARLIAMENT.

Army Medical Officers.

IN the House of Commons, on the 15th inst., Sir G. Hunter asked the Secretary for War whether, in the recent Army Warrant, any alteration had been made in the relative rank, position, or titles of medical officers to those heretofore held by them. Mr. E. Stanhope replied that relative rank has been abolished for all departments; but medical officers retain all the privileges heretofore attaching to it, and that in other respects their status is unchanged.

Police and Sanitary Regulations.

On the 16th inst., on the motion of Mr. Stuart-Wortley, it was resolved that the Committee of Selection should appoint a committee, not exceeding nine members, to whom should be referred all private Bills promoted by municipal and other local authorities, by which it was proposed to create powers relating to police and sanitary regulations which deviated from, or were in extension of, or were repugnant to, the general law.

Open Spaces.

Leave was given to Sir J. Lubbock to bring in a Bill for extending certain provisions of the Metropolitan Open Spaces Act, 1881, with amendments, to urban sanitary districts throughout England and Wales. The Bill was read a first time.

Obituary.

PROFESSOR BÉCLARD.

M. JULES BÉCLARD, who died somewhat suddenly last Wednesday, was the son of the celebrated anatomist Pierre Augustin Béclard. He was born in 1818. After passing through his medical curriculum in Paris, he became house-physician to the Asylum of Charenton, where he remained for three years. In 1842 he took the degree of Doctor of Medicine. His first scientific publication was "Les Eléments d'Anatomie Générale," which had been left in manuscript by his father. Pursuing the same line of study, he published in 1864 the results of his researches on the Cartilaginous System. These were followed by memoirs on "Muscular Contraction in its relation to Animal Temperature," "On the Influence of the Temperature upon the Comparative Development of Organic Systems," "On the Functions of the Spleen," "On the Influence of Light," and "On the Development of Animals." Besides these, M. Béclard furnished numerous contributions to the "Dictionnaire Encyclopédique des Sciences Médicales," and at one time was a frequent writer in the *Gazette Hebdomadaire.* But his principal work was his "Traité de Physiologie Humaine," which has reached its seventh edition, having now been for more than thirty years the standard

Digitized by Google

text-book for French students. At the University, Béclard obtained his first success in the competition for the Assistant Professorship (*Agrégation*) of Anatomy and Physiology, the unsuccessful candidate being the illustrious Claude Bernard. Two years later, in 1846, being at the time only twenty-eight years of age, he competed for the chair of Anatomy unsuccessfully, and in 1852 he again failed to secure the lectureship on Hygiene. The *concours*, or public competition, being afterwards abolished, Béclard was obliged to wait until the death of Longet, whom he succeeded as Professor of Physiology in 1871. Elected to the Academy of Medicine in 1862, he was at once named annual secretary, and the remarkable panegyrics which he pronounced in this capacity designated him in advance for the functions of perpetual secretary, to which post he succeeded on the death of M. Dubois. In 1881 he became Dean of the Faculty of Medicine, after the death of Professor Vulpian, a dignity which he held at the time of his death.

Béclard had studiously abstained from practice, and devoted all his energies to his duties as a professor and to his functions as perpetual secretary of the Academy of Medicine. When he was nominated Dean of the Faculty his talents as an administrator became evident, and upon the expiration of his first term of office its renewal was claimed by the unanimous vote of all the members of the Faculty, both professors and *agrégés*. His extreme affability, his impartiality, and his well-known kindness made him a favourite with all classes, and no Dean was ever more regretted, both by his colleagues in the professoriate and the students placed under their tuition. In fact, it may be said that Béclard had none but friends—a happy fate for a man of perfect integrity, and who never failed to defend what he thought to be the right.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentleman passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise on the 3rd inst.:—

Chapman, Robert Hugh, M.R.C.S., Halford-road, Richmond.

Passed on the 10th inst.:—

Skelding, Henry, M.R.C.S., M.B., B.C. Camb., Euston-square.
Bartholomew, Alfred Adam, Crowle, Doncaster.

A BALL was held at the Bristol Lunatic Asylum on the 9th inst.

THE annual ball in aid of the funds of the Liverpool Stanley Hospital was held on the 9th inst.

DR. W. SEDGWICK SAUNDERS, medical officer of health and public analyst for the City of London, last week celebrated his silver wedding.

THE annual meeting in connexion with the South Devon and East Cornwall Hospital was held on the 8th inst., Sir Massey Lopes presiding.

THE Right Hon. G. Sclater-Booth, M.P., has accepted the Presidentship of the Congress of the Sanitary Institute of Great Britain, to be held at Bolton in September next.

UNDER the will of the late Mrs. Elizabeth Hughes, the City of Dublin Hospital has received a sum of £997 2*s.* 5*d.* Mr. Alexander Finlay has given £50 to the Belfast Royal Hospital.

The annual Hospital Sunday collections in aid of the medical charities of Manchester and Salford were made on the 14th inst. The Hospital Saturday collection is to be held on the 19th inst.

ARRANGEMENTS have been made for holding this year a Hygienic Exhibition at Warsaw. The exhibition will be divided into five groups, comprising respectively the hygiene of food, of dress, of dwellings, of schools, workshops, and hospitals, and, finally, statistics and meteorology. The opening is fixed for May 15th, the closing for July 1st.

AT the annual general meeting of the governors of and subscribers to the Nottingham Coppice Hospital on the 10th inst., satisfactory medical and financial reports were presented and adopted.

THE annual meeting in connexion with the Essex and Colchester Hospital was held on the 10th inst.

BRADFORD INFIRMARY AND DISPENSARY.—The sixty-second annual meeting of the governors of this institution was held on the 8th inst. The total number of in-patients during the past year was 1511, and of out-patients 5330, as compared with 1385 and 5137 respectively in 1885. The income amounted to £8110, and the expenditure to about £7842.

ROYAL GENERAL DISPENSARY.—The annual meeting of the governors of this institution was held on the 14th inst., when the report showed that during the past year 11,050 cases had come under the notice of the medical officers, 3684 being new cases, and 2178 visits had been made to 546 patients at their own homes. The statement of receipts and expenditure was satisfactory, there being a balance at the bankers of £62.

THE thirty-fourth annual meeting of the Manchester and Salford Sanitary Association was held on the 4th inst.

HOSPITALS ASSOCIATION.—The third general meeting of the members of this Association was held on the 16th inst., when a paper written by Miss Manson, Matron of St. Bartholomew's Hospital, entitled "Is it Desirable for Metropolitan Hospitals to possess Nursing Institutions, and to supply Nurses for Private Cases outside the Hospital Walls?" was read by Dr. Bedford Fenwick.

BROMPTON CANCER HOSPITAL.—The annual meet- of the governors of this charity was held on the 16th inst. From the report of the committee, it appears that during the past year 1028 new patients were received, 652 being in-patients, and 976 out-patients. The total number of visits of new and old out-patients was 6276, against 5360 in 1885.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Professor Charles Barrett Lockwood, F.R.C.S., will deliver a course of three lectures on "The Development and Transition of the Testicle, Normal and Abnormal," on Wednesday, Friday, and Monday, Feb. 23rd, 25th, and 28th, at 4 P.M. precisely each day. Students desirous of attending these lectures are admitted on the introduction by a Fellow or Member of the College.

THE JUBILEE.—At a meeting at Chipping Norton on the 8th inst., it was decided to erect a cottage hospital to commemorate the Queen's Jubilee. A site of land has been presented and several subscriptions are already promised. A suggestion has been made that the Children's Hospital in Great Ormond-street be completed by means of a subscription raised among the children of England in celebration of the Jubilee.

GUY'S HOSPITAL.—Mr. J. S. Morgan has promised £10,000 in aid of the funds of this hospital, on condition that the amount required to put the institution into a state of thorough efficiency—viz., £100,000—be secured on or before the 1st day of May next. A grand afternoon concert in aid of the Special Fund will be given at Willis's Rooms on the 22nd inst., when Mdlle. Antoinette Trebelli, Madame Patey, Mr. Edward Lloyd, Mr. Santley, and other distinguished artists will appear.

THE TRAINED NURSES' ANNUITY FUND.—The Committee of the Trained Nurses' Annuity Fund desire to call the attention of lady superintendents and matrons of hospitals, infirmaries, &c., to the existence of this fund, which was founded in 1874, and has been steadily increasing ever since. At this moment twelve annuities of £15 per annum have been permanently founded, and above £4000 is invested in the hands of trustees, the interest of which pays the annuitants, so that there is no danger of an annuity failing through lack of funds; but the number of applicants is daily increasing. It is calculated that there are now about 10,000 nurses in the United Kingdom. If each would give 1*d.* a month or 1*s.* a year towards the fund, its powers of usefulness would rapidly increase. Lady superintendents and matrons would therefore do well to bring this matter before the nurses on their staff, and to plead on behalf of their sisters whose health has broken down under the fatigue and anxiety of their arduous profession. Communications may be addressed to R. Gofton Salmund, Esq., hon. secretary, 73, Cheapside, London, E.C.; or to Lady Bloomfield, Shrivenham, Berks.

Digitized by Google

DEATHS FROM CHLOROFORM.—On the 10th inst. an inquest was held at Sheffield on the body of a woman who had died from the effects of chloroform, which had been administered for the performance of an operation. A verdict of death from syncope was returned. On the 14th inst. an inquest was held at the Ipswich and East Suffolk Hospital on the body of a man who had died at that institution while under the influence of chloroform. The jury returned a verdict in accordance with the evidence, and exonerated the medical man from all blame in the matter.

CITY OF LONDON LYING-IN HOSPITAL.—The 136th annual meeting of the governors of this well-known and deserving charity was held on the 9th inst., when the Committee of Management submitted a report stating that the year 1886 had in many respects been a satisfactory one. There had been an increase in the number of both in- and out-patients, an increase which had been accompanied by a reduced mortality. The number of in-patients delivered during the year had been 283; 287 children had been born—viz., 131 boys and 156 girls; 15 children were still-born; 3 women and 5 children had died. In the out-patient department 1249 women had been delivered, as against 1118 in 1885. The income for the year from all sources, together with the balance left over at the end of 1885, was £3166, while the expenditure amounted to £2925.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BROOK, W. F., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

BROWN, C., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Throat Department of St Thomas's Hospital.

BULSTRODE, H. T., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

CALVERT, J. T., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

CLARKE, FREDK. H., M.B., C.M.Ed., has been appointed House-Surgeon to the Great Yarmouth Hospital.

DAVIES, E. T., M.D., C.M.Ed., has been reappointed Assistant Surgeon to the Hospital for Women, Shaw-street, Liverpool.

EVANS, C. S., M.B.Cantab., M.R.C.S., L.S.A., has been reappointed Resident House-Physician to St. Thomas's Hospital.

FITZGERALD, G. C., B.A., M.B., B.C.Camb., M.R.C.S., has been appointed Junior Assistant Medical Officer to Cane-hill Asylum, Surrey, vice H. Gardiner Hill, promoted.

HAWKINS, H. P., M.R.C.S., L.S.A., has been appointed Assistant House-Physician to St. Thomas's Hospital.

HINSHELWOOD, JAMES, M.A., M.B., C.M., has been appointed House-Surgeon to the North Riding Infirmary, Middlesbrough-on-Tees, vice Fraser, resigned.

HUTTON, J. S., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed House-Surgeon to St. Thomas's Hospital.

MACEVOY, H. J., L.R.C.P., M.R.C.S., has been appointed Resident Accoucheur to St. Thomas's Hospital.

MONTAGUE, A. J. H., M.B.Dur., L.R.C.P., M.R.C.S., L.S.A., has been reappointed Non-resident House-Physician to St. Thomas's Hospital.

O'BRIEN, P. M., M.R.C.S., has been appointed Resident Medical Officer to the North London Hospital for Consumption, Hampstead.

PESKETT, ALFRED FREEMAN, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the Leyton Urban District, and Surgeon to the Master Bakers' Almshouses, vice A. Peskett, M.D., deceased.

PHILLIPS, H. HEYGATE, M.D., L.R.C.S.I., has been appointed an Honorary Consulting Surgeon to the Reading Dispensary.

SANSOM, H. A., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

SKELDING, H., M.B., B.A.Camb., M.R.C.S., L.S.A., St. Bartholomew's Hospital, has been elected Resident Surgeon to the Bedford General Infirmary, vice Pynsent C. Smith, whose term of office has expired.

SOLLY, E., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

STABB, H. C., L.R.C.P., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

STACY, J. H., L.R.C.P., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator to the First District of the Henstead Union, Norfolk, vice T. W. Richardson, M.R.C.S., L.S.A., resigned; also Medical Officer to the Sixth District of the Norwich Union, vice C. W. Doyle, M.B., resigned.

STAVELEY, W. H. C., L.R.C.P., M.R.C.S., has been appointed House-Surgeon to St. Thomas's Hospital.

SYMES, E. WEST, M.D.Edin., M.R.C.S., has been appointed Medical Officer to the Halifax Post Office, vice Solomon Smith, M.R.C.S., &c., resigned.

SYMES, G. DICKINSON, M.R.C.S., late Clinical Resident, Bethlem Royal Hospital, has been appointed Assistant Medical Officer to the Lancashire County Asylum, Rainhill.

TONKING, J. R., L.R.C.P., M.R.C.S., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

WALDO, F. J., M.A., M.D Cantab., M.R.C.S., has been appointed Assistant Physician to the Chelsea Hospital for Women.

WHEATLY, A. W., M.B., S. Sc.C. Dur., M.R.C.S., has been appointed Surgical Registrar and Anæsthetist to the National Orthopædic Hospital.

WHEATON, S. W., L.R.C.P., M.R.C.S., has been reappointed Resident House-Physician to St. Thomas's Hospital.

WILLOUGHBY, EDWARD F., M.B.Lond., M.R.C.S., has been appointed Chief Medical Officer to the Sanitary Assurance Association, vice Stevenson, resigned.

WINFIELD-ROLL, G., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Second Ophthalmic Clinical Assistant to St. Thomas's Hospital.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY.—Assistant House-Surgeon (qualified or unqualified). Board and washing, but no salary.

ECCLES AND PATRICROFT HOSPITAL, near Manchester.—House-Surgeon. Salary £60 per annum, with board and rooms.

ROYAL PIMLICO DISPENSARY.—Medical Officer.

SALFORD AND PENDLETON ROYAL HOSPITAL.—District Surgeon. Salary £80 per annum, with board and lodging.

Births, Marriages, and Deaths.

BIRTHS.

BUSHE.—On the 10th inst., at Beaufort Lodge, Hounslow, the wife of Surgeon-Major Cecil Bushe, M.B., Medical Staff, of a son.

CHAPMAN.—On the 11th inst., at Denham House, Goldhawk-road, W., the wife of C. W. Chapman, L.R.C.P.Lond., M.R.C.S., of a son.

GAIRDNER.—On the 10th inst., at Gibson-square, N., the wife of John Gairdner, M.R.C.S., L.S.A., of a son.

HENTSCH.—On the 11th inst., at Portland-place, Camberwell, S.E., the wife of John Page Hentsch, M.R.C.S., of a daughter.

OGILVY.—On the 9th inst., at Bournemouth, the wife of Surgeon-General Ogilvy, of a son.

TRIPP.—On the 5th ult., at Herat, Institution-hill, Singapore, the wife of C. Ll. H. Tripp, M.R.C.S., L.R.C.P.Lond., L.S.A., of a daughter.

MARRIAGES.

BERRY—BALDWIN.—On the 8th inst., at St. Saviour's, Paddington, F. C. Berry, M.D., to Charlotte Meers, daughter of the late G. T. Baldwin, Esq., of Fakenham, Norfolk.

BLANCARD—TAYLOR.—On the 9th inst., at St. George's Church, Ramsgate, by the Rev. C. E. Shirley Woolmer, Vicar of Ramsgate, Surgeon J. T. Blancard, Indian Medical Staff, to Edith Emma Mary, younger daughter of Charles Taylor, Esq., late of Ealing College.

BRADBURN—CHILCOT.—On the 14th inst., at Christ Church, Ealing, W., by the Rev. J. S. Hilliard, M.A., James Denham Bradburn, F.R.C.S.Edin., eldest son of James Bradburn, Esq, of Monks' Hall, Eccles, Lancashire, to Emily Victoria, widow of the late Jas. Chilcot, M.R.C.S., of Mere, Wilts.

DYSON—WALL.—On the 10th inst., at Stoke Prior Church, by the Rev. Harcourt Aldham, B.A., Thomas Edward Dyson, M.B., I.M.S., to Annie, eldest daughter of the late Wm. Wall, Esq., of Stoke Prior, Worcestershire.

GOSTLING—PARKINSON.—On the 10th inst., at St. Mark's, West Hackney, by the Rev. J. G. Pilkington, M.A., Vicar, William Ayton Gostling, M.D., of Worthing, Sussex, to Frances Marion, only daughter of Mr. G. H. Parkinson, of the Royal Courts of Justice, London.

HOLT—BUSTEED.—On the 9th inst., at Isleworth, Percy Holt, Army Medical Staff, to Sarah, only daughter of T. M. Busteed, Esq., Barrister-at-Law, Indian Judge, retired.

STEDMAN—BUCKLEY.—On the 10th inst., at St. James's, Norlands, John Buck Stedman, F.R.C.S., to Emma Buckley, widow of the late John Buckley, Esq., of Manchester.

DEATHS.

AMBLER.—On the 6th inst., at Colville-square, Bayswater, Vincent Ambler, M.D.

BRADDON.—On the 5th inst., suddenly, at his residence, Ham House, Upton-on-Severn, Charles Braddon, M.R.C.S., aged 71.

BUTT.—On Dec. 20th, 1886, at Blenheim, New Zealand, the Venerable Archdeacon Henry Francis Butt, M.R.C.S., in the 71st year of his age.

GIBSON.—On the 16th inst., at Kirkland, Campbeltown, Argyllshire, Gregory Gibson, Medical Student, aged 23.

PRENTIS.—On the 14th ult., at Calcutta (on his way to England), Surgeon-Major Chas. Prentis, Bengal Medical Service, M.R.C.S., F.L.S., &c., late of Gorakhpur, in his 52nd year.

RIDER.—On the 10th inst., John Rider, of Wellington, Shropshire, M.R.C.S., L.S.A., aged 64.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, February 21.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. E. Milner: On the Different Modes of Administering Mercury in Syphilis, and the Indications for their Application.
SOCIETY OF ARTS.—8 P.M. Mr. W. Y. Dent: Building Materials (Cantor Lecture).

Tuesday, February 22.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Respiration.
SOCIETY OF ARTS.—8 P.M. Mr. J. Starkie Gardner: Wrought Ironwork.
ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Prof. Ferrier: The Functional Topography of the Brain.—Mr. H. D. Rolleston: Description of the Cerebral Hemispheres of an Adult Australian Male.—Mr. Sören Hansen: On a Fossil Human Skull from Lagoa Santa, Brazil.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Henry Morris: A case in which the Urinary Bladder was twice Ruptured, the first time by an Injury, the second time—seven years after the first—by the giving way of the Cicatrix.—Mr. W. H. Bennett: A case of Extra-peritoneal Rupture of the Urinary Bladder, the Direct Result of Aspiration above the Pubes, with Remarks on Some Objections to the Use of the Aspirator as a Means of Evacuating the Bladder, and Suggestions for the Treatment of certain cases of Retention of Urine.

Wednesday, February 23.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
SOCIETY OF ARTS.—8 P.M. Mr. John W. Urquhart: Recent Advances in Sewing Machinery.
HUNTERIAN SOCIETY.—8 P.M. Dr. Scarth: A Review of Forty Cases of Diphtheria, illustrating its Manner of Spreading, and its Relations to other Fevers, to Diathesis, and to Neurotic and Paralytic Conditions.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown. Adjourned Discussion on Dr. Fitzgerald's paper on the Use and Abuse of Pessaries. Council at 8 P.M.
NEUROLOGICAL SOCIETY OF LONDON.—8.30 P.M. Exhibition of Clinical Cases.

Thursday, February 24.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Edmund Gosse: The Critics of the Age of Anne.

Friday, February 25.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF ARTS.—8 P.M. Mr. Holt S. Hallett: New Markets and Extension of Railways in India and Burmah.
QUEKETT MICROSCOPICAL CLUB.—8 P.M. Annual General Meeting for Election of Officers. President's Address.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Hughlings Jackson: A case of Paralysis of Left Leg from Subcortical Disease.—Dr. Carrington: A case of Rheumatic Hyperpyrexia treated by the Cold Bath.—Dr. Hadden: A case of Epilepsy following an Injury to the Leg.—Mr. Bowlby: Cases of Profuse Hæmaturia in connexion with Granular Kidney. Living Specimens: Dr. Arthur Davies: Two cases of Myxœdema (male and female).
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Captain W. de W. Abney: Sunlight Colours.

Saturday, February 26.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. The Right Hon. Lord Rayleigh: Sound.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE EFFECTS OF ALCOHOL.

A. G.—It is not possible to state with arithmetical precision the proportion of diseases due to alcohol. It is certainly very large. Medical opinion on the diseases due to alcohol is to be gathered from various quarters, rather than from any one book. The views of many eminent medical men may be found in the evidence taken on the subject by the Committee of the House of Lords in 1878–9. There is a preponderating amount of medical opinion to the effect that all but a very moderate amount of alcohol to the majority of people is injurious.

WILL *Medicus* (Salford) kindly forward his card, as the one sent has been mislaid.

NIGHTMARE.

To the Editors of THE LANCET.

SIRS,—I should be much obliged to any *confrère* who would kindly advise me what to do for nightmare, greatly affecting sleep and proper rest. I have no sensation of fright, but wake up after distressing dreams, with disturbed heart's action, flushed face, &c. The amount of nightly disturbance varies; but the shortest interval between falling asleep, dreaming a long dream, and waking has been as little as five minutes. No particular symptoms referable to any special organ in fault. Proximate cause probably due to liver disturbance. I am fifty years of age, and have some lung trouble of five or six years' standing, now quite chronic, and limited to slight expectoration and occasional slight hæmoptysis. I am, Sirs, yours faithfully,

February 15th, 1887. M.D.

ONE REASON FOR AN URGENT CALL INTO THE COUNTRY.

A FRENCH practitioner received a call one afternoon, about five o'clock, from one of his country patients, a farmer who had been in town at market all day, who requested him to drive over at once to see a member of his family. The case not appearing to be urgent, the doctor replied he would go in the morning. "Oh, that will not do at all," said the farmer. "I ask you to go now because I want a lift home, and to hire a trap will cost more than your visit."

Dr. Reihlen (Stuttgart).—We cannot exchange.

COLORADO.

To the Editors of THE LANCET.

SIRS,—I would feel thankful if some of your numerous correspondents would give me their experience of the climate of Colorado for consumptives, and also their opinion of its relative advantages as compared with other climates. I am, Sirs, yours truly,

Feb. 14th, 1887. A PHYSICIAN.

HEAT HOLIDAYS.

WE extract the following paragraph from the *New York Medical Record* of Feb. 5th:—"In Switzerland and some parts of Germany the law provides that all schools, public or private, must give the scholars a holiday whenever the temperature reaches a certain height. The regulations in Basle are that when the temperature reaches 77° F. in the shade by 10 A.M. the school must be closed until the late afternoon. These heat holidays are very popular among the scholars."

Dr. Thos. Reid.—The R.C.P. Edin. does not pretend that its licence is a qualification in surgery as well as physic, as the London College has always maintained is the case with its licence, and as the public bodies have recognised. This statement virtually answers all our correspondent's other questions.

M.D.—The statements contained in the extract from the "chatty letter" are so completely at variance with the results of our own inquiries that we cannot undertake to publish it without more precise and detailed information.

WE have received from *Messrs. Ellis and Steele*, hon. secretaries of the Association of Members of the Royal College of Surgeons, a communication for which we regret we are unable to find space this week.

"DROWSINESS ACCOMPANYING DYSPEPSIA."

To the Editors of THE LANCET.

SIRS,—Drowsiness accompanying digestive troubles is very common; but I think your correspondent, "L.R.C.P. Lond., M.R.C.S.," will find it most extreme in cases resembling the following:—The patient is anæmic and irritable, troubled with palpitation, and sensation of fulness after meals caused by flatus. Bowels may be constipated or not. Used to a sedentary life. The principal points, however, to be looked to are the teeth and urine; the former are bad, and the latter scarcely acid, or else alkaline, and often phosphatic. Alkalinity or deficient acidity is probably present in the stomach, and germs from the teeth swallowed in the saliva. In the stomach, as a rule, the trouble commences; hence the distension and, from pneumogastric irritation, the palpitation. Pepsine can only act in an acid medium, and so the food undergoes some abnormal decomposition, with the production of gas, instead of normal digestion. It is not difficult to imagine that the products of such changes, taken up and passing through the liver into the general circulation, would produce toxic symptoms. The brain, already badly nourished and anæmic, cannot work with blood deficient in oxygen-carrying corpuscles and loaded with morbid products as well. It therefore "sleeps," disturbed, however, by fitful dreams as more or less irritating matter is supplied to it.

What should be the treatment of such a condition? Simply supply what is deficient. If there be constipation, a mild aperient—say, ext. cascar. sag., gr. iii., o. m. ante cib. Attend to the teeth. For the alkalinity and palpitation the following:—℞. Acidi hydroch. dil., m. xv.; tr. nucis vom., m. x.; tr. columbæ, m. xv.; aquam ad ℥i; ter die post cibos, with or without succus taraxaci, ʒi., or vin. pepsin., ʒi., as required. Limit smoking. Stop all tea, coffee, cocoa, and hot fluids. Let the patient drink cold water for breakfast, light ale, claret, or water at dinner—say, at 2.30—and a light supper at 8 P.M., with the same drink, and no fluid between meals. Nearly finish every meal before drinking. Advise friction with a towel over the abdomen, sufficient out-door exercise, and early bed.

I am, Sirs, yours faithfully,
Feb. 14th, 1887. F. T. S.

"PASSING RICH ON £40 A YEAR."

[THE guardians of a Norfolk union advertise for a district medical officer for ten parishes at a stipend of £40 a year, with extras, he to supply all medicines.—*Local paper.*]

The country parson who, in olden days,
Formed the choice subject of a poet's praise
Spent a calm life of usefulness and cheer,
And thought him "passing rich on £40 a year."

Now Poor-law surgeons, rich in physic's lore,
For arduous work in places half a score,
All drugs supply, the sick poor's ills allay,
And £40 a year's the bounteous pay.

The parson lived in frugal days of old;
His wants were few, hence scant was then his gold.
Not so the doctor of the present day:
His wants are many, small howe'er his pay.

Eastern Daily Press.

A QUERY.

To the Editors of THE LANCET.

SIRS,—I have had twenty years of grilling in India, and am now on my way home, with the intention of spending a year or two there. I fear the cold of the home winter unless I can get some sheltered spot by the sea, wherein to pass the cold season under favourable circumstances. I do not care whether the time be passed in England or Ireland, if I can only be sure of a mild and tolerably equable temperature by the sea. I shall feel much obliged if some of your readers will favour me with advice as to the best place to go to which shall fulfil the foregoing conditions and be tolerably cheap.

I am, Sirs, yours faithfully,
February, 1887. J.

A ROMAN SKELETON FOUND AT PLUMSTEAD.

A SHORT time since a most interesting discovery was made by some workmen in a field at Plumstead of a leaden coffin containing a skeleton. Various persons, more or less learned in antiquarian matters, all coincided in placing the date of the leaden coffin about 1500 years ago, and as being probably of Roman workmanship. The owner of the ground promised to give the remains to a medical man for a museum, but was unable to carry out his intention, as the Vicar of Plumstead had the relics buried privately in the parochial churchyard, and now refuses to reveal their present position. This action of the vicar was discussed at first in a tone of banter, and afterwards with more seriousness, at the last meeting of the Society of Antiquaries. The remains had fortunately been sketched by Dr. Caw, assistant medical officer of the Plumstead Infirmary. It is, however, to be feared that unless the vicar should see fit to relent, or the Home Secretary to order exhumation, these interesting relics will be entirely lost to science.

H.—A note on Saccharine appeared in our issue of Dec. 18th last, page 1193; one on Antifebrine in THE LANCET for Sept. 4th, page 462, and another on Oct. 2nd, page 645.

SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—Dr. Paget Thurstan, while offering an explanation of the cause of sea-sickness, has certainly hit upon a very old and usual mode of treatment. That it is the abdomen, rather than the brain or spinal cord, which requires treatment I feel convinced. On short voyages the best preliminary is, no doubt, a good meal of cold meat, and then in a couple of hours or so the application of a broad belt of webbing or rubber. It appears to me rather the up-and-down pitching movement of the vessel than the side-to-side rolling action which invokes the sensation. The supine position is a distinct advantage, and serves to keep off the sickness more permanently than anything else. Dr. Gowers says that "sea-sickness is not improbably due to the oscillations of the endolymph in the semicircular canals"; but, surely, this oscillates freely enough in ordinary locomotion. The puzzle is, why do some people always suffer and others never? And who are most exempt, the stout or thin, the tight-laced or the rationally dressed?

I am, Sirs, yours faithfully,
Feb. 12th, 1887. J. RUSSELL HARRIS, M.D.

To the Editors of THE LANCET.

SIRS,—Dr. Paget Thurstan's letter to THE LANCET last week is one of great practical value. I have always thought a great deal might be done in the way of alleviating sea-sickness by mechanical means. It may interest your readers to hear how I prevented myself from being ill last time I crossed from Boulogne to Folkestone. I am a very bad sailor. My method was as follows:—I stood up erect in the cabin, near the door, where I was at the same time protected from the weather and had plenty of fresh air to breathe. I kept tight hold of one of the pillars supporting the deck overhead with one hand, and as the boat heaved upwards and down again as it went over a wave I took a few rapid paces, between a walk and a run, uphill as it were. In this manner I deceived my stomach. That organ imagined the motion was due to my own exertions, which it did not object to submit to, and never found out that at the same time that I walked or ran uphill the boat was playing all sorts of tricks with me. I stood with my face in the direction the boat was going. The passage was an unusually bad one, nearly everyone on board being affected; but I escaped. The method I have endeavoured to describe is rather fatiguing, as it involves standing during the whole passage. It is therefore only suitable for a short sea passage. I have tried other mechanical means to prevent sea-sickness, but have never found one equal to this in efficiency for a short passage.

I am, Sirs, your obedient servant,
Richmond-terrace, S.W., Feb. 15th, 1887. HENRY SUTHERLAND, M.D.

To the Editors of THE LANCET.

SIRS,—At page 350 of your last issue is an interesting note upon the above affliction by Dr. Thurstan, who suggests whether a belt that keeps up pressure on the stomach might not be useful. A reference to Section 862 of the "Medical Digest" will show that this plan has many advocates. One gentleman advises collodion applied to the abdomen. Singing has been affirmed to prevent an attack, evidently acting by fixing the abdominal muscles. Lying on the right side is also stated to be a specific.

I am, Sirs, yours truly,
Boundary-road, N.W., Feb. 14th, 1887. RICHD. NEALE, M.D. Lond.

"FISSURED LIP."

To the Editors of THE LANCET.

SIRS,—If those gentlemen who advocate the heroic treatment of paring the edges and putting in harelip pins for fissure of the lip would try keeping the part moist with vaseline or other greasy application, and forbid all sources of irritation, smoking especially, they would find the fissure rapidly heal.—I am, Sirs, yours truly,

T. GRANT LANGHORNE, M.R.C.S., &c.
St. James's-square, W., Feb. 15th, 1887.

THE JACOB TESTIMONIAL.

THE sum subscribed to this fund now amounts to about £431. We are asked by the honorary treasurer to remind gentlemen of their subscriptions promised, in the hope that they will forward them immediately, so that their names may appear in the address about to be presented.

Mr. E. H. Hackett.—The literature of the subject is scattered about in pamphlets and publications. Our own columns have contained a large amount of information on Pasteur's method.

Mr. G. W. Parker.—1. We think not.—2. Scoresby Jackson's work on Medical Climatology might be consulted.

TREATMENT OF DIPHTHERIA.

To the Editors of THE LANCET.

SIRS,—Having regard to the present prevalence of diphtheria, I hope you will allow me to call the attention of the profession to the very valuable and, I believe, specific effects of sulphite of magnesia upon this disease. I was first indebted to Dr. Lewis of Dalbeattie, N.B., for my introduction to the drug, and have used it during the past eight years with unfailing success. I first drew attention to the remedy in a paper I read some few years ago before the Bradford Medico-Chirurgical Society. I use the sulphite in the proportion of 1 ounce to sixteen ounces of water as a gargle every hour (directing the bottle to be well shaken before use, as the substance is but sparingly soluble), a little to be swallowed after each gargling. In children and bad cases I likewise apply the powder direct to the diseased fauces by immersing a damp throat brush in some of the powder, thus being able to get a considerable portion clinging to the brush, which I then apply direct to the fauces, where I leave as much of the powder as possible. I unhesitatingly state that this drug in my hands has been the means of saving several lives. An arrest of the disease may be looked for within a few hours of its use and the commencing disappearance of the membrane within from twenty-four to forty-eight hours. Without at present entering into the theory of the cure, I should like to state that I am of opinion that the comparatively speaking insolubility of the powder is an important factor in its action, and that the object to be chiefly aimed at in its application is to leave as much of it as possible clinging about the throat.

I remain, Sirs, yours faithfully,

Bradford, Feb. 14th, 1887. W. GILCHRIST BURNIE, M.R.C.S.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Lauder Brunton, London; Dr. F. ABSTRACTS OF THE

Erasmus Wilson Lectures

ON

EVOLUTION IN PATHOLOGY.

Delivered at the Royal College of Surgeons of England,

BY J. BLAND SUTTON, F.R.C.S.,

ASSISTANT-SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE III.

REVERSION OR ATAVISM (GER. RÜCKSCHLAG).

MR. PRESIDENT AND GENTLEMEN, — By reversion or atavism is usually understood a tendency in the offspring to resemble its grandparents or more remote ancestors instead of its immediate parents. To the consideration of this interesting and important subject the present lecture will be devoted, but attention will be more particularly directed to reversion as it affects structural aberrations.

Few persons competent to form an opinion on the matter will deny that in the embryological history of a given animal we read a brief epitome of its ancestry—in fact, its evolution. Nothing represents this so forcibly as the following quotation from Von Baer: "In my possession are two little embryos in spirit, whose names I have omitted to attach, and at present I am quite unable to say to what class they belong. They may be lizards or small birds, or very young mammalia, so complete is the similarity in the mode of formation of the head and trunk in these animals. The extremities are still absent in these embryos; but even if they had existed in the early stage of their development, we should learn nothing, for the feet of lizards and mammals, the wings of birds, no less than the hands and feet of man, all arise from the same fundamental form." This striking passage from the writings of the great father of embryology has been rendered more forcible by the efforts of modern investigators in this the most difficult of all departments of biology.

Structural aberrations of congenital origin must be divided into three main classes: 1. Persistent fœtal conditions. 2. The attainment of a functional or more or less full development of structures which for a given animal are normally suppressed during embryonic life. 3. Malformations: spurious atavism. Each of the three classes will be considered in detail.

1. *Persistent fœtal conditions.*—To this class belong the various forms of cleft palate, whether it vary from a bifid uvula to a cleft extending the whole length of the roof of the mouth. In fish the buccal and nasal cavities are a common chamber; in lizards and most birds the hard and soft palates are normally cleft, whilst in the young kangaroo the uvula is bifid. The funicular pouch of the peritoneum is a case in point. Normally it becomes closed in its abdominal segment, leaving the tunica vaginalis testis as an isolated sac. Frequently it fails to obliterate in any of its course. In this respect it conforms to the condition of the pouch found in the majority of mammalia. Up to the present time, although I have examined all the more important mammals specially in regard to this point, I have never yet found the pouch closed. Sometimes it will only admit a thin probe, but in others the index-finger could be easily accommodated in the peritoneal recess. Numerous examples suggest themselves of arrest in development—e.g., malformations of heart, uterus, intestinal canal, &c.

2. *The attainment of a functional or more or less full development of structures which for a given animal are suppressed during embryonic life.*—In my first lecture—that on suppression of parts—a number of examples were given of organs or parts of organs which became arrested during embryonic life, which later on may serve as germs of various pathological growths. In this place we shall have to deal with certain of these structures in a functional condition. It is important for us to bear in mind that, as Gegenbaur points out,[1] "atavism consists not in the existence of a latent germ, but in its becoming perfected and further developed." The facts relating to the os centrale of the carpus, as described in the first lecture, is a good example of what is to be understood by the preceding sentence. It is also essential to bear in mind that in the majority of cases of reversion the atavistic parts do not belong to forms palæontologically remote or systematically far distant. (Hensel, Gegenbaur.) In the case of the os centrale we know that it occurs among the higher apes, for the orang and gibbon present this bone well pronounced in the carpus. The clearest instance, and one which is also interesting, is that furnished by the manus of the horse. It is a well-established fact that Hipparion, the immediate ancestor of the modern horse, possessed three functional toes of the character represented in Fig. 8. Hensel's investigations appear to show that the inner toe was the last to abort when the equine manus assumed the condition shown in Fig. 9. Theoretical reasons would lead us to suppose that if any of these toes reappeared as abnormalities, the one which was the last to disappear would be that most frequently represented atavistically. This is precisely what occurs, and numerous specimens preserved in museums and reported in periodical literature attest the fact. By far the most remarkable of these cases is that reported by Marsh[2] in an important paper on "Horses recent and extinct." Here he gives an excellent account of a case exhibited as the Cuban pony, in which this inner digit had reappeared in a functional form on both hind and fore limbs. The skeleton of a manus of this nature is given in Fig. 9. In such cases as these there seems to be little difficulty in clearly assigning the deformity to atavism; but that the difficulty may not be under-estimated, let the student carefully consider the

FIG. 8. FIG. 9. FIG. 10.

FIG. 9.—The manus of a horse with an extra digit functional. (After Marsh.)

FIG. 10.—The manus of the modern horse. One toe functional.

remarks made further on regarding another mode by which the horse may acquire an additional functional digit. In the spider monkeys the thumb is usually represented by a mixture of fibrous and cartilaginous tissue, yet a perfectly developed thumb is occasionally developed in these quadrumana.

3. *Spurious atavism.*—Twenty years ago, anyone writing upon this subject and regarding abnormalities such as we have been considering as reversions to lower forms would have been looked upon in a very unfavourable light. Fortunately the aspect of things has changed, and the discussion of such matters is admissible even in polite conversation. It is exceedingly necessary to guard against running into the opposite extreme, for there is a decided tendency at the present time, when anything unusual occurs in the conformation of the parts of an animal, to find out some corresponding condition in lower animals, and at once to pronounce it as a reversion. This is, of course, erroneous, and an attempt will be made to bring under notice some examples of this false and unsatisfactory form of reasoning. One of the clearest instances known to me is that abnormality of the stomach called congenital contraction. Why it should be termed congenital is not very evident, since no anatomist or pathologist who has studied this matter or described specimens of this nature makes any mention of such a condition being found in the fœtus or young child. A typical form of the malformation is represented in Fig. 11. We see midway between the pylorus and cardiac extremity of the stomach a contraction which divides the viscus in two distinct parts, causing it to resemble somewhat a rudimentary condition of the complex stomach of

[1] Polydactyly as Atavism. Morph. Jahrbüch, Bd. vi., S. 584. (See also Journal of Anatomy and Physiology, vol. xvi., p. 615.

Digitized by Google

the ruminant, or an approach rather to that of the genus Cervulus. Carefully bearing in our minds that a reversion consists in a reappearance of a lost character, we shall have to show phylogenetically that man's immediate ancestors possess such a stomach; but we know full well that a complex viscus of the character exhibited by the ruminant stomach is an exceedingly specialised arrangement, reaching its maximum among this division of the Ungulata, and in its most complex form confined to it. Certainly on phylogenetic grounds the argument cannot be upheld. Again, in by far the greater number of cases, atavism consists in retention of fœtal characters, and the atavistic type is, as I have been so careful to point out, due to the retention of fœtal characters which attain a functional condition. If during its embryonic stages the human stomach presented such a shape as that represented in Fig. 11, it could easily be understood that in some cases it would be permanent; but this we know full well is not the case.

Phylogeny and embryology are both eloquent in furnishing denial on this subject; therefore it is illogical, and as unreasonable as it is unscientific, to regard this malformation of the stomach as a reversion. We must also be careful not to confound physiological types with reversions. For example: an erectile tumour is structurally similar to the comb of a cock, yet no one would venture to suggest that the nævi which occur so frequently in infants, immediately over the anterior fontanelle, are to be regarded as reversion to a cock's comb.

A like instance is furnished by the submaxillary gland of the armadillo. In this edentate, the duct, soon after it leaves the gland, dilates into a salivary bladder, serving as a reservoir of some capacity. How easy it would be to say that in cysts of the mouth produced by obstruction and subsequent dilatation of the salivary ducts we have a good instance of reversion to the armadillo type. The thing at

FIG. 11.

So-called congenital contraction of the human stomach.

once strikes us as absurd. Take the case of those remarkable bodies found in some of the ganglia or cysts occasionally connected with the tendons of the flexors and extensors of the hand. Now bodies exactly resembling these occur constantly in connexion with the jaws of sharks. Professor Charles Stewart has shown that immediately above the mandibular articulation in the skate there is a recess where concretions exactly resembling the melon-seed bodies are formed and passed down into the joint through a narrow opening. In this instance we may use these as physiological types of the melon-seed bodies found in ganglia, but the latter must not be regarded as reversions. It must not be concluded from this that I object to descend to fish to find reversions; on the contrary, the human body abounds in structures decidedly piscine—e.g., the enamel and dentine of teeth and odontomata, and our primitive cartilaginous skeleton; in the possession of membrane, bones, branchial clefts, and the like. In these cases, however, we can trace them in mammals, thence to reptiles, downwards to amphibians, and so on to fish; but if a character appears in man which, so far as we know, occurs not in the intermediate forms, and especially those closely allied, then objection must be taken to it as being atavistic.

Let me now select an example which will serve to show how much care is requisite in determining reversions. The possession of lanugo by the fœtus, which is as a rule shed *in utero*, is a clear indication of a lost adult character merely persisting in the embryo in obedience to heredity. Occasionally, however, the lanugo, instead of being shed, attains full development. This excessive growth may perhaps only affect a patch half an inch square, but it may extend over half the body, as in Fig. 12. Such overgrowths are known as moles. This is true atavism, for we have only to descend to man's nearest neighbours, the anthropomorphæ, and the truth is evident. But every abnormal hairy patch is not due to overgrowth of lanugo. It has long been known, and Hunter was well aware of it, that when parts have long been irritated, as by the prolonged use of poultices &c., an abundant crop of hair has been produced around the part. But there is a more subtle form of hairiness which leads to some very remarkable speculations.

There is a variety of spina bifida known as "occulta," the chief peculiarity of which consists in the non-existence of

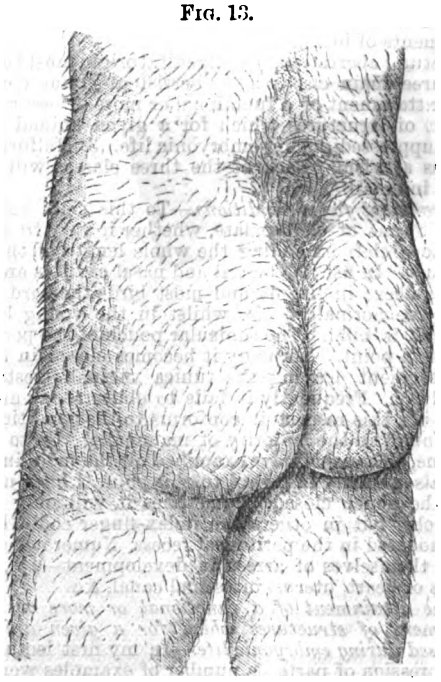

FIG. 12.

A hairy mole on a man. It had become the seat of an epithelioma. (From a drawing presented by Mr. George Lawson to the Middlesex Hospital Museum.)

any external tumour, but a membranous spot may be detected in the vertebral column, as described in the first lecture. Associated with this is some thickening of the membranes, an accumulation of fat, or mixture of fat and striped muscle fibre in relation with the spinal cord. The irritation leads to the development of an abundant crop of

FIG. 13.

Abnormal hairiness of the loins, due to the irritation of a spina bifida occulta. (After Recklinghausen.)

hairs, as shown roughly in Fig. 13, the hirsutes being most abundant in the vicinity of the defect. The case in question was reported by Recklinghausen,[3] but it is not the most perfect one that could have been selected, for a tumour had been removed in early childhood from the patient. However, it serves well to illustrate the point.

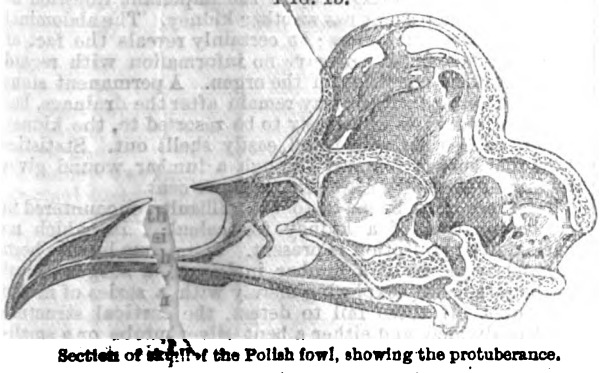
Darwin[4] draws attention to the curious variety of fowls which possess a topknot of feathers, as shown in Fig. 14, familiar to poultry breeders as the Polish fowl. The skull underneath this tuft exhibits a remarkable deviation from the ordinary form seen in fowls. The deformity will be best understood by a glance at the skull of a Polish fowl, shown in longitudinal section in Fig. 15. The summit of the protuberance in the Polish fowl often presents irregular membranous spaces. Virchow[5] regards the cranial deformity as of the nature of a hereditary encephalocele, and the luxurious overgrowth of feathers is associated with it, in the

FIG. 14.



Head of a Polish fowl with feathery tuft. (After Darwin.)

same way that excessive growth of hair is a concomitant of spina bifida occulta in man, and even ordinary spina bifida.

Polydactyly.—Supernumerary fingers and toes constitute a class of malformations which give rise to great difficulty to those who have devoted attention to reversionary phenomena. A very large number of cases of increase in the number of digits has been recorded and carefully described by teratologists, anatomists, and surgeons; the extra digits varying from one or two phalanges, encased in tissues, and hanging by a pedicle from a complete finger, or as a complete finger articulating with, or ankylosed to, a

FIG. 15.

Section of skull of the Polish fowl, showing the protuberance.

metacarpal or metatarsal bone. Darwin was of opinion that supernumerary digits are atavistic in the sense that they are to be regarded as a process of budding similar to that found in the limbs of amphibians. This view, however, has not found favour. In order to find a vertebrate ancestor with more than the typical number of five digits in manus and pes, we should be obliged to descend to fish or such fossil reptiles as the ichthyosauri for types. From such forms to man the gap is too enormous, and the modifications of the limbs so extensive that misinterpretation is unavoidable. It has already been indicated that when atavism occurs, although it may occasionally reproduce a remote ancestral character, it with far greater frequency represents those of its more recent ancestors. If all cases of supernumerary digits are reversions, where are we to go for types with double hands, double feet, and so forth? A broad survey shows that there is a tendency to reduplication in many parts of the body. Thus, in lizards, reptiles, or amphibia double tails are not unknown; even reduplication of the vertebral column occurs, not only in man, but in many vertebrates. Interesting examples of the bifurcation of the axis of a limb have been described by Albrecht in the mud-fish, Protopterus annectans, and in Ceratodus by Howes. A good example of the tendency exhibited by digits to bifurcate is represented in Fig. 16. It is the manus of a horse preserved in L'Ecole Vétérinaire de Lyons. In this case the phalanges attached to the main (third) metacarpal have bifurcated. If these are to be regarded as examples of atavism, we shall be obliged to find animals with two tails, any number of spare digits, or even limbs. To insist that such examples are to be regarded as reversions is certainly inconsistent with sound reasoning.

The following example will serve to show to what extent care is necessary in deciding whether a given abnormality is atavistic or otherwise. In the Teratological Collection of the Museum of the College of Surgeons is the interesting specimen shown in Fig. 17. It consists of the skeleton of the right manus of a horse, with an additional largely developed digit intercalated between the inner splint bone and the middle toe. The second row of carpal bones is preserved, and exhibits an additional bone. The animal was shod on both toes. A superficial glance at once suggests that we have here one of the horse's lost digits reappearing. A critical examination reveals, however, that, if this is a case of atavism, the splint bone on the inner side must represent

FIG. 16.

Bifurcation of the third digit of a horse. (After Chauveau.)

FIG. 17.

A similar specimen. (Museum of Royal College of Surgeons.)

the thumb. This is contrary to what has been already expressed—viz., the parts last suppressed are those most prone to reappear by reversion. If we take the pains to compare this specimen with Chauveau's case represented beside it, there remains very little doubt that it is not atavistic, but a reduplication of the middle digit—in fact, a malformation.

In concluding these lectures, permit me to make the following remarks:—How many have felt, as the yearly total of facts make their appearance in the volumes known as the Transactions of the Pathological Society and Virchow's *Archiv*, that many wearisome details of the minute structure of tumours and other morbid changes are recorded again and again, until it seems that the description of the histology of a diseased structure marks the finality of pathological science. Pathology is sufficiently hampered with isolated facts already, and it is time that those who have the energy and leisure should employ them in searching for some laws whereby to regulate this accumulation, which bids fair to bring discredit on the pathologist. Comparative pathology, studied from the standpoint of evolution, offers every inducement in this respect, and will yield a fruitful harvest to those willing to toil in this fertile field.

Note.—That part of the lecture devoted to "Branchial Fissures and Supernumerary Auricles" appears in full in the January number of the *Journal of Anatomy and Physiology*. The theory advanced to explain the transmission of male or female characters, and a full discussion of the morphology of the prostate, will appear in the Proceedings of the Zoological Society for December, 1886. The discussion regarding parasitic fœtuses in the sacral region, with full illustrations, will appear in the *Gynæcological Journal*, vol. ii. The explanation of "meningocele" in the occipital region was published in *Brain* (October, 1886).

A Clinical Lecture
ON
RENAL SURGERY.

Delivered at the General Hospital, Birmingham, on Nov. 25th, 1886,

BY T. F. CHAVASSE, M.D., C.M., F.R.C.S. ED.,
SURGEON TO THE HOSPITAL.

GENTLEMEN,—The surgery of the kidney has made of late years many and great advances, but there are still practical points open to discussion and to improvement. Some of these I propose to consider with you. As a basis, and in order that the examination may be made more complete, I have selected fatal cases in which post-mortem examinations have afforded opportunities of verifying our diagnosis and discovering sources of error.

CASE 1.—A warehouseman, aged twenty-seven, was admitted to the General Hospital on July 6th, 1886, under the care of my colleague, Dr. Saundby. For three years, on and off, pain had been experienced in the left side, but latterly the pains had been centred in the back.

On admission, there was a slight swelling, more or less lobulated to the feel, and dull on percussion, to be detected in the left flank, extending forward to a point below the umbilicus. An examination of the urine showed that the average daily quantity passed was thirty-five ounces, that the reaction was acid, the specific gravity 1014, and that it contained albumen, blood, and pus. With regard to the pus, Dr. Saundby noted that the quantity was about one-fifth of the deposit in a conical glass—viz., two ounces out of ten. At this stage of the proceedings the patient declined to submit to any operative treatment, and left the hospital on July 12th.

He was readmitted on August 4th, as the tumour had increased in size, and a few days later came under my care. After consultation, as a renal calculus was suspected to be the cause of the swelling, it was decided to explore the kidney through a lumbar incision. This was accordingly done on Aug. 10th. On exposing a portion of the viscus, it appeared firm, but somewhat tense. The organ was incised, and more than eighteen ounces of purulent fluid were evacuated. The forefinger introduced into the wound, after a little search, detected this rough tuberculated calculus, somewhat triangular shaped, weighing 30 gr. It was removed, and careful examination, made by my own finger and that of my colleague assisting, failed to detect anything further. I was then warned by the anæsthetiser that the patient was much collapsed, and that the operation had better be concluded as rapidly as possible. The kidney was therefore irrigated by means of a tube introduced into the wound with a weak warm solution of boracic acid, and a large drainage-tube inserted. The whole operation only lasted half an hour, but the patient when removed to bed was in a state of extreme collapse. After the application of restoratives his pulse improved somewhat, but life was with difficulty maintained. Great pain was complained of in the region of the wound two hours after the operation, and one-eighth of a grain of morphia was administered subcutaneously. The discharge was profuse, and necessitated a change of the dressings eleven hours after the operation. After this the cold perspirations and other symptoms of shock seemed to be improving, but sixteen hours after the operation he suddenly but quietly died. A few ounces of bloody urine were passed per urethram between the time of death and the completion of the operation. Unfortunately the friends declined to permit any regular examination of the body. The left kidney had therefore to be removed by merely enlarging the lumbar wound. The condition of the other organ could not be ascertained. The kidney here presented shows total disorganisation; it is enlarged and divided by septa into numerous abscess cavities. Practically no cortical substance exists. From the recesses of the pouches numerous small calculi (about fifty) were washed out. Here are some of them, varying in size from a millet-seed to a pea. The organ itself was hardened in spirit for a month and then laid open. Another and a larger calculus than the one removed was disclosed firmly impacted in the top of the ureter, and virtually obliterating this tube. Its weight was 38 gr.

In this case surgical treatment was too long delayed. To obtain the greatest possible benefits from operative measures, renal calculi must be sought for and removed before destruction and consequent abscess have resulted. Doubtless, reference to cases within one's own knowledge, and to the literature of the subject, shows that a suppurating kidney may contract and heal marvellously well after efficient drainage has been established and all irritants removed, but then it can only work as a very much damaged organ, while an earlier operation may be the means of restoring its powers to nearly normal. Surgically speaking, the signs and symptoms most to be relied upon for the diagnosis of renal calculus where no tumour exists, the patient being otherwise healthy, are the following:—1. The presence of blood in the urine, especially after exertion. 2. Unilateral pain passing down the ureter towards the testis. 3. Pain elicited by deep-seated pressure in the lumbar region, between the last rib and the iliac crest, just external to the erector spinæ muscle. 4. The presence of uric and oxalate crystals in the urine as revealed by the microscope. With such symptoms the surgeon is fully justified in making a lumbar exploration of the kidney, as he is also, I think, in those cases of chronic nephralgia depending on uncertain causes which milder means and medicines have failed to remedy. Even if no stone be detected, instances are on record in which the patient has obtained prolonged relief. The explanation may be that the division of the lumbar tissues and of the renal capsule lessens the existing tension.

The shock following a surgical examination of the kidneys varies very much. In some instances I have seen it marked; but in an individual otherwise healthy and free from any renal suppuration it is generally slight. The death of this patient was somewhat of a surprise, and it is a matter of regret that a complete post-mortem examination was not permitted, in order that the conditions of the opposite viscus might have been ascertained. According to the statistics of Professor Gross, based upon seventy-two cases of incision and drainage, thirteen fatalities occurred. In 32·20 per cent. of the remainder a renal fistula resulted.

In suppurative lesions of the kidney permitting operative interference it is, I think, better that nephrectomy and drainage should first be undertaken, and the course of events watched. The surgeon is then afforded an opportunity of seeing the effects produced upon the opposite kidney. If the pus soon diminishes and disappears from the urine, the organ is probably sound. The lumbar incision, at the time of the operation, throws no light upon the important question as to whether the patient has another kidney. The abdominal does not assist much more; it certainly reveals the fact of bare existence, but it can give no information with regard to the working condition of the organ. A permanent sinus of a troublesome nature may remain after the drainage, but if nephrectomy has ultimately to be resorted to, the kidney is more or less shrivelled and easily shells out. Statistics show that such a removal through a lumbar wound gives the lowest mortality rate—viz., 9·33 per cent.

Reference must be made to the difficulty encountered in an examination of a kidney for calculus in which no marked disorganisation is present. The viscus having been exposed by means of a lumbar incision, the surgeon must not be satisfied by exploring merely with a series of needle punctures. If these fail to detect, the cortical structure must be divided, and either a bent silver probe or a small-sized child's sound introduced into the pelvis of the organ, and the whole of its interior investigated. This incision need not be large, and may be made either at the outer border, or, as suggested by my friend Mr. Lloyd, at the lower edge of the organ. This little wound, it is true, causes a slight hæmorrhage, but it can be easily restrained by sponge pressure. In a case reported by Dr. Tiffany[1] the hot blade of the thermo-cautery was successfully substituted for the knife in order to avoid this bleeding.

CASE 2.—On May 12th, 1885, I exposed the right kidney of a woman, aged twenty-two, who had suffered from pyuria for nearly three years, and at times from pain referred to the regions of the right kidney and ureter. The pus in a conical urine glass formed a deposit of one inch and a half, and the patient was much emaciated. I "needled" the kidney in nearly a dozen places, either to find

[1] Transactions of the American Surgical Association, vol. iii., 1885.

Digitized by Google

a stone or to tap an abscess. The patient suffered a good deal from shock, but recovered from this to sink later on from exhaustion.

At the necropsy, on section of the right kidney, an abscess cavity the size of a walnut was found at the head of the organ, occupying the portion of three pyramids and their expanded medullary substance. This abscess cavity communicated with the ureter. To the top of one of the pyramids a small phosphatic stone was found adhering. The capsule of the organ could be readily removed, and its surface was smooth and pale. Numerous small abscesses could be seen in the cortex. The lower portion of the kidney looked fairly healthy, and, although pale, the cortical substance was of good thickness and consistence. The ureter was greatly thickened and adherent to surrounding structures; its lining membrane was thickened and studded with minute soft bodies the size of a millet-seed, intimately adherent to, and apparently in the substance of, the mucous coat. The opening into the bladder was unobstructed. The left kidney weighed 6 oz., and was deeply congested, but the pyramids appeared normal. The bladder was much contracted.

At the time of this operation I did not fully appreciate the necessity of incising the cortex and sounding the pelvis in those cases where the exploring needle failed to detect any abnormality, and, as a consequence, a fair-sized abscess and a small piece of stone remained undetected. For the want of a sufficiently thorough examination of the pelvis of explored kidney by means of an incision and a sound I have no doubt that other operators have met with the same ill success that I did in this instance. The ultimate result would probably have been the same; but the condition of the urinary tract, as revealed by the sectio cadaveris, proves the uselessness of resorting to nephrectomy in cases of so-called tubercular kidney. The affected organ may be removed; but the disease is present in other parts of the urinary apparatus, and the whole disease is not removable. This thorough examination of the kidney pelvis by incision of the cortex is a decided advance, but may sometimes prove fallacious.

CASE 3.—The enlarged kidney here shown is the right viscus of a man, aged thirty-one, who had suffered with marked symptoms of renal calculus for ten years. Through an oblique lumbar incision I failed with needling to detect any stone. The cortex was therefore incised for three-quarters of an inch near the outer border of the organ, and with a large bent probe I explored the pelvis, as was thought at the time, most thoroughly and effectually, yet no calculus was detected. Unfortunately the man died some days after the operation with symptoms of septic poisoning. Plenty of urine was passed after the exploration, and at the end of the second day most of it, to the naked eye, was free from blood.

The following is the report of our pathologist, Dr. Crooke:—"On introducing the hand into the incision in the right loin, the kidney could be felt, and an incision into its substance, through which the forefinger could be pushed for about an inch. On removing the abdominal viscera, the right kidney was seen in position, lying somewhat loosely in its renal cushion, and greatly enlarged. Coloured water injected through the wound distended the peri-renal cellular tissue and oozed simply by force of pressure through the peritoneum into the peritoneal cavity, but there were no evidences whatever of any opening into the peritoneum. Right kidney enormously enlarged, weighing 1 lb. 3 oz., and measuring 9½ in. by [illegible] in. The pelvis was extensively dilated and sacculated, its walls considerably hypertrophied, and its lining membrane smooth and shining; with it communicated a considerably dilated and hypertrophied ureter. Lying at the bottom of the lowest sacculus, into which opened the ureter, was a large flattened convex stone, measuring 1⅞ in. by 1⅛ in., and weighing 288 gr. Besides the large stone, eight smaller ones, brownish in colour and all facetted, were found; these weighed together 30 gr. The kidney substance, which was uniformly hypertrophied, looked fairly healthy and normal. All that remained of the left kidney was a small thickened and dilated sac filled with a turbid secretion; at the upper part there were a thin crust of atrophied renal tissue and several small cysts. Intestines: Walls thickened, and somewhat sodden with œdema. The coils were much distended with gas and liquid yellow fæces; the peritoneal coat showed here and there the lines of hyperæmia indicative of early peritonitis. The parietal peritoneum was also hyperæmic in patches, especially over the region of the right loin and right abdominal wall. The bladder and rectum were normal. The heart weighed 15 oz. The left ventricular wall was much thicker than normal, and generally hypertrophied. The valves and cavities were normal. The bases of the lungs were somewhat congested and œdematous, the upper lobes were quite normal."

Now, at the time of the operation the tip of my own forefinger and that of my colleague assisting passed into a cavity which was considered by us both to be the pelvis of the kidney, and a probe travelled freely upwards and downwards in this space. As a matter of fact, as you now see, the finger and the probe never reached the pelvis, but were separated from it by its lax hypertrophied lining membrane, and the instrument in its course separated this thickened tissue from the cortex without entering the interior of the organ. If in this particular instance the exploration had taken place through an abdominal incision made at the edge of the rectus muscle, there is little doubt that the stone would have been readily detected and removed; as it was, owing to the great enlargement of the viscus, the sulcus containing the calculi lay sheltered in the upper part of the pelvic cavity, and the incision into the renal substance was more than six inches away from the object of the search. The features of interest in the whole case are so numerous and abnormal that in the present imperfect state of renal surgery they appear worthy of special note.

A few words on those cases in which nephrectomy may be performed. Professor Gross, in an able paper[2] showing a wide range of research on this subject, says: "From an extensive acquaintance with the literature of the subject, I have been long convinced that the kidney has been too frequently removed." This is very probable; and in our zeal to test the efficacy of a new operation for the relief of very painful disorders perhaps a few kidneys have been sacrificed. But now that Professor Gross can present a list of 233 cases, and tabulate the diseases, the operation performed, the number and causes of death, together with, in many instances, the results of post-mortem examinations, I think surgeons are in a position to judge more or less accurately what cases are fitted for the operation and what are unsuitable. The statistics show that the lumbar operation is safer than the abdominal. I would not say that on this account it is *always* to have the preference, as due allowance must be made for the nature of the case and the dexterity of the particular operator; but in the majority of instances it is the best operation. It may be resorted to, *after* nephrotomy and drainage have failed to relieve, (*a*) in suppurative lesions depending upon a local irritant, (*b*) in hydronephrosis, and (*c*) in traumatic rupture of the kidney. The operation is also justifiable (*d*) in cases of painful floating kidney, when the attempt to fix the organ has failed and the symptoms are still urgent (the abdominal method to be preferred); and (*e*) for any very troublesome fistula, either renal or ureteral. Nephrectomy is a very doubtful expedient—in fact, I believe it to be contra-indicated in (1) tubercular disease, (2) carcinoma of adults, and (3) sarcoma of children.

CASES OF PERITONITIS.

BY JAMES F. GOODHART, M.D., F.R.C.P.,
PHYSICIAN TO GUY'S HOSPITAL AND THE EVELINA HOSPITAL FOR CHILDREN.

THE subject of peritonitis is not one upon which there is anything new to be said, nor one into which any novelty of handling can be well introduced; but it is one which presents points of difficulty in practice which are weighty if they are but few; and some of these will bear reiteration, even allowing that we are not all agreed upon their importance or their bearing. I do not, of course, propose to deal with the subject of peritonitis in all its aspects, but only to touch upon some few of the more salient and, to my mind, disturbing elements in the matter of diagnosis and treatment. I shall probably best carry my readers with me if I say that the points to be insisted upon mostly concern suppurative peritonitis, and if I let cases as far as possible tell their own tale.

Some short while ago I saw a young married lady with what at first seemed to be like intestinal obstruction. She

[2] American Journal of Medical Sciences, July, 1885.

Digitized by Google

was six months pregnant, and her bowels were by habit much confined. The constipation had been worse than usual, and she had taken some pills to overcome this without medical advice. These had caused a great deal of pain, but had produced an evacuation at first scybalous and then loose. She vomited soon after the aperient had acted, and continued to do so, and for five days after she passed nothing, not excepting flatus. The abdomen had become much distended and the vomit had assumed a stercoraceous appearance. But there was another element in the history of the case which is important to the formation of a diagnosis. She had had during two or three years repeated attacks of pain in the right iliac region, with considerable thickening there at times; and for this she had been obliged more than once to take to her bed and couch for two or three weeks at a time. She had had an attack of this kind two or three months before her last illness, but was supposed to be now well of this. She had a most pinched and collapsed appearance, her eyes being sunken, her voice low and hollow; pulse 120 to 130, of good volume; the tongue foul. There had been no vomiting since the morning, but a constant tendency to retch. The bowels had acted fully that morning. *The temperature was normal.* The abdomen was distended with flatus, but it was quite soft and easily palpated. There was, perhaps, slight induration in the right groin, not much, and some tenderness in that region. She vomited while I was in the house, the vomit being a dirty-brown thick fluid, but having no offensive smell. Now, this case much resembled a case of intestinal obstruction, and all the more closely from the fact of the existence of pregnancy. The diagnosis rested upon the constipation, the vomiting, the distension of the abdomen, and partly, I think, upon the normal temperature. But none of these things are reliable means of distinction between the paralysis of peritonitis and mechanical obstruction; and the old history that existed of cæcal inflammation, or rather of inflammation in that region, made the peritonitic hypothesis far more probable. I heard of her from time to time during the next few days, the account always being that her temperature was normal; there was a yeast-like diarrhœa, which was difficult to control, but that, on the whole, she was doing well. The diarrhœa went on, and caused considerable anxiety. Then it was controlled, and again she was doing well, with a "but"—"the pulse kept up so quick," and on the ninth day it became unsteady, and the patient sank. The necropsy revealed what was expected: some old disease in the right broad ligament and in the cæcal region, with a local abscess and general suppurative peritonitis.

With this case let me tell of another. A girl of thirteen, of healthy but neurotic parentage, was quite well till a certain day, and she then complained of pains in the stomach, but nothing much, and no notice was taken of it. Next day she was at a children's party, and the same evening she was decidedly unwell and had much more pain. The next day she was sick several times, but it was supposed to be a mere bilious attack, and no medical man was called in until the fifth day. During all this time she had been vomiting—a decidedly illegitimate extension of the meaning of "bilious,"—and she had also marked tenderness in the right iliac region. In two or three days after her medical man first saw her she still continued to vomit, and the bowels were confined. She then had two or three doses of castor oil, after which she had what was described as "not diarrhœa, but a continuous oozing from the rectum." This had been considered to be the result of nervous exhaustion, it being argued that the absence of pyrexia, which had been a notable feature throughout, negatived the existence of inflammation. I did not see her until the twenty-sixth day of her illness. I had heard the whole history, and the special object of my visit from the parents' point of view was to suggest something to control the diarrhœa. They rested on the idea that if only the food would lodge somewhere and become digested, instead of running out at one end as fast as it was put in at the other, the child would quickly rally. But the history I have given seems to me all too plain, except in one respect to be mentioned directly. I could not doubt that the case was one of typhlitis and peritonitis, and the latter all the more ominous in that its symptoms had been somewhat masked, and that it was now associated with diarrhœa. The child was not pinched and hollow-eyed like a bad case of peritonitis, I must admit, but she had a tense moderately distended abdomen, lay with her legs drawn up, and the muscles of the abdominal wall were exceedingly irritable. In this case I was uncertain whether there was any thickening in the cæcal region, but I thought I could detect something. No complaint of pain in the abdomen was made now, but there was much in the chest. The temperature was 103·4°, and the pulse 140; the lower two-thirds of the left side of the chest were dull, and there was a dry rub round the diaphragmatic edge in front. The heart sounds were excessively muddled and murmurous, but there was no decided murmur, pericardial or other. The view I took of the case was that there had been peri-typhlitis, general peritonitis, quite possibly suppurative, and extension of the inflammation to the left pleura, and possibly to the pericardium also—a condition obviously of the gravest possible danger. I must candidly admit that the medical gentleman in attendance—of great ability, and, as years go, of larger experience than my own—was not very ready to concur in this opinion; but I cannot even now see any other alternative which gives nearly so adequate an explanation of the later complications as the diagnosis above stated.

Great stress was laid upon the absence of fever in this case, as in the last, but it is untrustworthy as an indication if taken by itself. In the first case I have narrated, a post-mortem examination demonstrated the existence of diffuse suppurative peritonitis, and the temperature was never above normal; and the second case appears to have been like it. I have repeatedly seen the same thing in hospital practice; and whether from acute plastic peritonitis—as is well known—or suppuration in the peritoneum, the temperature may give no sign. I do not say that it never does; I will not even say that in the majority of cases it never does. I think it is the other way; but the temperature of peritonitis is an uncertain one, and in a good number of cases it is not raised. But this question of temperature is worth consideration in another way. These cases simulate intestinal obstruction—nay, to speak more truly, they often are cases of intestinal obstruction, but it is the obstruction of paralysed peristalsis, not the mechanical obstruction of volvulus, band, and so forth. But what we have to determine—and it is most important to determine—is, which of these conditions exists. If a volvulus or internal hernia be present, the sooner the condition be relieved by the surgeon the better. Well, now, I believe the temperature will sometimes help us. A few weeks ago I saw a case with Dr. Culver James where this point, rightly or wrongly, greatly determined our decision. A healthy youth of seventeen was suddenly taken with vomiting and abdominal pain after his tea. He had had nothing of a notably indigestible nature to eat. He continued to vomit, and next day walked to see Dr. Culver James at his own house. The bowels were confined; an enema on the third day produced a copious ordinary lumpy stool; after that the rectum remained empty, and no flatus passed for more than twenty-four hours. The temperature was 101·5°. Here, then, was a case of acute pain, vomiting, and constipation. So far it might well have been either some internal hernia or a case of local peritonitis. There was no decided local thickening, although Dr. James had at one time felt a something in the cæcal region, to which spot all the pain was referred. We, however, agreed that the malady was probably inflammatory and typhlitic, because of the pyrexia and because of the comparatively moderate urgency of the symptoms. The subsequent progress of the case, I think, confirmed this view. He continued to vomit occasionally, but the rectum slowly filled with fæcal material, showing that there was paralysed action, and not obstruction. The temperature fell, the bowels then acted daily, and he seemed almost out of the wood. Suddenly, although he had been most carefully tended and treated, in the disappointing way these cases sometimes terminate, at the end of ten days the temperature ran up again to 103°; sickness again came on; there was more increase of pain in the abdomen, accompanied by distension; the pulse became peritonitic, and he died within a few hours of acute peritonitis. By no powers of persuasion could we get a post-mortem.

(To be concluded.)

AT the annual meeting in connexion with the Bideford Infirmary and Dispensary on the 17th inst. it was reported that the total cost of the new hospital will be £2135, and of this a sum of £1711 has already been collected. The new buildings will be opened on the 31st prox.

ON

DISPLACEMENT OF THE INTER-ARTICULAR CARTILAGE OF THE LOWER JAW, AND ITS TREATMENT BY OPERATION.

BY THOMAS ANNANDALE, F.R.S.E.,
REGIUS PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF EDINBURGH

THAT the proper movements of the temporo-maxillary joint may be interfered with by conditions inside the articulation is a fact recognised by all surgical authorities. That a displacement of the inter-articular cartilage—the "subluxation" of Sir Astley Cooper—may be one of these conditions is also recognised. But most modern works on surgery describe this affection as being generally due either to relaxation of the ligaments of the joint allowing a too free movement, or to inflammatory changes of a simple, gouty, or rheumatic nature. Heath[1] writes upon the subject thus: "It is an affection occurring principally in delicate women, and has been thought to depend upon relaxation of the ligaments of the joint permitting a too free movement of the bone, and possibly (though this is conjecture) a slipping of the inter-articular cartilage." Believing with Mr. Heath and other authors that inflammatory results may cause interference with the movements of this joint, I feel further convinced that, as in the case of the semilunar cartilages of the knee, the inter-articular cartilages of the temporo-maxillary joint may become displaced either from a sudden tearing of their connexions or from a gradual stretching of them.

But the chief object of this short paper is to advocate a new method of treating by operation cases of this condition which resist counter-irritation and the other means usually advised, and in which there are symptoms of a too free movement of one or both of these cartilages. The operation is upon the same principle as that which I have described and successfully carried out in connexion with the displacement of the semilunar cartilages of the knee-joint. The method is as follows:—An incision slightly curved, about three-quarters of an inch in length, is made over the posterior margin of the external lateral ligament of this joint, and is carried down to its capsule. Any small bleeding vessels having been secured, the capsule is divided, and the inter-articular cartilage is seized, drawn into position, and secured to the periosteum and other tissues at the outer margin of the articulation by a catgut suture. The following two cases illustrate the condition, and also the good result obtained by the operation suggested.

CASE 1.—Mary M'C——, aged thirty-eight, was admitted into my wards on March 2nd, 1886. Nine years before her admission she injured her temporo-maxillary joints during an attack of vomiting. The joints remained "locked" for a few minutes, but after a little manipulation she herself put the condition right. Ever since this time she has suffered great discomfort in the joint upon the left side, for whenever any extra movement of the jaws was made this joint became fixed, and remained so until she had practised some manipulations, when movement returned. Frequently also, when she tried to open her mouth, she found that she could only do so to a limited extent, but by using the manipulations the proper separation of the jaws was completed. On March 12th an incision was made over the left temporo-maxillary joint, and, its capsule having been divided, the inter-articular cartilage was found to be loosened from its attachments, and much more movable than usual. The cartilage, having been seized with artery forceps, was drawn into position, and a catgut suture passed through it and the periosteum and other tissues at the outer margin of the joint. The wound healed rapidly, and she left the infirmary on March 25th. At this time the movements of the joint were natural, and she could close and separate the jaws perfectly, without any locking or catch.

CASE 2.—Ann M——, aged eighteen, admitted on Jan. 20th, 1885. Two years before admission, the patient when yawning found her jaws fixed. After a little manipulation she was able to close the jaws, but with a "click" on the right side. Since then she has suffered from pain and stiffness upon the left side, and the movements of the joint were constantly interfered with by something "slipping" in it. She had been treated by blistering and other remedies without obtaining any relief. On July 23rd the usual operation was performed, and the left inter-articular cartilage, being found loosened, was stitched in position with a catgut suture, as in the former case. The wound was healed at the end of a week, and she left the infirmary on July 31st, with perfect and proper movement of the jaws.

PHOSPHATIC DIABETES.[1]

BY CHARLES HENRY RALFE, M.D. CANTAB., F.R.C.P.L.,
ASSISTANT-PHYSICIAN, LONDON HOSPITAL.

AMONG the numerous investigations that have engaged the attention of physiologists during the last fifteen years, few yield in interest and importance to the study of the part played by the inorganic constituents of the body in histogenesis, and their influence in producing the daily and hourly variations which occur in the chemical composition of the secretions. Although this branch of animal physiology is only partially developed, yet our knowledge in this direction is steadily and constantly advancing, and the advance will be more rapid when it becomes clearly perceived how greatly minute variations of the inorganic constituents conveyed by the blood plasma to the cells influence for good or evil the processes of nutrition going on in the tissues. I can here only glance at some of the more important facts that have been established in this direction, and touch only on those points which are most closely related to the subject matter of the present paper.

Twenty years ago it was stated in most text-books that inorganic substances passed unaltered through the body, and that the same weight of saline constituents was recoverable from the urine and fæces as was introduced during the same period with the food and drink. The first advance on this simple view was made when it was discovered that chloride of sodium was retained in the body, and consequently disappeared from the urine, in certain diseases attended with increased cell-formation; and that even under normal conditions only four-fifths of the common salt ingested left the body as such, the remaining fifth being decomposed and altered in constitution within the system. Further researches led to the important discovery that whilst inorganic salts pass with immense and usually uniform rapidity into the circulation, and thence to the tissues, their discharge is by no means so regular, and they are detained for very unequal periods, which apparently depends on the need of the tissue to which they are supplied. Thus both Hoffmann and Lascar have shown that, however great the tendency of the alkaline bases is to combine with acids and acid salts, these cannot be withdrawn from the alkaline blood, but are powerfully withheld to maintain its alkalinity. And this fact is illustrated by what occurs in scurvy, for, as I pointed out in 1877,[2] and it has since been corroborated by Zuelzer,[3] as soon as the alkaline carbonates cease to be supplied by means of vegetables, the alkaline phosphates begin at once to disappear from the urine, evidently to maintain the alkalescence of the blood diminished by the withdrawal of the alkaline carbonates. In connexion with this it is interesting to notice that Dr. Gee[4] has likewise called attention to the remarkable fact that in ague, on the days of the paroxysms, the phosphates almost entirely disappear from the urine; and although Dr. Gee has not attempted an explanation of the phenomenon, still it is not unlikely that this is again an instance of a salt being withheld to supply a special requirement, whilst another is being discharged in excess; for it is important to notice in connexion with this withdrawal of phosphoric acid during the ague fit that the chlorides are at that time eliminated in considerable excess. It would be easy to multiply examples, but enough has been said to emphasise the importance of the *rôle* played by the inorganic substances in the economy.

Of all inorganic constituents phosphorus has always been regarded as holding the prominent position. When first separated from the urine by Brandt (1669) it was at once hailed by the physiologists of the day as the "blood of

nature," and quacks held forth that their "wonderful shining pills" contained the true elixir of life. The discovery, at the commencement of this century, by Wollaston that certain calculi were composed, some wholly, others in part, of phosphate of lime and ammonio-magnesium phosphate, led to further inquiries as to the conditions that cause the deposition of these substances in the urinary passages; and to Dr. Prout and Dr. Golding Bird we are indebted for the discovery of many important facts connected with phosphaturia. Unfortunately at first sufficient care was not taken to discriminate between the conditions which led to the deposition of phosphate of lime, and that which caused the precipitation of ammonio-magnesium phosphate; and as the latter was often associated with paraplegia, or followed after spinal injury, the idea that phosphaturia was caused by irritation or disease of the nervous system became dominant, and it was taught that the phosphates in the urine were derived chiefly, if not entirely, from the phosphorus of the disintegrated nervous matter. Dr. Owen Rees was the first to combat the view that phosphaturia was caused in all cases by excessive elimination; and pointed out that so far as deposition of triple phosphate was concerned, it might be accounted for by the secretion of abnormal mucus, which, owing its alkalinity to fixed alkali when mixed with urine, united with the acids of the ammoniacal salts and set free ammonia, with consequent deposition of ammonio-magnesium phosphate. Dr. Bence Jones went further than this: he showed, first, that causes of the deposition of the triple phosphate were due entirely to local conditions, which brought about an ammoniacal state of the urine from decomposition of the urea; and the admixture of calcium phosphate with the triple phosphate (mixed phosphates) was caused simply by precipitation from alkaline urine, and not due to the presence in excess of the phosphates themselves. Moreover, in that form of phosphaturia in which calcium phosphate was deposited alone from the urine, he declared the deposition was caused solely by precipitation from urine whose alkalinity was due to the presence of fixed alkali. Besides this, he stated that no increase of quantity in the amount of phosphates in the urine takes place in spinal diseases; nor in chronic diseases of the nervous system generally; nor in chronic cases of general paralysis, mania, or melancholia; nor in chronic diseases in which the nervous system is not specially affected; nor in fevers, or acute inflammations of fibrous, muscular, or cartilaginous tissues; and that the only decided increase of the phosphates noticed occurred in acute inflammation of the brain substance, not of the membranes unless the brain was likewise affected. He also stated that there was not the least reason to believe that there was any constitutional state specially characterised by an excessive excretion of phosphates, and that the so-called phosphatic diathesis was simply alkaline urine.

These views have been generally accepted in England, and the teaching as laid down in leading modern text-books is that the phosphaturia in which calcium phosphate is solely deposited depends on urine alkaline from fixed alkali, and denotes nothing more than some disturbance of digestion in which the *alkaline tide* of the urine becomes exaggerated; that the phosphaturia in which both kinds of phosphates are deposited depends on urine alkaline from volatile alkali which arises from decomposition of urea in the urinary passages, and which is mainly brought about by local conditions; and, lastly, that the excretion of phosphates, even if in excess, has no special pathological significance. In Germany, however, the importance of the excretion of phosphoric acid has attracted more attention; for whilst observers there admit the facts connected with the deposition of phosphates from alkaline urine both fixed and volatile, they maintain that the study of the daily variations of the amount of phosphoric acid, especially as regards its relationship to the excretion of urea, has an important bearing on various questions connected with tissue metabolism, both normal and abnormal. They have shown, further, that Dr. Bence Jones was mistaken when he stated that no excessive elimination took place in chronic nervous disorders, since it is exactly in this class that the greatest increase has been found, especially in "depressed states." Besides this, they maintain that the fact of there being no absolute increase in the excretion of phosphoric acid does not disprove the view of an increased elimination of phosphorous bodies, since they have very conclusively shown that in many nervous affections phosphorus appears in the urine, not in its fully oxidised state as phosphoric acid, but as lecithin, or as glycerine phosphoric acid. In France Professor Teissier of Lyons, who has paid considerable attention to the physiological conditions which regulate the elimination of phosphoric acid from the body, has described a condition to which he has applied the term, "phosphatic diabetes," and which consists in the continuous and excessive discharge of phosphates by the urine, attended with symptoms not unlike those of saccharine diabetes. This condition, Professor Teissier states, may be observed (1) in certain functional derangements of the nervous system; (2) it may precede or accompany certain affections of the lungs; (3) it may coexist with glycosuria, or alternate with it; or (4) it may run a course distinct by itself. As I have seen a few cases like those described by Professor Teissier, I have ventured to bring them before the consideration of the Society to-night, in the hope that by attention being drawn to the subject it may be more closely investigated than has hitherto been the case. In relating the cases, I intend to keep to Professor Teissier's classification; not because I altogether agree with him, but for convenience of reference and discussion. And again, in order to obviate the necessity of constantly reading figures of analysis and referring to the amounts of phosphoric acid passed, I may say that no case has been admitted to this series in which the daily average excretion has fallen below two-thirds more than the ordinary normal secretion.

GROUP 1. *Increased excretion of phosphoric acid associated with disturbance of the nervous system.*—The first case is that of a lad, aged sixteen, who was under my care at the Seamen's Hospital in 1876. When admitted he was in a stupid, semi-comatose condition, much emaciated and very feeble. He was passing considerable quantities of slightly acid urine of medium specific gravity containing a slight trace of albumen, but no sugar. In this case the excretion of phosphoric acid was for some time more than double what a lad of his age and weight (9 st.) should pass under ordinary circumstances. No other morbid conditions could be detected; and, after remaining in bed several days, he gradually brightened and began to gain in weight, whilst the excessive excretion of phosphoric acid fell at first to two-thirds and then to one-half more than the normal, at which point it remained till the patient's discharge.

The next case is the lad whom I have brought before the Society to-night. I first saw him in September of last year, in consultation with my friend Dr. Allt of Clapham. The symptoms were considerable and progressive emaciation and a dull lethargic condition, sitting for hours by himself doing nothing, and being roused to speak only with great difficulty. He also obstinately refused at times to take food, which had to be forced on him. No other special morbid condition could be detected. The urine was highly acid, normal in quantity, about forty ounces, with a specific gravity of 1036. The urea was in excess, whilst the amount of phosphoric acid was in considerable excess. Complete rest (either in bed or on a sofa), country air, and massage were advised, and for treatment bromide of potassium, nux vomica, and cod-liver oil. The patient then went to Melton Mowbray, where he has been under the care of Dr. Powell, who has kindly from time to time kept me informed with regard to the case, and sent me samples of the twenty-four hours' urine to analyse. The treatment has been varied from time to time, mineral acids with strychnine and small doses of opium being that generally persisted in. Till just before Christmas no improvement was manifested, though the patient was certainly less dull; still the high specific gravity was maintained, and the emaciation was very marked. But about three weeks since the patient began to take his cod-liver oil more regularly, and Dr. Powell soon after noted an increase of weight, whilst the excretion of phosphoric acid fell to 3·9 grammes daily, which for the boy's age and weight still represent very nearly two-thirds more than what the normal excretion should be. I may mention that the patient has been at times troubled with boils.

In another case, in which the patient was passing on an average six grammes of phosphoric acid in the twenty-four hours, a small syphilitic growth was found post-mortem at the base of the brain, with some softening of the brain substance round. As, however, there was an intense polyuria amounting to thirteen pints a day, with a specific gravity of 1002 to 1004, I think some of the increase in this case was due to the washing out of phosphoric acid from the tissues

Digitized by Google

by the drainage going on through the body, and is not an instance of increased tissue metabolism.

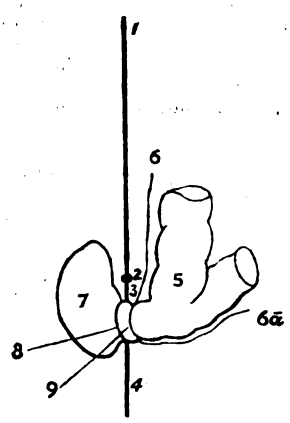
GROUP 2. *Increased excretion of phosphoric acid associated with pulmonary disease.*—I have met with three cases. The first, a young gentleman, aged nineteen, who was living in London engaged in mercantile pursuits. When I first saw him there was nothing definite to be made out, except that he complained greatly of lassitude and aching pains round his loins. A careful examination of the chest revealed no disease. The urine was normal in quantity, of high specific gravity, very acid, but occasionally becoming alkaline, when it deposited dense masses of calcium phosphate. The urea was in excess and the daily elimination of phosphoric acid considerably above the normal. This patient was frequently troubled with boils. As he became weaker, and it was evident that London life did not suit him, I advised a sea voyage, which I believe he took. Three years later I heard through a friend that the patient was dead, that two years after I had last seen him symptoms of pulmonary disease manifested themselves, which ran a rapid course and terminated fatally.

The second case was sent me by Surgeon-General Balfour. A gentleman, aged forty-nine, who had spent the greater part of his life abroad, was in 1881 troubled with polyuria, passing about eighty ounces of urine a day. This urine was acid, and had an average specific gravity of 1015; there was some excess of urea, and a considerable increase in the daily excretion of phosphoric acid. He suffered from thirst, loss of flesh, and complained of severe rheumatic pains in the loins and pelvic regions; he also was troubled with boils. On my advice he left London and went to reside at Brighton, and shortly after the urinary flux fell from eighty to sixty ounces, whilst the excessive elimination of phosphoric acid was also reduced. After he had resided at Brighton about a year he began to suffer from cough, and again to lose flesh. Before this he had exhibited no signs of lung mischief, but now on examination I found a patch of consolidation in the apex of the right lung. As it was then autumn I advised him to winter either in the south of France, Algiers, or Sicily. He chose the latter, and I heard nothing more of him till the other day, when Dr. Balfour told me he died the next year at Naples of typhoid fever, contracted at the same time as the fatal seizure of Professor Munro of Cambridge.

A third case was observed in a tubercular lad who was under my care at the Seamen's Hospital in 1877. He was admitted suffering from severe debility and prostration, complaining of pain in all his limbs, and especially across the loins, and some coarse râles were heard in the bronchial tubes. The urine was clear, acid, and abundant, averaging about six pints daily, with an average specific gravity of 1016, urea was in excess, and the phosphoric acid excreted amounted on more than one occasion to over nine grammes in the twenty-four hours; whilst the average of several observations gave nearly seven grammes. Previously to the commencement of the illness, about three weeks before admission, he had always enjoyed good health. During the attack he had lost 18lb. in weight. After being kept a week in bed the râles in the chest cleared up, and he was not so prostrate, but several boils made their appearance. He regained a greater portion of his lost weight whilst in hospital, and the urinary secretion was diminished from an average of six pints to barely four, and the phosphoric acid from 9·6 to 4·8 grm. *(To be concluded.)*

A CASE OF

PARTIAL ENTEROCELE (IRREDUCIBLE) ASSOCIATED WITH DOUBLE HERNIAL SAC; OPERATION.



BY WILLIAM HENRY BATTLE, F.R.C.S.,
RESIDENT ASSISTANT-SURGEON TO ST. THOMAS'S HOSPITAL.

IT is now nearly two years since the patient whose case is related below came under observation, and during that time I have been unable to find any record of a similar condition. A good deal of attention has been drawn to the rarer forms of femoral hernia by the discussions which have taken place at the various Medical Societies during the last few months, and I hope that the publication of this case will elicit information with regard to others resembling it.

Mrs. D——, aged forty-five, married, and the mother of several children, was sent to me from the country on Monday, March 17th, 1884, for irreducible hernia. She had had a hernia in the right groin for five or six years, and had worn a truss, the hernia being always reducible until lately; she could not state the exact time that it had been irreducible. Pain was first felt in the swelling on March 10th, but as this was slight she did not send for her medical attendant until the 14th, when there was much more pain, the swelling was larger, and she felt anxious about it. There had been no vomiting, and the bowels had acted naturally. Ice was applied and the diet restricted, but there was no improvement.

When she came under my care there was a femoral hernia on the right side the size of a large duck's egg, fluctuating, but without any particular pain or tenderness. There was impulse on coughing, which was probably conveyed from the abdominal wall. It was dull on percussion, and extended outwards to within two inches from the anterior superior spine. There was no abdominal distension, and no vomiting. The bowels had acted three days before. The tongue was slightly furred. The pulse was quiet and the temperature normal. There was no albuminuria, and the internal organs appeared healthy. Ice was applied and the legs flexed over a pillow, milk only being given.

On the 21st there had been no improvement, the swelling had not diminished, and the patient was anxious to have some-

Vertical antero-posterior section.

thing done for her relief. Accordingly, with the assistance of Mr. Edmunds and Mr. Tyrrell (who administered ether), an incision was made, about two inches long, over the sac and rather to its inner side, the dissection carried down to the sac and then opened on a director, when there was an escape of from three to four ounces of yellowish fluid, which soon coagulated after removal from the body. A small projection about the size of a filbert was then seen occupying the position of the femoral ring, the surface of which was dull-purplish in colour, smooth, but slightly irregular, and quite adherent all round. It did not appear to be intestine. Careful incision proved this to be a thin, tough, fibrous membrane, which was separated by a layer of fluid from a small projection of the intestinal wall, which was firmly adherent to the crural canal all round and irreducible, purplish in colour, in a good state of vitality, but with less than the usual clearness of polish. As this was evidently not strangulated, and there appeared considerable danger of tearing it by any attempt to separate the strong adhesions, it was left *in situ*. The membrane was removed with scissors, the sac wall dissected up, excess cut off, and the remainder closed over the adherent intestine by means of catgut sutures. Two split drainage-tubes were employed, one being placed under the new sac and the other in the space left after the dissection of the old one; these were brought out below and the wound closed with catgut and silk sutures. No vessel required ligature. The carbolic spray was used when the sac was opened, and full antiseptic dressing employed. The patient was rather faint towards the close of the operation, but soon recovered.

The after-progress of the case was satisfactory and

Digitized by Google

recovery uninterrupted. The wound was dressed twice, the inner tube being removed at the first dressing on the evening of the following day, and the outer with the sutures at the second dressing a few days later. A pad and bandage were then applied for a time. The patient was not advised to wear a truss, and left my care on April 6th.

The rough diagram on the preceding page will probably assist in understanding the condition of the parts as found at the operation.

We have here three conditions which in my opinion deserve special comment, and are each of great rarity: (1) The partial enterocele; (2) the membrane which by its position divided the sac of the hernia into two parts; and (3) the distension of these sacs by fluid.

Before the operation my diagnosis was, distension of the hernial sac by fluid, secondary to the blocking of the canal by a piece of omentum. The complete absence of symptoms in connexion with the intestinal tract made it unlikely that there was intestine present, and the absence of resonance on percussion pointed in the same direction. At the operation the condition described above was revealed, and from the small amount of the intestinal protrusion, and its firm adhesion without the causation of any symptom, there can be no doubt but that it was a partial or lateral enterocele, or, as some have preferred to call it, Richter's hernia.

It is difficult to account for the presence of a membrane of such perfect formation in the interior of the sac of a hernia; tough, fibrous, and inelastic, it did not give the impression that it was of recent date, and this makes the explanation of the pathology of the case less easy. It has appeared to me that possibly its origin was due, in the first place, to a limited but complete inflammatory adhesion of the neck of the sac just external to the canal, following irritation produced by the pressure of a truss, subsequent stretching of this adhesion by internal and external pressure, the former caused by the frequent attempts of the gut to descend the canal, and that from without by the pressure of the truss aided by the presence of fluid in the old hernial sac. There was, however, no evidence of this, and the membrane, which was of the thickness of writing-paper, did not appear to slope away at its insertion, but was as distinct as the attachment of the parchment of a drum, and was smoothly lined on both surfaces. By the presence of this membrane, whatever may be the explanation of its origin, and by the adhesion of the intestine to the crural canal, two sacs were formed, each of them being in a condition for the production of what is known as hydrocele of the hernial sac—a condition so rare that Mr. Langton, in his remarks on a case,[1] stated that he had only found a record of the one case which he was describing out of almost 7000 cases of femoral hernia recorded by the Truss Society during a period of eighteen years. The fluid in these sacs was probably much of it the result of recent irritation, but there was no evidence of actual inflammation at the time of operation.

PYREXIA AND HYPERPYREXIA.

BY T. J. MACLAGAN, M.D., M.R.C.P.,
PHYSICIAN IN ORDINARY TO THEIR ROYAL HIGHNESSES PRINCE AND PRINCESS CHRISTIAN OF SCHLESWIG HOLSTEIN.

THE physiological facts which have to be kept before us in considering the theory of fever are as follows:—1. Two main processes are constantly going on in the system—tissue formation and tissue disintegration. 2. During tissue disintegration there are formed various products destined for elimination; the chief of these are urea, carbonic acid, and heat. 3. Urea is eliminated by the kidneys, carbonic acid by the lungs, and heat by the skin. 4. In the case of each, production and elimination are so well balanced that no accumulation takes place in the system. 5. In the case of heat this balance is so well maintained that the normal temperature is always the same (98·4° F.).

In fever the whole process is disturbed; there is increased formation of urea and carbonic acid, and the temperature rises above 98·4°. This rise of temperature is regarded as the pathognomonic feature of the febrile state, and its extent as the index to the amount of febrile disturbance. All theories of fever essentially consist in an attempt to account for this rise. The readiest and most natural way of doing so is to attribute it to increased activity of the processes which keep up the normal temperature. We accordingly find that the most generally accepted of the modern theories of fever—the so-called combustion theory—is that which attributes it to such increase. "Fever," says Virchow, "essentially consists in elevation of temperature, which must arise from an increased consumption of tissue." Liebermeister defines it "as a symptom-group, at the foundation of which is an elevation of the temperature of the body produced by a morbid general increase of metamorphosis."

The evidence of increased tissue metamorphosis in fever is the wasting of the tissues, and the increased elimination of urea and other excretory compounds. This distinct evidence of increased tissue metamorphosis, and the undoubted competence of this to cause a rise of temperature, are the foundations on which this theory of fever rests. If this expressed the whole truth, and if fever simply consisted in increased heat due to increased tissue metamorphosis, the amount of febrile disturbance ought to bear a direct relation to the extent of the tissue disintegration, and the quantity of excreta eliminated would be directly as the amount of fever. The fact that such is not always the case, and that the amount of urea excreted does not always rise and fall with the rise and fall of the temperature, has cast doubts on the accuracy of this theory, and led observers to seek for some other explanation of the rise of temperature. The combustion theory is not discarded, but it is regarded as inadequate to explain all the phenomena which present themselves in fever; and the more one studies these phenomena at the bedside, the more apparent does it become that increased tissue metabolism is not enough to explain them all.

In 1863 Traube advanced the hypothesis that the rise of temperature was due to retention of heat consequent on contraction of the minute arteries. Liebermeister and Leyden demonstrated the inaccuracy of Traube's hypothesis, and by a series of careful observations showed that the febrile body does give off more heat than the non-febrile—a fact already made familiar to every clinical observer by the greater sense of heat felt by the hand placed under the bedclothes of a patient suffering from fever, as compared with that felt in the case of the non-febrile. Ten years later Senator revived Traube's hypothesis in a modified form. He supposed that there are periodic diminutions of loss of heat, together with a constant, though not great, increase of heat production. But this is mere hypothesis, and is opposed to the facts observed by Liebermeister and Leyden.

It seems to me that there is really no valid reason for supposing that during fever the mutual relation of heat-production and heat-elimination is materially altered. That there is increased production of heat is undoubted; but a careful consideration of the facts with which we have to deal shows that increased production is met by increased elimination. The range of the temperature in fever has its limits, just as that of health has; the range is wider and more variable, it is true, but still it has its recognised limits. It could not be so limited were the increased production of heat which causes the rise not met by increased elimination. In health an adult produces in half an hour heat enough to raise the temperature of his body 1°C. Were heat to go on being formed uninterruptedly at this rate, without any elimination, the body would rapidly become very hot, and would reach the boiling point in thirty-six hours.[1] As it is, the heat does not exceed 98·4°. In fever the amount of heat produced is much greater. Were this increased production to go on with only the normal elimination of health, the range of febrile temperature would have no limits—the temperature would go on rising day by day till it reached a point which was incompatible with the continuance of life. As it is, the temperature in fever rarely reaches 106° F., and the immense majority of fever patients recover. In typhus fever the maximum temperature is reached by the fifth or sixth day, but the fever goes on for a week or ten days more, all the symptoms increasing in severity; but in very few cases is a higher temperature noted during the second week than was observed before the completion of the first, and yet all that time there is marked wasting of the nitrogenous tissues and increased elimination of urea. The fever process, with its increased metamorphosis and increased heat production, con-

[1] Landois' Physiology, p. 445.

Digitized by Google

tinues in full swing, but the temperature does not rise—clearly showing that there is no accumulation of heat, and that increased production is met by increased elimination. In typhoid fever the same thing is observed. By the tenth day, or even earlier, the temperature generally reaches a height which is not exceeded during the remaining course of the fever, and an attack of typhoid may go on for three, four, or five weeks without having a higher temperature than was noted at the end of the first: clear evidence that the increased formation of heat, which keeps the temperature up, is counterbalanced by increased elimination. Why is this? Why should the temperature rise rapidly during the first few days and not go on rising? The same cause which made it rise during these days continuing in full operation, why should there not be the same result? The stage of invasion of a febrile attack is that at which the first symptoms of the action of the poison on the system are felt. The earliest indication of this action is a feeling of cold and misery—a desire to hug the fire. The cause of this is contraction of the minute arteries of the skin. The feeling of cold to which this contraction gives rise is a mere subjective sensation; at the time at which it is felt the temperature is really above the normal—may be, several degrees. Besides this subjective sensation, another result of this spasm of the minute arteries of the skin, that which concerns us at present, is decreased elimination of heat. It is by the skin that heat is normally eliminated; contraction of the cuticular arteries, by diminishing the flow of blood to the surface, produces a corresponding and consequent decrease in heat elimination. While the condition of the cuticular vessels thus interferes with the free elimination of heat, the fever-producing cause is at work in the system, causing heat to be produced there in more than normal amount. The inevitable result is the undue accumulation of heat in the system and a rise of temperature.

This is what takes place during the early days of a febrile attack. In the course of a few days the spasm of the minute arteries passes off, the blood again flows freely through them, the heat-eliminating function of the skin is thus restored, and keeping pace with heat production, prevents a further rise of temperature. Thus is to be explained the fact that in typhus fever the temperature reaches its maximum by the fifth or sixth day, rising little, if at all, after that time. It rises up to that point because there is increased formation of heat, and because the condition of the skin renders impossible a corresponding increase in elimination; it ceases to rise after that time, when the blood again circulates freely through the skin—not because the fever-producing cause has ceased to act, but because the mutual and normally counterbalancing relations of production and elimination are restored, and increased production is met by increased elimination. When the fever comes to an end, and heat production returns to the standard of health, there is still in the system a more than natural amount of the excretory products formed during the last days of its continuance—the chief of these are urea and heat; we consequently find that the phenomena of defervescence essentially consist in increased action of the kidneys and skin, the former evidenced by the loaded condition of the urine, the latter by the perspiring skin and rapidly falling temperature. Taking this view of the nature of heat—regarding it as an excretory product requiring to be eliminated,—it is evident that increased formation of heat must give rise to increased elimination so long as the skin can perform its functions. Increased formation of any excretory product leads to stimulation and increased activity of the organ by which it is eliminated. Urea is the natural stimulant to the kidneys, and its injection into the circulation gives rise to increased activity of these organs and an increased flow of urine. Carbonic acid excites the respiratory centre, and its increase in the blood causes increased activity of respiration. In the same way increased formation of heat gives rise to increased activity of the heat-eliminating function of the skin; hence it is that before an attack of fever has lasted many days increased formation of heat is balanced by increased elimination, and no further rise takes place, though the fever process continues unabated.

Such are the facts. During the continuance of the febrile process there is increased tissue disintegration and consequent increased formation and elimination of the products of such disintegration. The chief of these are urea, carbonic acid, and heat. The so-called combustion theory is simply an exposition of these facts. It is not a theory of fever in the sense of being an explanation of the mode of production of the febrile state; it is merely an attempt to explain one of the phenomena of that state—increased body heat. But a theory of fever to be satisfactory must not only tell us what are the essential phenomena of the febrile process; it must tell us also how the process is originated. If the first step in the production of fever be increased tissue-change, the first requisite to a satisfactory theory of fever is that it should account for this change; this the combustion theory as hitherto expounded fails to do; it gives a reasonable explanation of the leading phenomenon of fever—rise of temperature; but offers no explanation of what, according to this theory, is the cause of this rise, and therefore a prior step in the production of fever—increased tissue change. We accept the combustion as a fact, but in accepting it we ask for an explanation of its occurrence. We see that the fire is burning, and we recognise the results of the combustion; but we want to know how it originated, and who applied the match that set it a-going? This manifest shortcoming of the combustion theory did not escape the observation of even those who are its chief exponents. To his definition of fever, that it "consists essentially in elevation of temperature, which must arise from an increased consumption of tissue," Virchow adds the rider that this increased consumption "appears to have its immediate cause in alterations of the nervous system." But whence these alterations, and what are they?

It has been suggested by Dr. Ord[1] that the rise of temperature in fever may be partly due "to the persistence in the form of heat of energy which should have taken another form." In fever, tissue-formation is practically in abeyance, and his suggestion is that, as in health the process of tissue building uses up heat, its cessation leads to the liberation of heat enough to raise the temperature of the body. But does the process of tissue-building use up heat and its cessation liberate it? In support of his assumption that it does so Dr. Ord adduces no evidence, and frankly admits that there is none. That a small amount of heat may be absorbed during the formation of some of the intermediary products of tissue metabolism is generally admitted, but the question raised by Dr. Ord is not whether or not heat may be absorbed during the formation of these products, but whether or not it is absorbed during tissue formation—a totally different question. It is contrary to all physiological law to assume that a product of retrograde tissue metamorphosis, an excretory product, as heat undoubtedly is, should be freely used in tissue formation. The position is essentially and physiologically unsound; and Dr. Ord's suggestion that by the cessation of the processes of tissue formation heat is "left to run wild" cannot but be regarded as an exaggerated and inaccurate estimate of anything that can possibly take place in the way of heat liberation. His observations on the relative temperatures of growing and ripe cucumbers are beside the mark. We are dealing with animal heat, and even in this the question for consideration is not so much whether heat may be absorbed, but *whether during tissue formation it is absorbed in quantity sufficient to lower the temperature of the whole body several degrees.* If there is not absorbed during tissue formation enough heat to lower the temperature several degrees, there cannot, when tissue formation ceases, be liberated enough to raise it several degrees. But even the acceptance of Dr. Ord's hypothesis would not materially better our position so far as our knowledge of the causation of fever is concerned. "Rise of temperature," says Dr. Ord, "results partly from the cessation of tissue formation." But why does tissue formation cease? Dr. Ord's hypothesis is based on an unsound physiological assumption. There is no good reason to regard heat as other than essentially excretory in nature; and the more we keep this physiological fact before us in investigating the phenomena of the febrile state, the less liable shall we be to fall into error, and the more likely to interpret aright the complex and varied phenomena which go to constitute that state. Dr. Ord's hypothesis, though it cannot be accepted as tenable, or as affording any relief to the difficulties by which we are beset, is an expression of the existence of these difficulties, and of the fact that there is much in the phenomena of the febrile state which the combustion theory does not suffice to explain. It is a call for more light.

It is since the combustion theory of fever was pro-

[1] Brit. Med. Journal, vol. ii., 1885.

Digitized by Google

pounded that the thermometer has come into general use as a means of clinical research. By its aid we have not only acquired a more accurate knowledge of the range of temperature in ordinary febrile and inflammatory ailments, but have also gained much information regarding the clinical history of other morbid conditions. Among the most important of the results which have accrued from its use is the recognition of the condition to which the term hyperpyrexia has been applied. In ordinary fevers and inflammations the temperature rarely reaches 106°, and 105° is looked upon as very high. Hyperpyrexia essentially consists (1) in a temperature which runs up, generally very quickly, to 107°, 108°, 109°, 110°, or even higher; and (2) in the coincident development of alarming nervous symptoms, usually resulting in death by coma. Hyperpyrexia is not a disease *per se*, but an incident occurring in the course of other ailments. The recognition of this condition, of the circumstances under which it arises, and of the phenomena which go to constitute it, has probably done more than anything else to shake confidence in the combustion theory of fever; and no wonder, for it is apparent that, while that theory of fever may afford a fairly adequate explanation of the rise of temperature which occurs in ordinary pyrexia, it is quite incapable of explaining the condition which has to be dealt with in hyperpyrexia. The rapidity with which the temperature attains such a height, the absence of the other evidences of such increased tissue disintegration as should from this view accompany so great a rise, and the fact that hyperpyrexia rarely occurs in those fevers in which the evidence of increased tissue disintegration is most pronounced, show that the combustion theory of pyrexia does not suffice to explain the phenomena of hyperpyrexia. Pyrexia and hyperpyrexia have been linked together clinically and pathologically, and looked upon as different degrees of the same condition, allied both in nature and causation. The inadequacy of the combustion theory to explain the occurrence of hyperpyrexia has thus materially weakened its foundations as a theory of pyrexia, and the necessity for finding some other explanation of the very high temperature of the former has led to the enunciation of new views as to the causation of the more ordinary temperature of the latter.

But it is by no means certain that we are right in thus linking these two conditions so closely together, and in looking for one common explanation of both. Their clinical histories are so distinct, and the circumstances under which each occurs so different, that we are scarcely warranted, without some very special reason for doing so, in assuming similarity of causation. No such special reason exists. The only bond between them is the occurrence in each of a higher than normal temperature; but our knowledge of the mode of production of febrile temperatures is not such as to warrant us in saying that there is only one way in which a rise can be produced, that all rises of temperature are due to one cause, and that pyrexia and hyperpyrexia are due to the operation of this cause acting in different degrees. Were this the case—were hyperpyrexia merely an exaggeration of pyrexia, and produced by the same agency,—we should find pyrexia running into hyperpyrexia much more frequently than it does, and hyperpyrexia would be most common in ailments in which pyrexia is most pronounced and most a source of danger. Typhus, typhoid fever, relapsing fever, cerebro-spinal fever, scarlet fever, measles, pneumonia, peritonitis—those diseases, in short, in which pyrexia is most pronounced, prominent, and prolonged—are the ones in which hyperpyrexia would most commonly occur were this view of its nature the correct one. But it is rarely met with in these maladies, and when it does occur is regarded as not only a rare but an accidental complication. The physician finds hyperpyrexia occur, not in connexion with the continued fevers or severe inflammations, but in cerebral hæmorrhage, in heat apoplexy, and in those cases of acute rheumatism which are accompanied by cerebral symptoms—what used to be called cerebral rheumatism. The surgeon finds it not in long-continued or severe inflammations of wounds, bones, veins, &c., but in certain injuries of the cervical cord involving little or no inflammatory disturbance. One point in the clinical history of hyperpyrexia is specially prominent—the association with the very high temperature of prominent nervous symptoms. This association is all but invariable, and such symptoms are as essential a part of the morbid condition to which we apply the term hyperpyrexia as is the very high temperature to which it owes its name.

The question at once arises, What is the mutual relation of the high temperature and the cerebral disturbance? There are two views on this point: one, that the high temperature is primary and the nervous symptoms secondary; the other, that the nervous disturbance is primary, and the high temperature a consequence of it. According to the former, the high temperature of the blood causes disturbance and ultimately paralysis of the nervous centres.[3] But were this the sequence of events, the prominence of the nervous symptoms would be directly as the height of the temperature, and such symptoms would be most marked in ailments in which the temperature runs highest; but such is not the case. Isolated cases of disease are on record in which very high temperatures have been noted without coincident nervous symptoms; but, leaving out of account these rare and exceptional cases, we need only turn to the clinical history of relapsing fever for decided evidence that high temperatures do not necessarily produce serious disturbance of the nervous centres. In that fever it is not an uncommon thing for the temperature to run up to 106°, 107°, or even 108°, without the occurrence of any symptom other than this high temperature to distinguish cases in which it occurs from cases in which the temperature never exceeds 103° or 104°. "A circumstance of some importance in the pathology of pyrexia is the fact conclusively established by many independent observers that these high temperatures in relapsing fever entail little or no danger to the patient, and do not produce serious cerebral symptoms" (Murchison). Did a high temperature of the blood have on the nervous centres the disturbing influence attributed to it by Liebermeister and others, head symptoms would be a prominent feature in these cases of relapsing fever with high temperature. But such is not the case; for head symptoms are much less prominent in them than in typhus and typhoid fevers, in which the body heat is several degrees lower.

HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

GUY'S HOSPITAL.

SEVEN CONSECUTIVE CASES OF CHARBON TREATED SUCCESSFULLY BY EXCISION (*continued*).

(Under the care of Mr. BRYANT.)

IN the last issue of THE LANCET (pp. 367–8) we published cases which form the commencement of the series which is here continued. The period which had elapsed from the apparent beginning of the disease until the patient came under care varied from one to six days, and the efficacy of the treatment by excision is again confirmed by the marked improvement which immediately followed its adoption, and the ultimate good result in each case.

CASE 3. *Charbon of neck with great œdema and lymphatic enlargement; excision, followed by severe pyrexia; cure.* (From notes by Messrs. Beard and J. W. Roberts.)—J. M——, aged fifty, a waterside labourer (and he occasionally has to handle foreign hides), was admitted on Oct. 31st. Family history good. On the previous Tuesday (Oct. 27th) the patient felt a pimple situated about the angle of the jaw on the left side. The swelling increased very much in size on the Friday and Saturday following. He does not remember having scratched or cut himself. He had the same clothes on the day that he noticed the pimple as he was wearing a month previously, and then he had been handling some hides from foreign parts.

On admission the patient looked a strong healthy man. There was a swelling on the left side of his face about the angle of the jaw; it presented a dark central spot surrounded by a circle of vesicles, and beyond this the

[3] Liebermeister: Deutsch. Arch. für Klin. Med., vol. i., 1856.

Digitized by Google

swelling was red and œdematous. Mr. Targett found abundant bacilli anthracis in the discharge.

Oct. 31st.—Mr. Bryant at 3 o'clock this afternoon removed the pustule and a good deal of the surrounding structures; one artery had to be twisted. The wound was afterwards washed with carbolic acid, 1 in 1, dressed with dry gauze, and a sponge placed over it. Evening temperature 104°.

Nov. 1st.—Ordered five grains of sulphate of quinine every four hours until the temperature falls; to have milk and ice, and four ounces of brandy. The patient to be sponged if his temperature goes up to 104°. Ten grains of colocynth and hyoscyamus to be given at once, also fifteen grains of antipyrin, to be repeated in four hours if necessary.

2nd.—12.30: Ordered eight minims of kinate of quinine (solution of kinate of quinine, one grain in four minims). *3.45*: Injection of eight minims of kinate of quinine. The patient has had ice applied to his head; his bowels are open.

8th.—Ordered compound acid mixture.

9th.—Patient got up in the evening for the first time; he felt rather weak. Temperature normal. There is a slough at the bottom part of the wound; the upper part looks very well. There is still œdema below the wound.

Dec. 3rd.—The skin below the wound became undermined, and a large slough formed. This has been coming away in small pieces with the discharge for the last three weeks; it has now nearly all gone, and the wound looks quite healthy.

5th.—The slough has now gone, and there is only a slight discharge from the wound. The inflammation around the wound has subsided.

CASE 4. *Charbon on right cheek, with œdema of neck; excision; application of pure carbolic acid; cure.* (From notes by Messrs. Elliott and H. P. Ainsworth.)—W. H——, aged fifty-one, a skin porter, was admitted on Jan. 21st. The patient carries hides; these are from China, Australia, Bombay, the Cape, &c. On January 16th he noticed a stiffness and tightness of the skin on his right cheek; on the 17th this was more apparent, and on the 18th a vesicle formed. On the 19th this burst and some watery fluid came away. There was but little pain in the cheek. The patient kept at work until the 20th. Poultices had been applied to his cheek.

On admission the temperature was 99°. The patient has not been sick. On his right cheek, about one inch in front of the lobule of the ear, is a circular patch three-quarters of an inch in diameter. There is a small black eschar in the centre of the patch about the size of a pea; around this, especially at the anterior and lower parts, is a zone of vesicles, becoming confluent; around this, again, is a zone of redness, which gradually fades off into the surrounding parts, which are œdematous. The œdema extends forwards to the angle of the mouth and backwards and downwards into the neck. An enlarged gland can be felt below the body of the jaw.

Jan. 21st.—Chloroform was administered; Mr. Bryant cut out the skin and subcutaneous tissue around, including the eschar, by an incision about one inch in diameter and three quarters of an inch in front of the lobule of the ear; there was very little bleeding and only one vessel was twisted. Pure carbolic acid was applied to the raw surface, and the wound was then dressed with iodoform strips and gauze. Several attempts were made to find bacilli in the serum exuding from the vesicles, but none could be found; at last, however, three were found in one slide, but they were not certainly anthrax.

22nd.—There was but little bleeding; the wound was dressed to-day and looks clean and well. Patient is not in much pain. He was ordered quinine and iron mixture with infusion of calumba three times a day.

26th.—The small gland near the angle of the jaw has increased in size and become very hard; the skin over it is tense. Evening temperature 100°, the highest recorded.

31st.—The discharge from the wound is very slight; the enlarged gland is slowly decreasing in size.

Feb. 8th.—The wound is circular, about the size of a penny, and the granulations are small, healthy, and level with the surface. The enlarged gland is still firm and hard, but seems to be decreasing.

12th.—The wound is now about the size of a halfpenny, the redness around the wound is fading away, and the enlarged gland is much smaller and softer.

16th.—The patient went to a convalescent home to-day. The wound is about the size of a sixpence, and covered with healthy granulations; the gland behind the jaw is smaller, and soft.

CASE 5. *Charbon on the left side of the neck; excision; application of carbolic acid; cure.* (From notes by Messrs. Taylor and Coombe.)—J. B——, aged thirty-two, a skin-dresser, was admitted on April 14th, 1886. On April 5th the patient felt a pain on the left side of his neck. This pain seemed to pass down his neck. He thought it was only a stiff neck. On the 8th he noticed a small pimple in the region of the pain; the pimple was about the size of a pin's head, and was painful. The following three days the pimple increased in size, and became more painful. On the 12th he saw a doctor, who treated him for carbuncle, and ordered poultices to be applied. He got no relief from the poultices. On the 13th he went to work, but was obliged to leave off. When he woke on the 14th he was unable to raise his head, and had great pain in his neck.

The patient is a strong, healthy-looking man. On the left side of the neck, at the posterior margin of the sterno-mastoid, and about two and a half inches below and behind the lobule of the ear there is a swelling about the size of a florin, slightly raised above the surrounding skin. There is a black spot in the centre surrounded by a zone of redness, outside of which, entirely surrounding it, is a complete circle of vesicles containing clear serum; the tissues around are all swollen, and have a red brawny appearance; the swelling extends some three or four inches around. Shortly after admission chloroform was administered, and a circular incision was made round the swelling, and the whole removed. There was not much bleeding. Pure carbolic acid was applied.

April 15th.—The patient seems much relieved since the operation. Ordered sulphate of quinine (three grains), with dilute sulphuric acid and infusion of gentian, three times a day.

16th.—The patient slept better last night, and says he feels better.

27th.—The patient now gets up every day, and has gone out of doors for a short time. Wound looking well; granulation healthy.

May 8th.—The patient is not so well this morning; complains of headache, and has occasional shivers; he is thirsty. Temperature 100°. There is a little redness to be seen round the wound, but its extent is very small. To keep in bed.

CASE 6. *Charbon on the right cheek, with lympathic enlargement; excision, and actual cautery.* (From notes by Messrs. Metzgar and Meares.)—W. D——, aged fifty-four, a labourer in a hide warehouse, was admitted on June 10th. On the 9th he noticed a small lump on the right cheek, about an inch above, and external to, the corner of the mouth; it was hard, and had a bright-red spot at the apex; it was not painful, but irritating. On examination of the cheek, there was seen a small elevated papule; it consisted of a small, dark-coloured central spot, surrounded by a ring of vesicles secreting a clear serous fluid, outside which was an area gradually running down to the surrounding skin levels, and outside this again a third circle, which showed a reddish, bluish colour, gradually fading out into the surrounding tissues. The patient was put under chloroform at once, and the papule dissected out, and removed between two circular incisions. There was slight bleeding from a small artery. The actual cautery was applied to the wounds.

June 12th.—The patient feels weak and sick; his submaxillary glands, especially on the right side, are enlarged. Temperature 99·6°. Urine clear, and light in colour; reaction acid; sp. gr. 1008; no albumen, sugar, blood, or pus.

13th.—Temperature 99°. Patient is sick and weak, glandular swelling less. A sixth of a grain of morphia was given subcutaneously, and aperients ordered.

14th.—Temperature 99·6°. Patients says he feels weaker and not so comfortable. Bowels very confined; no action since admission.

15th.—Bowels opened last night and again this morning. Temperature 100°. Glands smaller. Patient's appetite poor. He is in pain if he moves his jaw. There is a strong history of gout. He has gout in the right knee and foot; ankle a little swollen and inflamed; knee is not swollen. A mixture containing vinum colchici and alkalies ordered.

17th.—Knee painful. Temperature 99·6°.

25th.—Wound healthy; granulating freely.

July 1st.—Patient got up for an hour or two yesterday.

CASE 7. *Charbon of face, with surrounding œdema; excision; cure.* (From notes by Messrs. W. F. Clarke and W. C. Swayne.)—F. T——, aged twenty-three, a worker in a dye-house of a leather merchant, was admitted on Dec. 23rd, 1886. On Dec. 20th a small pimple came at the root of the nose. On the 21st, whilst at work among leather, he picked the top off the pimple, and he says a hard morsel like a crystal of brown sugar came away (possibly hardened serous effusion); after this his eyes began to ache, and were swollen under the lower lids. On the 22nd the pimple became more painful, and the swelling under the eyelids increased.

There is a small sore at the root of the nose in the median line, about the size of an ordinary shirt-button in circumference, and for a small area around the part affected it is indurated and swollen. Underneath the eyes it is much puffed, and the parts are very painful. No enlarged glands. No vesicles to be seen around the sore. Some of the fluid from the sore was examined, but no bacteria could be found. Urine acid; sp. gr. 1015; no albumen or blood. Temperature 99·4°.

After admission, chloroform having been administered, a circular incision three-fourths of an inch in diameter was made round the sore, and the whole of the tissues excised down to the bone. Very little bleeding occurred. The wound was washed with iodine lotion, and iodine dressings applied.

Dec. 25th.—Wound looking well; no pain. The swelling under the eyelids is almost gone. Temperature normal.

29th.—The patient gets up and remains about the ward all day. No sign of inflammation around the part. The œdema of the face has entirely disappeared.

Jan. 4th, 1887.—The patient has been going on very well. Wound looking healthy and filling up; but at 7 o'clock this morning he had a rigor, and was put to bed, with hot-water bottles to his feet. 11 A.M.: Still has a fit of shivering come over him now and then. Temperature 99·2°; skin feels hot and moist.

7th.—Patient discharged well.

DEVON AND EXETER HOSPITAL.

UNILOCULAR OVARIAN CYST IN A GIRL AGED THIRTEEN; OVARIOTOMY; REMARKS.

(Under the care of Mr. BELL.)

FOR the notes of the following case we are indebted to Dr. A. Blomfield.

Edith G—— was admitted on Aug. 19th, 1886, with a fluctuating abdominal tumour. The girl was very small and undeveloped for her age, and had never menstruated. About four months before her admission she complained of pain in the left iliac fossa, which she describes as "like stomach-ache." The pain was afterwards felt higher up and on the opposite side of the abdomen. She is certain that there was no enlargement at this time, but that shortly afterwards the abdomen began to enlarge and increased somewhat rapidly to its present size. There has been no jaundice, vomiting, or œdema of the legs.

State on admission.—The abdomen is much enlarged, presenting a somewhat barrel-shape appearance. The superficial veins are not prominent, nor is there any œdema of the walls. The circumference of the abdomen, one inch above the umbilicus, is thirty-two inches; the left side measuring three-quarters of an inch more than the right, and the measurement from the left anterior superior iliac spine to the lower border of the sternum is half an inch more than from the opposite spine. There is complete dulness over the part of the abdomen to the level of the lower border of the sternum; the left flank is quite resonant, the right somewhat less so. There is resonance over the left iliac region, but the right fossa is absolutely dull. There is a distinct free wave of fluid from side to side through the swelling. On placing the hand on the abdomen, a sensation of crepitus can sometimes be felt.

The case was sent into the hospital as probably ascites, but from the examination it was evident that the fluid was encysted, and the opinion given was that the case was one of ovarian dropsy.

On Aug. 28th, under chloroform, Mr. Bell, through a small incision (three inches), removed a unilocular ovarian cyst. The cyst weighed twelve pounds, and contained eight pints and a half of fluid. The pedicle was broad, and sprang from the right side; it was tied in two parts with thick silk, and returned. There was one long thin omental adhesion, which was easily separated. The intestines did not come into view. The left ovary appeared healthy. The abdominal wound was brought together by silk sutures, which were removed at the end of the week, when the wound was found healed. Gamgee tissue was used as a dressing. The girl made an uninterruptedly good recovery.

Remarks by Mr. BELL.—The points of interest in the case seem to be the age of the girl, her small size for her age, the size of the cyst, and its somewhat rapid growth.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Rupture of the Urinary Bladder.

AN ordinary meeting of this Society took place on Tuesday last, Dr. J. W. Ogle, F.R.C.P., Vice-President, in the chair.

Mr. HENRY MORRIS read a case in which the Urinary Bladder was twice Ruptured, the first time by an injury, the second time—seven years after the first—by the giving way of the cicatrix. A man aged thirty-six, had been drinking at a public-house on the evening of June 4th, 1879, when a struggle ensued, and his opponent threw him and knelt with violence upon his abdomen. All the symptoms of peritonitis and rupture of the bladder were excited, and the patient was admitted into the Middlesex Hospital on June 6th, 1879. The treatment consisted of hot fomentations to the abdomen, half a grain of opium in a pill every six hours, and the retention just within the neck of the bladder of a gum-elastic catheter. He recovered perfectly, and left the hospital on July 10th, 1879. He applied at the hospital again on August 4th, 1886, and gave the following account:—On August 2nd he had been at a "beanfeast." On the following morning his bowels acted and he passed some urine, but the latter act was attended with some pain. From this time pain increased, and in the evening he was unable to micturate. He vomited frequently, and had had hiccough since the onset of pain, until the afternoon of August 4th, 1886, when a catheter was passed and nearly three ounces of bloody urine were withdrawn. He was then admitted as a case of peritonitis and suppression of urine. On the 5th about one pint of thick, purulent, and slightly blood-stained urine was drawn off. At 7 A.M. on August 6th he passed a little flatus and a large quantity of urine, and suddenly became very sick. Soon afterwards he was quite collapsed; his abdomen became very distended; he never rallied, and died at 11.5 A.M. on the same day. At the necropsy recent general peritonitis was found, and in the pelvis there were fifteen ounces of purulent urine and a quantity of lymph. A band an inch and a quarter long united the fundus of the bladder with the rectum. The vesical end of this band was hollowed out into a slender funnel, and through a rupture in it close to the bladder a string of mucus was projecting. Slight pressure caused purulent urine to ooze from the bladder through the rent into the peritoneal cavity. The rectum, bladder, and penis were removed *en masse*, and were submitted to a committee consisting of Mr. Savory, Mr. Bryant, and Drs. Goodhart and Kingston Fowler, who reported that in their opinion "the specimen exhibits all the features which might be expected at a remote period after a rupture of the bladder." This case, in the first instance, was reported in 1879 as one of recovery from rupture of the bladder. It is now brought before the Royal Medical and Chirurgical Society because in its completed form it affords conclusive proof that an intra-peritoneal rupture of the bladder is not necessarily fatal, but may be recovered from under the simple treatment employed in this case, provided the urine at the time of the rupture is of normal composition. The case is believed to be unique in that it furnishes us with the post-mortem appearances of the bladder some years after recovery from an intra-peritoneal rupture of the coats of that organ.

Mr. W. H. BENNETT read a case of Extra-peritoneal Rupture of the Urinary Bladder, the direct result of aspiration

Digitized by Google

above the pubes, with remarks on some objections to the use of the aspirator as a means of evacuating the bladder, and suggestions for the treatment of certain cases of retention of urine. The author stated that he had always objected to the aspirator as a means of relieving a distended bladder, excepting in a very limited number of cases, as he believes that its use directly tends, in a large number of instances, to rupture of the organ, or oozing of urine by the side of the needle, in consequence of the immediate relief to the vesical tension being insufficiently afforded by the small instrument commonly employed. The question of vesical tension was discussed as having an important bearing on the subject. The case was then described of a man, aged thirty-eight, who came under the author's care on Sept. 19th, 1886, with retention of urine of three days' duration consequent upon a stricture which had existed for fifteen years. The house-surgeon, having failed to pass a catheter, aspirated the bladder above the pubes. Rupture of the organ immediately followed. The abdomen was laid open by the author, and a large quantity of urine escaped from a cavity in the pelvis and hypogastric region. The bladder was subsequently drained through a perineal incision. The patient progressed satisfactorily till November 6th, when an opening formed between the bowel and the peri-vesical cavity, after which he sank. The preparation and a drawing of the parts were shown. Three other instances in which complications happened were referred to. In conclusion, the following propositions were submitted:—1. Aspiration of the bladder for the temporary relief of retention of urine can only be resorted to with absolute safety for cases in which the bladder walls are presumably healthy. 2. The operation is inadmissible in cases of retention consequent on long-standing stricture, the bladder walls being diseased and often rotten; the appropriate treatment in such cases, if the stricture be impassable, being drainage of the bladder through a perineal incision. 3. The aspirator can be used only with some risk in cases of distended bladder where there is reason to suppose that the urine is foul, unless the organ is washed out with an antiseptic solution before the withdrawal of the needle, and even then aspiration is only applicable to certain cases of retention from prostatic obstruction not associated with long-continued previous cystitis or irritable bladder, such cases being properly treated by prostatotomy and perineal drainage. 4. In any case of bladder-distension where there is reason to suspect disease of the coats of the organ, if tapping be performed at all, a large trocar and cannula should be used, and not a small aspirating needle. 5. In the event of aspiration being followed by pain, supra-pubic dulness, and rigidity of more than a temporary character, incision above the pubes should be practised, the bladder being drained through the perineum if the urethral obstruction be still impassable.

Mr. T. BRYANT thought there could be no doubt that Mr. Morris's was a case of repaired rupture of the bladder, in which in the course of seven years an acquired hernia or sacculus had developed. The case also showed the importance of not interfering with an opening that was in process of repair, and thus suggested a practical hint to the surgeon to be careful in dealing with the bladder so as not to reopen a wound that was already healing. Mr. Bennett's paper gave clear evidence to show that there was some danger in aspirating the distended bladder. He did not remember to have written lightly in his text-book of aspirating the bladder for retention of urine. His own experience had taught him that such a method of treatment might be of a serious character. He alluded to two cases:—1. A man, aged thirty, was seen in 1883, with retention from urethral stricture relieved by supra-pubic puncture; afterwards it was found necessary to perform perineal section, but death followed. Evidences of suppurative peritonitis, with a diffuse sloughing abscess, the result of extravasation of urine, were found at the post-mortem examination. 2. This was the case of a man aged seventy-eight; there was retention from an enlarged prostate, which was relieved seven or eight times by supra-pubic puncture. At the necropsy made by Dr. Goodhart six distinct punctures were visible from the bladder surface, and each opening would allow of the escape of urine into the peritoneum. Even with a healthy bladder there was risk in tapping if the viscus were over-distended. There was an analogy between the aspiration of a tight hydatid tumour and that of a full bladder.

Professor HUMPHRY said that Mr. Morris's case showed that healthy urine could enter the peritoneum without necessarily leading to lethal effects. He considered that the specimens showed that a sinus rather than a sacculus had formed as the result of the original accident. He related the case of an elderly man who had retention of urine from enlarged prostate. Aspiration was performed, with the result of extravasation of urine and fatal consequences. Had the surgeon who aspirated been aware of the possible dangers of aspiration, perhaps the patient's life might not have been sacrificed. He endorsed the importance of the facts brought forward by Mr. Bennett.

Mr. RICHARD BARWELL said that in his experience ruptures of the bladder were usually very large, and that any attempt to treat such cases by the expectant method would not usually be attended with satisfactory results. The diagnosis of a case of extensive from a small rupture of the bladder was very difficult, for the signs of peritonitis might be as marked in the latter as in the former. In order to aid in the diagnosis, the catheter need not be pressed so far as to reopen a rupture. The rate of flow of the urine through the catheter might help in the diagnosis; if the flow increased during inspiration and decreased with expiration, the surgeon should not wait, but perform abdominal section, for if such a flow of urine be obtained, a large rupture might reasonably be concluded to exist. He concurred in the views expressed by the previous speakers on Mr. Bennett's paper.

Mr. J. W. HULKE said it was very difficult to obtain clear and decisive evidence of a large vesical rupture. Mr. Morris's case was valuable, as showing that even adverse circumstances were not absolutely hopeless. He had long been convinced of the dangerous practice of aspirating a distended bladder. The mechanism of escape of urine from the bladder he did not feel convinced about; but that was hardly the practical matter. Aspiration was only to be regarded as safe where the bladder and urine were healthy.

Mr. W. RIVINGTON had examined the specimen shown by Mr. Morris, and he considered that a rupture of the bladder had occurred, though he did not agree with the conclusions of the committee who had reported on the specimen. There was no evidence that the bladder had been ruptured by a vertical rent, which would be intra-peritoneal, though this term was not used in the report. Again, there was no evidence of any cicatrix on the mucous or peritoneal surfaces of the viscus, and he did not believe that such evidence would be obliterated in the course of seven years. He would be prepared to admit that there had been a local peritonitis, which would be well explained by a *subperitoneal* rent. He did not think that a true intraperitoneal rupture had occurred. He also considered that there was not much urine in the bladder at the time the original injury was received. Commenting on Sir W. Mac Cormac's cases, he contended that the amount of fluid passed through the abdominal drain was so large that it could not be ascribed to the flow of urine, and must be set down to serum exuded from an irritated peritoneum. Experimental research also showed that normal urine was not innocuous to the peritoneum.

Mr. CHRISTOPHER HEATH said that in the fresh state the bladder showed an undoubted cicatrix, and he fully concurred in the view of Mr. Morris.

Mr. J. K. FOWLER thought there was no doubt whatever of the bladder having been ruptured, and the presence of a distinct though distended and atrophied cicatrix was the evidence of this at the time he made the necropsy.

Mr. HENRY MORRIS, in reply, said that he had merely placed the facts before the members of the Society that they might form their own opinion. He submitted the specimen to a committee of Fellows of the Royal College of Surgeons, so that there should be an unbiased opinion. His case showed at least this—that the continued use of the catheter could be followed by a favourable result, even when there was no doubt clinically of the occurrence of vesical rupture. The infundibuliform adhesion he took to be the actual cicatrix, altered by circumstances in the course of time. The early history of the case, he contended, justified the conclusion that the bladder was distended at the time of rupture.

Mr. W. H. BENNETT, in reply to Mr. Hulke's objections to his explanation of the mechanism of production of the extravasation, said that he believed that a circular opening in the bladder was formed by the aspirator at the time of puncture, but that later on a slough separated from the bladder wall at the site of the vesical puncture.

PATHOLOGICAL SOCIETY OF LONDON.

Shedding of Teeth in Tabes Dorsalis.—Intermuscular Synovial Cysts.—Endothelioma of Dura Mater.—Syphilitic Hyperplastic Laryngitis.—Mitral Aneurysm in a Child.—Ectopia Vesicæ.—Retro-pharyngeal Abscess.—Horny Growth on Penis.

AN ordinary meeting of this Society was held on Tuesday, Feb. 15th, Sir James Paget, Bart., President, in the chair.

Dr. HALE WHITE read a paper on the Falling of Teeth in Locomotor Ataxy, and related the case of a man, aged forty, who had had the first symptoms of locomotor ataxy eight years earlier; ataxy had been present for one year, and the lightning pains for nine months. When admitted taste was impaired, there was anæsthesia in various parts of the body, and girdle pain; all the reflexes were absent, there was loss of sexual power, and some diarrhœa. A wisdom tooth was exhibited which had fallen out two years ago without any previous signs of decay; it was quite healthy. The other teeth were ground down, but otherwise quite healthy. He was treated with iodide of potassium, and went out of the hospital after showing some improvement. Dr. Hale White mentioned some references to this subject. Thus, Richardière (*Rev. de Méd.*, No. 2, 1886, p. 170) related how in a patient suffering from tabes the mouth and face swelled; all the teeth of the upper jaw fell out one by one without any previous caries; after this a few pieces of bone came away from the palate. Hoffman (*Berlin. Klin. Wochen.*, No. 12, 1885) mentioned a case in whom all the teeth fell out of the upper jaw without any apparent cause, and two years after tabes dorsalis showed itself. Dr. Lewis (*Amer. Journ. Nerv. and Mental Dis.*, No. 2, 1885) also gave cases. Dr. Hale White considered that before allowing that this was a definite symptom of tabes dorsalis we should notice many more cases, for the teeth were liable to fall out from so many causes.—Dr. F. SEMON said there were two varieties of shedding of the teeth—one in which the tooth simply drops out, and in the other where part of the alveolus breaks off as well. In cases of gastric and laryngeal crisis such teeth and bone changes should be specially looked for, in view of Dr. Buzzard's theory of the association of the trophic bone centre with the pneumogastric centre.—Mr. BENNETT spoke of an affection of middle life in which from the socket of the teeth a discharge of serum or pus took place, and in some of which cases nodules of tartar developed on the periosteum, and fragments of dead bone came away. It was an absolutely painless affection, the pathology of which was much disputed. Gout and imperfect nutrition were ascribed as causes.—Dr. G. N. PITT referred to two cases of tabes in which a larger number of teeth had been lost than was usual at the age at which the patient had arrived.—Dr. ORMEROD alluded to a case of well-marked tabes in which a part of the alveolus with three teeth had spontaneously broken off. The man had had syphilis. The neurologists considered the fracture due to tabes, but some others—syphilographers—thought the case was due to the syphilis.—Mr. BLAND SUTTON referred to four cases of disease of the spinal cord in animals which had perforating ulcers and nerve troubles. They were carnivora, and all had softening of the alveolus with shedding of teeth, though they were animals who should have had a full supply of teeth.—Sir JAMES PAGET thought it was a subject of much importance, and required further investigation.

Mr. D'ARCY POWER showed some more specimens of Intermuscular Synovial Cysts. After alluding to the examples already brought before the Society in 1885, he said that the present series confirmed in all respects the theories he then advanced. He showed a preparation of a knee-joint from a patient who died of phthisis in St. Bartholomew's Hospital. The joint presented an irregular hourglass-shaped cyst situated over the inner side of the knee, and communicating by a contracted channel with a second enlargement situated in the loose connective tissue of the popliteal space. The bursa beneath the popliteus was also greatly dilated, though not connected with the other swelling. Neither of the cysts communicated with the knee-joint. Mr. Power commenced in an almost bursæ in the neighbourperhaps on some form of then opened one into the line of least resistance. He further pointed out that this was the first case he had dissected in which there was absolutely no communication between the cysts and the synovial cavity of the articulation near which they had formed. In a second specimen in which the joint was extensively diseased, there was a cyst in the same situation as in the first case, but it opened directly into the knee-joint. An especial point of interest consisted in the fact that there was a partially pervious cord connected with the cyst; it represented the remains of a pre-existing cyst, which had been aspirated with antiseptic precautions sixteen months before amputation of the joint. In the third specimen exhibited by Mr. Power the cystic enlargement was due to a hernia of the synovial membrane of the elbow, and not to the distension of any bursa. It was a significant fact that in two of the three cases the cysts occurred in cases associated with tubercular disease of the neighbouring articulation.—Mr. R. J. GODLEE asked for the experience of members of the Society as to the relationship of ganglia on the back of the wrist to tubercular disease of that joint.—Mr. CHARTERS SYMONDS mentioned a case of swelling of solid nature, part of which was composed of caseous material, and referred to a second case of solid growth on the inner surface of the sheath of the tendon of one finger, which proved to be of tubercular structure. He asked Mr. Godlee whether his cases were true ganglia or solid tubercular masses, to which the reply was that reference was made to the sequence of apparent ganglia on the back of the wrist and tubercular disease of that joint.

Dr. HYLA GREVES showed a specimen of Endothelioma of the Dura Mater, removed from a lady aged sixty, who had had attacks of headache localised by tenderness to the right parietal bone. Spasms of epileptiform kind occurred in the left face and hand, sometimes with loss of consciousness, and followed by paresis, but not complete paralysis. Giddiness, vomiting, and double optic neuritis had been noticed. The case lasted fifteen months. The memory was deteriorated. Operative interference was not accepted by the patient or her friends. The tumour was found to have the dura mater adherent over an area the size of a shilling. The external surface of the dura was rough and thickened, and the bone thinned. A branch of the middle meningeal crossed the tumour, which was deeply embedded in, but displaced and depressed, the convolutions about the fissure of Rolando. The tumour had a crenate margin, and was an inch and a half thick. It had a fibrous and greyish aspect, and was blood-stained. A delicate membrane, probably the pia mater, separated it from the brain substance. Cell nests with reticulated strings or bands of cells and a fibrous margin formed the histological structure. The strings or bands were composed of flattened cells arranged in reticulated layers. Many distended blood-vessels were seen, whose walls were composed of flattened cells circularly arranged, and in some places having an ampulla-like appearance, but no separated portions, as described by Cornil and Ranvier in angeiolithic sarcoma. The specimen shown resembled those described by Ziegler as endotheliomata.—Mr. F. S. EVE asked for the precise relations of the tumour to the dura mater, for Dr. Goodhart had presented to the museum of the Royal College of Surgeons a large intracranial tumour growing from and into the bone; the dura mater covered, but was not attached to the growth. He had been surprised to find that the growth was an angeiolithic sarcoma; it consisted of small connective tissue cells, which in places formed whorls, which he thought originated in abortive vascular bands.—Mr. JONATHAN HUTCHINSON thought there was much to be gained by dropping the term "psammoma," and using in its place the term "calcifying endothelioma." The growths differed from sarcoma in their tendency to remain isolated. He recalled a case which he had reported to the Society of calcifying endothelioma, arising in connexion with the vertebral column, which had entirely compressed without invading the cord.—Dr. HYLA GREVES said the dura mater lay external to the growth, and was only attached over a small area.

Dr. F. SEMON showed, for Dr. Jacob of Leeds, photographs and microscopic specimens of Hyperplastic Syphilitic Laryngitis. The patient was a child five months old, who had, from a fortnight after birth, suffered from manifestations of congenital syphilis, and who was admitted into the Leeds Infirmary in November last with cough and huskiness of voice. Laryngeal obstruction soon supervened, tracheotomy had to be performed, and the patient died the same day. At the necropsy no marked change was observed in

Digitized by Google

the upper compartment of the larynx, but below the cords the lumen was reduced to a mere chink by swelling and thickening of the mucous membrane, which extended about three-quarters of an inch downwards, and terminated rather abruptly. The thickening, on section, was of a deep-red colour. Microscopically it was seen to consist of a mucous membrane greatly thickened by interstitial deposit of connective tissue, as well as by hypertrophy of the gland tissue. The vessels were greatly distended. The lungs showed a few patches of lobular pneumonia; the liver an increase of connective tissue, and some small aggregations of leucocytes. Dr. Jacob drew attention to the differences which this case presented from the somewhat similar ones reported by Dr. F. Semon in vol. xxxi. of the Society's Transactions, in that the localisation of the tumefaction was different, and that there was entire absence of ulceration.

Dr. HADDEN showed an Aneurysm of the Mitral Valve removed from a female child, aged two years and three months. There was no history of syphilis or rheumatism. The child became occasionally blue, but no murmur existed. She was taken ill with bronchitis, and suddenly became worse and died. Some blood-stained mucus was found in the larynx, and a caseous mass in the upper part of the right lower lobe. The posterior flap of the mitral valve was the seat of an aneurysm the size of a nut; it measured half an inch in diameter, and bulged into the ventricle. At its auricular orifice there were a few pale firm vegetations; the anterior flap and chordæ tendineæ were healthy. The chief interest was the rarity of the case and its unexplained etiology.—Dr. S. COUPLAND remarked on the rarity, and said, the aortic valves being quite healthy, it was impossible to ascribe the formation of the aneurysm to secondary infection of the mitral valve from the aortic.

Mr. S. G. SHATTOCK showed a specimen of Ectopia Vesicæ from a male child. He said that no adequate explanation had been offered of the occurrence of ectopia vesicæ, which was looked upon as of the same order as ectopia cordis—a deficiency of growth of the mesoblastic basis of the abdominal wall. The explanation submitted by him was that the primitive cloacal invagination of the surface, which normally lays open the lower end of the rectum and the lower end of the urogenital sinus, in these cases, by an undue extension forwards and upwards, lays open the anterior wall of the urogenital sinus and the anterior wall of the bladder. There would thus result a complete fissure of all the parts in the middle line as high as the umbilicus, and the rudimentary penis or clitoris would be on its first appearance completely cleft.—Sir JAMES PAGET remarked on the ingeniousness of the explanation, which he considered to be a highly probable and correct interpretation of the deformity or malformation.

Mr. H. H. CLUTTON read a case of Retro-pharyngeal Abscess that occurred in a man aged twenty-four, who was subject to epileptic fits, during one of which, he asserted, the abscess in the neck formed, or rather, the pain and swelling in the neck were first noticed. But the patient could not give an intelligent account of himself. He had been spitting up a quantity of muco-purulent fluid mixed with blood, which clearly came from the abscess opening into the pharynx. When first seen, the head was retracted, and there was dysphagia, apparently from inability of the larynx to move in the act of deglutition. The larynx appeared to be fixed. There was a rapid subsidence of symptoms. Over the right carotid artery a soft and flaccid area was felt, but it was not thought advisable to incise it. On October 6th, two days after dismissal from the hospital, a sensation of crackling or crepitation could be felt, and the tumour disappeared on pressure. Mr. Semon said the larynx was normal, but there was a small red swelling below the larynx, which was probably a communication with the abscess cavity and the trachea. Nine days after leaving the hospital the patient seemed quite well. On October 23rd he was readmitted with bronchopneumonia, and died on November 3rd. Some retinal hæmorrhages were discovered by Dr. Mackenzie. The patient had albuminuria, but there were no casts in the urine. The left tonsil was in a chronic state of hypertrophy; the right had an abscess which did not communicate with the thin-walled cavity, which reached downwards to the level of the clavicles. The origin of this chronic abscess was uncertain. It opened by three rounded smooth orifices into the pharynx, and by one into the trachea, which, with the larynx, was acutely inflamed. One lung had gangrenous pneumonia. There was no trace of glandular enlargement. He did not know whether the abscess could have originated from a pouch of the œsophagus, but there was no trace of an epithelial lining to the abscess cavity. Reference was made to retro-pharyngeal abscesses of children. — Dr. ERNEST CLARKE remarked on the chronicity of the case. He had had to perform tracheotomy on a child eight months old, who died. The necropsy showed a large post-œsophageal abscess, which, on careful examination, proved to be connected with the third cervical vertebra by a sinus that led into the intervertebral disc.—Mr. M. SHEILD asked whether the abscess could have had its origin in a hæmorrhage in the neck, resulting from straining in an epileptic fit. This blood clot might have become septic and suppurated. Some cases in children might be due to scarlet fever, which had been overlooked.—Dr. ANGEL MONEY remarked that a large majority of the cases occurred in infants a few months old.—Mr. H. H. CLUTTON, in reply, thought the fits were not sufficiently severe to have caused a hæmorrhage into the neck.

Mr. PEARCE GOULD read a case of Epithelioma of the Penis with a horn growing from the glans. The patient, aged fifty-two, had had congenital phimosis, for which he was circumcised only four years ago. The wound healed, except in one place in the middle line, where a small granulation remained. Here a small wart developed, and was followed by a second by its side. The first wart began to discharge, and continued to do so ever since. On the middle of the upper surface of the glans was a sessile truncated horn, hard in consistence, of yellowish colour and translucent, the size of a small marble. The penis was amputated, and large inguinal glands were removed, the patient rapidly recovering. Sections prepared by Mr. L. Hudson showed the usual epidermic structure, the cells being flattened, nucleated, and arranged in regular superposed layers. There were no enlarged papillæ entering the base of the structure. The ulcer was a typical globular epithelioma. The glands showed no secondary deposit. Ninety cases of horns were collected by Erasmus Wilson, of which five were penile. Lebert collected 109 cases, of which six occurred on the penis. A committee of the Royal Academy of Medicine collected seventy-one cases of horns, three penile. This was the fourteenth case. Some of the horns have reached a great size. In Jewett's case the horn was 3½ in. long and ¾ in. in diameter. In Pick's case the horn was 2½ in. long. In Gould's case the corn was regularly pared down. Horns have been shown to start in three different ways: some grow from the interior of sebaceous cysts—the most frequent mode of origin; some develop from the matrix of the nails; and others by some change occurring in warts. Those on the glans penis belong to the last group. Histologically, they may be divided into papillary and flat. The present specimen was of the latter kind.

The following card specimens were shown:—Dr. Hadden: Perforation of Large Intestine in Enteric Fever. Mr. E. H. Fenwick: Renal Carcinoma. Dr. Mott: Myxo-fibroma compressing the Spinal Cord. Mr. Clutton: Congenital Abnormality of Lower Lip associated with Cleft Palate. Dr. Pitt (1) Ulcer of Vagina, possibly tubercular; (2) Two cases of Hydro-salpinx.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Small-pox Hospital Influence.

AT a meeting of this Society, held on Friday, Feb. 18th (the President, Dr. Alfred Hill, medical officer of health for Birmingham, in the chair), Dr. SEPTIMUS GIBBON proposed the following resolution:—"That this Society, having heard that a proposal will be made to the Metropolitan Asylums Board at their next meeting to close the hospital ships and to admit cases of small-pox into the London hospitals, desire to express their hope that the Board will not adopt the proposed motion, which, in their opinion, is not conceived in the interests of the public health."—The motion was seconded by Dr. WOODFORDE, medical officer of health for Berkshire, who said that, as a provincial officer, he was much interested in small-pox, as, whenever an epidemic occurred in the metropolis, it invariably affected his and other districts in the country.—The resolution was adopted, and a copy was ordered to be communicated to the Metropolitan Asylums Board.

Reviews and Notices of Books.

The Healing Art; or, Chapters upon Medicine, Diseases, Remedies, and Physicians—Historical, Biographical, and Descriptive. Two Vols. London: Ward & Downey. 1887.

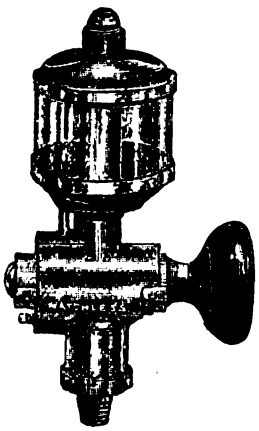
THE history of medicine is a subject which has been strangely neglected in this country, and yet it is one which well repays profound study and investigation. No English author has yet appeared to give us works like those of Haeser and of Hirsch; but such works are the product of a lifetime devoted to literary research, and we have no provision for that in England. There is no University endowment here for the prosecution of these higher studies; but we would fain hope that the day is not far distant when such a defect will be remedied. To trace the evolution of medical knowledge, the rise and fall of doctrines and theories, the growth of pathological science, the development of rational therapeutics, and the remarkable advances in surgery, would be an arduous but grateful task to one who had the ability, as well as the opportunity, to undertake it. There is much to be learnt from the study of such a fruitful topic, whilst in interest it can have few equals. Pending, however, the appearance of a work of this wide scope, we must be content to receive such minor contributions as the present volumes typify. The author does not lay claim to have written an exhaustive treatise, whilst he deserves credit for having compiled a most interesting, intelligent, and entertaining book. The main basis of it is biographical, the story of the origin and progress of medicine being told in the lives of its more notable professors, from Hippocrates to the present day. In spite of the diligence exhibited in the collection of materials to fill these volumes, we regret that the names of the leaders of the great continental schools, which signalised the early decades of the present century, should only receive the barest mention, attention being almost exclusively bestowed upon the English leaders in medicine and surgery. In respect of earlier times, however, the writer is more cosmopolitan, so that we have accounts of Vesalius, Fallopius, and Eustachius, but Ambrose Paré is dealt with in too cursory a manner to be satisfactory. On the Alchemists and the birth of chemistry there is an entertaining chapter, which contains admirable accounts of the history of Paracelsus, who, in spite of his empiricism, did medicine some service in the introduction of chemical compounds into therapeutics; and also of Jerome Cardan, mathematician and physician, some of whose precepts are reproduced in these pages. In the chapter dealing with English physicians of the sixteenth century, it is rather surprising to find Sir Kenelm Digby, the advocate of the virtues of the sympathetic powder, dealt with in company with such illustrious men as William Harvey and Thomas Sydenham. Surely a more suitable place for him would have been in the previous chapter, which treats of Animal Magnetism, Mesmerism, and Faith Healing. A graphic account is given of Mesmer and his following; but why did not the author pursue the subject to our own day, and tell us how Elliotson was duped, and how at length hypnotism came to be studied scientifically by physiologists and neurologists? The biographical record is very rich in the second volume, and no exception can be taken to the way in which the lives of Radcliffe and Mead, of the Hunters and Edward Jenner, of Baillie, and many others nearer to our own time, are given; but we can imagine that there is room for cavil at the biographical notes of "eminent contemporary practitioners" which conclude the work, for such selection requires more discrimination than the writer has evinced. One very interesting chapter is devoted to the lives of members of the medical profession who have made their mark in literature; such as Sir Thomas Browne, John Locke, Garth, Akenside, Crabbe, John Brown, and Oliver Wendell Holmes. From the goodly list, of which we have only cited a few, we miss one notable name—that of John Keats. Other chapters interpolated in the chronological sequence are those on great Epidemics and on Mesmerism in the first volume, and that on Herbs and Simples in the second. The book contains some inaccuracies of statement, one of the most striking being that the duct which bears the name of Eustachius connects the ear with the thoracic duct, and a few in the matter of dates, and the spelling of names; whilst it will be news to Dr. Matthews Duncan to hear that he has taken up his residence in Bath. Still these are comparatively trifling errors, and the book on the whole is one which will repay the reading, for it is well written and full of spirit, with a very just appreciation of the mingled truth and error that characterise the development of the art of medicine. If, as we infer, the author does not himself practise the "healing art," he is all the more to be congratulated upon the fairness and impartiality, as well as upon the technical knowledge, which he evinces in his lively and interesting pages.

A Commentary on the Diseases of India. By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng., Deputy Surgeon-General H.M.'s Indian Army, &c. London: J. and A. Churchill. 1886.

THIS large and handsome volume of 816 pages is an outcome of a study of Indian disease maintained for thirty-eight years, upwards of twenty-four of which were mainly devoted to clinical observation in Bengal. In publishing this volume, its author has told us in his preface that he brings "to an end a course of observation, thought, and study which has occupied the whole of a professional lifetime"; and his lamented death followed its publication so quickly that a mournful sadness attaches to his words. It is a voluminous book, dealing with a vast number of subjects, and all from the clinical point of view. There is, no doubt, a great deal of information that is not clinical in character—statistical, topographical, and anecdotal to wit; still, it all has a bearing that way, and is indicative of the bent of the author's mind. Dr. Norman Chevers must have resembled, we imagine, a lately deceased statesman in that he was eminently fair-minded and truthful, gentle and erudite. The perusal of this book leaves that kind of impression on the mind. It is the record of a worthy professional life, and contains a large amount of information based upon the results of his own experience and observation, which, by his extensive reading, he was enabled to compare with those of other labourers in the same field.

The Asclepiad. No. 13, Vol. IV.

THE most interesting contribution to this number appears to us to be the biographical one on John Mayow, a neglected genius, of whom a portrait is given. We cannot assent to the classification of purpura hæmorrhagica and the scorbutic diathesis, for the reasons that we are unable to recognise properly the differences between aqueous, saline, and vascular purpura. This division does not commend itself to us on account of its clinical value or its pathological significance. As doubtless the author and editor of the *Asclepiad* attaches some importance to the article which occupies the place of honour in the current number, we may examine his position a little. He states that "the pathological character of this [aqueous] type is special. The blood of the patients who are subject to it is in a state of extreme fluidity, the fluidity being due to an excess of water, so that the colloidal parts of the blood are diluted to an unnatural degree." Of saline purpura we read that there is in this type no deficiency of fibrin, but as a colloidal substance it is held in a fluid state by an excess of soluble saline material. The vascular variety of purpura is said to be characterised by the perfectly natural state of the blood, which coagulates firmly and



Digitized by Google

quickly. There is much to be said for the ingenuity of these views, but when we come to inquire on what scientific data the clinical distinctions are based, the ground on which Dr. Richardson's classification is made appears to us to be of an unsafe and theoretical kind. The Opuscula Practica are of the customary useful kind, and the article on Practical Biometry, or the Measurement of Life in Health and Disease, is of a high intellectual order.

New Inventions.

THE "MATCHLESS" SELF-LIGHTING GAS-BURNER.

THIS contrivance was originally brought out in America, and is now in general use there in all places where an immediate light is wanted for a short time. The lighting is accomplished by means of a small concealed flame constantly alight, but so small that the amount of gas it consumes is imperceptible. Medical men who are liable to be called up in the night will find this appliance most useful, and as its price is moderate and it is easily adjusted, there can be no doubt that it will be extensively used. The patentees and manufacturers in this country are the G. K. Cooke Manufacturing Company, 73, Cowcross-street, E.C.

A NEW PATENT "BROUGHAM HANSOM."

MESSRS. W. AND F. THORN, of 19, Great Portland-street, have under the above name introduced what is practically a single brougham on two wheels. The term "Hansom" is, we think, inappropriate, as this carriage in no way resembles in appearance the familiar two-wheeled cab, over which it has the distinct advantage of being a really comfortable closed vehicle—a desideratum which the Hansom, useful enough in many ways, entirely fails to supply. The driver, instead of being behind, has his box in front, and the passenger enters the cab from the back, the door opening outwards in the middle, and the corresponding portion of the seat being kept raised when unoccupied by a spring. When the passenger is seated, a simple but effectual arrangement ensures that the door cannot become unfastened by accident or from the outside. We have had an opportunity of personally trying Messrs. Thorn's new "Brougham Hansom," and can speak to its comfort and to the remarkable absence of "knee motion." The weight is only 6½ cwt., at least 2 cwt. less than that of an ordinary Hansom, and the cab is very roomy. A little recess between the front windows would afford a convenient place for stethoscope, &c.; indeed, taken altogether, we think that this two-wheeled brougham is likely to prove a very convenient and comfortable carriage for country practitioners.

FATAL ATTACK ON A DOCTOR IN ROUMANIA.—A Roumanian general, thinking that his wife's doctor was to blame for her death, attacked the unfortunate practitioner at a railway station and cut off his nose, a wound which subsequently proved fatal. The irascible general, on being arraigned before a court-martial, explained that he had not intended to murder the doctor! The deceased was an Austrian by birth, and it is probable that some diplomatic correspondence is taking place on the subject. The result of the trial has not yet been published.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THURSDAY, FEBRUARY 17TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

THE Council sat for some time in private to consider a communication from Mr. M'Vail.

Mr. COLLINS moved the following resolution:—"That, in conformity with the request of the Governor and Court of the Apothecaries' Hall of Ireland of November 9th, 1886, already entered on the Minutes of the Council, this Council will proceed to appoint an Examiner in Surgery to entitle the Apothecaries' Hall to issue registrable qualifications in conformity with Clause 5 of the Medical Act, 1886." He asked the Council not to allow the Apothecaries' Hall in Ireland to be without a registrable qualification until the Council met again. The Apothecaries' Hall was quite willing to co-operate with the other bodies, and that desire would still remain even if it continued an independent body. He hoped the Council would nominate an examiner to complete the educational examination of the Apothecaries' Hall.

Dr. HAUGHTON seconded the motion.

Sir WM. GULL pointed out that the Corporation itself ought to have made the application. The motion of Mr. Collins was only a personal request from that gentleman.

Mr. COLLINS said he proposed the motion as the representative of the Apothecaries' Hall.

Sir WILLIAM TURNER said the motion could be put in order by a reference to the letter of the Apothecaries' Hall on the subject.

Dr. LEISHMAN called attention to the peculiar construction of the motion, which was, he said, really a request of of the Examiners and Court of the Apothecaries' Hall, and not in the form of a resolution of the Council itself.

Sir W. FOSTER thought the resolution was premature. It related to a great question which would have to be decided by the Council. The intention of the Act of 1886 was to force combinations on all the corporations of the United Kingdom, and he hoped that that result would be obtained. It was important that the contention between the parties concerned should be settled in a friendly manner. If the motion were passed, Mr. Collins would be in the position of a Bismarck, and would be able to take up an antagonistic position at once. If the negotiations failed, the Council could take the matter into consideration, but at present the granting of the request would not be likely to promote the friendly spirit to which they desired to appeal.

Dr. STRUTHERS moved, as an amendment, "That the Council defer giving a decision on the motion of Mr. Collins, in order to give the King and Queen's College of Physicians, the Royal College of Surgeons in Ireland, and the Apothecaries' Hall in Ireland time to consider the resolution passed by the Council yesterday on the motion of Dr. Struthers."

After some further discussion the motion of Mr. Collins was altered in the following form: "That in conformity with the request of the Governor and Court of Apothecaries Hall, Ireland, of the 9th of November, already entered upon the Minutes of the Council, this Council will proceed to appoint an examiner in surgery, to entitle the Apothecaries' Hall to issue registrable qualifications in conformity with Clause 5 of the Medical Act of 1886."

Mr. TEALE, in seconding the amendment, said that if the question were not settled in a friendly way, the Council would no doubt have to meet again for the purpose of appointing an examiner.

Sir WILLIAM TURNER said that in passing the proposed motion the Council would be stultifying itself. The motion was altogether premature, and the amendment was the only logical sequence to the resolution passed on Wednesday.

Dr. WILLIAM MOORE thought that the Irish bodies should have time given them to consider the question.

Dr. GLOVER asked if there were any chance of the Council receiving an answer from the College of Physicians in Ireland during the present session of the Council. The necessity of another meeting of the Council in June to settle the question would be simply deplorable.

Dr. A. SMITH said there was no possibility of getting an answer from the College of Physicians during the present session.

Mr. COLLINS and Dr. HAUGHTON stated that they would

Digitized by Google

accept the amendment, in the hope that the Council would, if necessary, meet in June to settle the question.

Mr. MACNAMARA said that the College of Surgeons was most anxious to bring in the Apothecaries' Hall. Dr. Kidd could bear him out in that statement.

Dr. HERON WATSON supported the proposal of Dr. Struthers. The Council could not act in the direction required without knowing something of the terms that had been discussed between the bodies themselves. It might, after all, turn out that the Apothecaries' Hall had been unreasonable in its demands.

Dr. QUAIN protested against the further discussion of the matter (Mr. Collins having accepted the amendment), and stated that the Council was sitting at the enormous expense of £1 a minute.

The amendment was then put and carried, and it was also unanimously agreed to as an original motion.

A communication was received from the Lord President of the Privy Council, forwarding a memorial presented to the Lords of the Council by Mr. Laffan of Cashel with respect to the efficiency of the qualifying examinations under the Medical Acts, and requesting the Medical Council to favour his lordship with their observations on the memorial. The memorial called attention to the Report of the Visitors on the Examinations of the Royal University of Ireland, with a view of showing that the candidates for the degrees of the University were shamefully deficient in clinical training. Complaint was also made that the University had declined to recognise the union hospitals for clinical purposes.

Dr. BANKS explained the action of the Royal University in the matter, and read the following regulations of that body: "In the case of a hospital seeking recognition as a school for clinical teaching, the Senate will require evidence that it contains at least sixty beds in constant occupation; that at least ten beds are provided for the treatment of cases of fever; that it possesses a suitable lecture theatre and other appliances necessary for clinical teaching; that a roll of attendance is strictly kept, which shall be open to the inspection of any person delegated by the Senate." He moved that the following resolution be transmitted to the Lord President: "That this Council, having before it the regulations of the Royal University with respect to the attendance of students of hospitals, is of opinion that it is not expedient to take any action on the subject."

Dr. KIDD, in seconding the motion, said it was the opinion of the Royal University and the College of Surgeons in Ireland that the union hospitals were quite inadequate for the due teaching of clinical medicine or surgery. They were receptacles of the aged, the poor, and worn-out subjects not presenting features of active disease.

Dr. HAUGHTON suggested that the matter should be referred to a committee acquainted with hospital teaching, with a view, not of controlling any university or corporation, but of laying down some such principle as that, if the teaching of any hospital school in the country were efficient and the field of practice good, it should be partially recognised.

Sir WILLIAM GULL concurred in the suggestion that the matter should be referred to a committee to report to the Council.

Mr. SIMON, in supporting the proposal, expressed a hope that the committee should not be an exclusively Irish one.

Dr. HERON WATSON also supported the proposal.

Sir WALTER FOSTER hoped that the committee would consider not only the memorial, but all the documents entered on the Minutes in connexion with it.

Mr. MACNAMARA referred to a visit made by him and Dr. Banks to the Galway Infirmary, with the admirable appearance of which they were both greatly pleased. He protested against the allegations made by Mr. Laffan against the honour of the medical men on the Senate of the Royal University, who were men of the highest rank, and wholly above any sordid considerations such as those charged against them.

Dr. BRUCE called attention to the fact that the Act of 1886 had only just come into operation, and said it was hardly time to consider the action of the Council under that Act.

Dr. BANKS expressed his willingness to accept the amendment referring the subject to a committee, and said that the University had acted on the knowledge of the fact that the workhouse hospitals did not provide proper materials for clinical teaching. There was no intention, however, to cast the slightest slur upon the medical officers of those bodies.

Dr. KIDD read a description by the Visitors of the Dublin Hospital, stating that the patients were mostly old and worn-out persons, too stupid or deaf to hear and answer questions, and might almost be regarded as specimens in a pathological museum.

The proposal to refer the subject to a committee was then agreed to, Sir William Gull being the chairman.

Dr. HERON WATSON moved: "That, considering the somewhat anomalous position in which the General Medical Council is placed by the opinion given by Mr. Muir Mackenzie on the clauses of the Medical Act referring to the qualifying examinations held by a combination of medical authorities, and the relation of the General Medical Council to such contracting bodies as may agree to hold qualifying examinations under such scheme, it is desirable that a further opinion from the responsible legal advisers of the Government be obtained before the Council proceeds to take any steps arising out of the interpretation of Sections 15, 18 and 19 of the Medical Act, 1858, construed along with Sections 1, 2, 3, 4, 5, and 6 of the Medical Act, 1886, together with the consideration of any other points which may arise within this reference, and that it be referred to the Executive Committee to take the requisite steps to give effect to this." He said that the opinion of Mr. Muir Mackenzie as to the duties of the Council in reference to combination had placed the Council in a very distressing position. The Council ought to be quite certain as to what constituted a qualifying examination and what it might be required to do with reference to any body excluded from combination; and although not wishing to doubt the ability and acumen of Mr. Muir Mackenzie, he thought that the matter should be referred to the legal advisers of the Government in order that the Council might know the exact position in which it stood and what was the true interpretation of the Medical Acts.

Dr. STRUTHERS seconded the motion.

Dr. A. SMITH thought that the Council should be satisfied with the opinion expressed by Mr. Muir Mackenzie. He moved as an amendment, "That the Council, in accordance with the opinion of its law adviser respecting a Conjoint Board for Ireland, do proceed to the next order of the day."

This amendment was put and negatived.

Dr. MCVAIL said if it should turn out that Mr. Muir Mackenzie was right, he thought it would be desirable that the Council should memorialise the Government to introduce a Bill to give it the power which it had lost. A short Bill with one clause would be sufficient.

Dr. QUAIN brought up the Finance Committee's report, which showed that the income of the General and Branch Councils for the past year was £9741 6*s.* 4*d.*, an amount which was less by £1372 2*s.* 5*d.* than in 1885. The expenditure during 1886 was £8991 3*s.* 3*d.*, which was less by £3092 13*s.* 1*d.* than in 1885. With reference to future expenditure, it was estimated that the enlargement of the Council would necessitate hereafter an increased annual outlay, on account of fees and other expenses, of about £1200.

Sir WM. TURNER said he wished to draw attention to the subject of Dental finance. In January, 1881, the Dentists' Fund amounted to £9824, in 1883 to £9220, in 1885 to £9017, in 1886 to £8445, and in 1887 to £7465. Therefore during the six years it had sustained a diminution of £2359. If that process went on in anything like the same proportion, the vanishing point of the fund was almost within measurable distance. This was an especially serious matter, as the dentists had no representative on the Council. The method of administration was imposed upon the Council by Act of Parliament, and he thought something ought to be done in the way of diminishing the ratio of expenses, so that a balance might be obtained between income and expenditure.

Dr. QUAIN said that if the Council wished to diminish the dental expenditure it must be done at the expense of the medical profession. He quite agreed that some means must be adopted, if possible, to prevent a final catastrophe in connexion with the Dental Fund, but he could not see how the expenditure was to be lessened. The proportion of expenses paid by the dentists had been fixed at one-sixth, but as they were 6000 as against 24,000 it ought to be one-fifth. The dentists were advised originally to allow the Council to appoint a board composed of eminent dentists and of some members of the Council, but the dentists expressed themselves as having so much confidence in the Council that they were perfectly willing to put the whole matter into their hands.

Digitized by Google

If they had accepted the principle of the Duke of Richmond's Bill and appointed a Dental Board, they could have worked with one-tenth part of the expensive machinery.

Dr. A. SMITH said that he believed there had only been one special meeting of the Dental Committee. On all other occasions the business had been transacted as supplemental to that of the Executive Committee.

Mr. MARSHALL thought that the dentists should be encouraged to sever themselves financially from the Medical Council. At present their registration was at a very low ebb, twenty-five or twenty-six a year, but students were coming on to the Register at the rate of from seventy-five to a hundred a year, and therefore in a few years the dentists would have increased resources, and that ought to encourage them to feel that by and by they might be able to run alone.

The Council then adjourned.

FRIDAY, FEB. 18TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

Mr. MARSHALL said he had thought it his duty on the previous day, as chairman of the Business Committee, to ask the Council to suspend the printing of a communication received from Dr. McVail, wishing to see whether any irregularities had been committed. He had now unreservedly to say that there had been no irregularity, and he therefore moved that the letter be now entered in the Minutes.

Dr. HERON WATSON seconded the motion, which was agreed to.

The following is the letter:—

DEAR SIR,—The point of order that I rose to speak to yesterday concerned the commissions of the representatives of the Scottish universities, as read by the Registrar.

These commissions in all four instances are from the Senates of the universities; in three of them this is formally expressed; and in the case of Glasgow, although not definitely stated in the document, yet the Senate alone made the appointment.

I desired to call your attention to the circumstances—first, that the Medical Act of 1886 does not, in the case of any one of these universities, restrict the power of election to the Senate; and second, that the Scottish Universities' Act of 1858 is likewise without any such limiting provision.

I hold that in the Scottish universities the duty of electing the representatives to the General Medical Council falls on the same constituencies that return the representatives to the Imperial Parliament.

I therefore regard the returns read before the General Council yesterday as being quite invalid.

I am, dear Sir, yours faithfully,

To Sir Henry W. Acland, President of the General Medical Council. O. C. MCVAIL.

Dr. HUMPHRY moved, "That a committee be appointed to consider the past and prospective income and expenditure of the Council, and to report to the Council whether any, and, if so, what, diminution can be made in the future expenditure of the Council." In doing so, he said when the Council was first constituted they had to settle the fees and expenses to be paid to the members; therefore one of the first actions of the newly constituted Council should be to take the same subject into consideration. The expenses of the sittings of the Council amounted to about £2000 a year, and any opprobrium cast on the old Council should not be fixed on the new one. The excess of income over expenditure during the past seven years averaged £1400 annually, and the estimated increase of expenditure in the years to come would be £1200. That would bring expenditure and income within close relation to one another. Additional expenses must, however, be expected. It would be an unusual thing for a large number of men to do business in a shorter time than a small number. He therefore thought the Council should seriously consider whether any diminution could be effected in the various expenses.

Mr. WHEELHOUSE seconded the motion, believing that the action of such a committee would be some guarantee to the profession that an eye was kept on the expenses, and that the Council was not inclined to spend its funds recklessly.

Dr. MCVAIL thought that the committee should also consider the question whether the meetings of the Council could not be held in rotation in London, Edinburgh, and Dublin. No one could doubt that there must be some rearrangement with regard to fees, and it would be absurd to propose that they should be reduced below the present scale for gentlemen living out of the country in which the meetings were held. He would therefore move as an amendment that the committee be asked to consider also whether the meetings could not be held occasionally at all events, in Edinburgh and Dublin.

The PRESIDENT ruled that Dr. McVail's proposal was not an amendment to the motion.

Dr. QUAIN strongly opposed the suggestion. There were sixteen English members, and if they had to travel to Scotland and Ireland the expenses would be doubled, and the funds would be utterly inadequate.

Dr. HAUGHTON said he might add the additional reason that the Irish members were so hospitable that if the Council came to Dublin they would be broke in entertaining it. (Laughter.)

Mr. MACNAMARA suggested that the following words should be added to the motion: "And also whether and in what manner its income may be increased." He had very strong views upon the subject as to a method and way in which the income of the Council might be substantially increased, and he should be prepared to state them when the time arrived.

Dr. HUMPHRY said he would accept Mr. Macnamara's suggestion, and add those words to the motion.

Mr. SIMON said the financial position of the Council was only one part of a large subject. The primary question was the organisation of their work, because if their work was well organised he believed that great economies would result. The Council was not nearly strict enough in distinguishing fancy work from statutory work. The Council met for definite duties—happily now much more definite than they formerly were. He had handed in a notice of motion expressing what he thought the better view to take for the present of this finance question—namely, that it be referred to a committee to be appointed to consider under what rules of meeting and procedure and with what appointment and authorisation of standing committees and sub-committees the Council might best provide for the regular, effective, and economical discharge of its statutory duties, the committee to report to the Council at its next meeting and to bring up a draft of any standing orders which it might deem desirable. If a reference of that sort were made, then on the report of the committee the Council would be in a position to reconsider their finances; but at present he thought they were not in a position to do so.

Dr. PETTIGREW agreed with Mr. Simon that the present motion was premature.

Dr. AQUILLA SMITH supported that view.

Dr. BRUCE thought that until they knew what their expenditure was to be they could not deal with ways and means.

The motion, with the addition of the words suggested by Mr. Macnamara, was then carried and the committee was nominated.

Mr. MARSHALL, in furnishing information in regard to some exceptional cases which the Council had directed to be inquired into, said it appeared that twenty-two such cases had occurred at the College of Surgeons and thirty-nine at the College of Physicians, but he wished to point out that a certain number of those were duplicate representations of the same persons. In every instance the men were graduates of Indian, colonial, or foreign universities, and he was prepared to state that they had all studied medicine for the required period of forty-five months.

Sir DYCE DUCKWORTH corroborated Mr. Marshall's statement, and said that all the cases had been carefully scrutinised by the Registrar of the College of Physicians.

Dr. HERON WATSON asked if in the case of graduates of an Indian university English was regarded as a good substitute for a classical language.

Mr. MARSHALL said that it was.

The next subject on the agenda was the final report from the Visitation of Examinations Committee.

Mr. MARSHALL, in moving that it be received and printed, and appended to the Minutes, expressed his deep regret that Dr. Haldane was prevented from being present at this meeting of the Council, and his extreme sorrow at the unexpected death of Dr. Lyons. In addition to a historical summary of facts, the report contained a commentary in which care had been taken not to express decided opinions that would create any adverse criticism, but rather to balance and weigh and see where hints could be obtained for future examinations. The report terminated with a series of "conclusions," not "recommendations."

Mr. TEALE seconded the motion.

Dr. HAUGHTON bore testimony to the extreme accuracy and care with which Mr. Marshall had prepared the report. He thought the committee might perhaps see their way to add a statement as to the sufficiency of the examinations.

Digitized by Google

Dr. STRUTHERS thought it would very much detract from the value of the report if any such addition were made.

Mr. MACNAMARA, while expressing his admiration of the report, said it was very remarkable that the alumni of Trinity College were not thoroughly grounded in Latin.

Dr. GLOVER heartily joined in thanking Mr. Marshall and his colleagues for their enormous labours in regard to the report. At the same time he thought the conclusion of the whole matter was rather impotent and disappointing. Considering the great cost of these visitations, he thought the committee might have given a more definite deliverance, and ventured a little bold criticism in the way of either endorsing the complaints of the Visitors or acquitting the universities. The Privy Council had sent some very serious observations for the consideration of the Council, and unless some reply was given the Lords of the Council would think that the General Medical Council had rather evaded the expression of a definite opinion upon the truth or untruth, the justice or otherwise, of the charges which had been made. It was also a serious thing for it to go forth to the world as presumably the expression of the Council's opinion that prescriptions might be written either in Latin or in English at the option of the candidate, yet Oxford University appeared to be indifferent on this point.

Dr. MCVAIL dealt at considerable length with the details of the report, and quoted the papers contained therein with a view of showing the character of the teaching in the schools, and insisting upon the urgent necessity of the Council going into the matter much more fully than was proposed. He was proceeding to refer to the character of the examinations in operative surgery in the University of Glasgow, when

Dr. LEISHMAN interposed, and said the University of Glasgow was the only body which for the M.D. required examinations in operative surgery. There was no law which obliged them to give any such examination whatever, and he could not submit to the very elaborate attack which was being made upon certain portions of their examinations, which were in excess of what the law required of them. He could conceive of nothing that would be a stronger illustration of a reckless waste of time, but if Dr. McVail was allowed to make his statement, he might have to ask the indulgence of the Council to say a word in defence of his university.

The PRESIDENT said the Council must clearly see that if Dr. McVail's course was pursued it meant an elaborate discussion upon the whole merits of the report.

Dr. MCVAIL said the document required much more consideration than could result from the adoption of Mr. Marshall's motion with regard to the insinuation that he was attacking any university. He said he was speaking of facts alone, and was giving figures that could be got by all the members.

The PRESIDENT having ruled that Dr. McVail could not be heard unless he moved an amendment,

Dr. MCVAIL said he would conclude with the amendment, "That the Council proceed to consider the conclusions of the report *seriatim*."

Dr. QUAIN protested against this expenditure of the time of the Council, and with that of the funds of the profession. (Hear, hear.) The report would be sent to the various institutions for consideration, and that would do infinitely more good than all the discussion that could take place at that Council. He therefore pressed the Council to follow the advice given by the committee to send the papers to those bodies who would be influenced and guided by them, and then to wait the result.

Dr. STRUTHERS said the whole matter had been threshed out at the November meeting.

Dr. MATTHEWS DUNCAN said he entirely disagreed with the general tenour of Dr. Glover's remarks, as well as with those of Dr. McVail. Dr. McVail seemed to think that the opinions of the Visitors carried authority. The Council had never given them any authority; its responsibility ended with sending the Visitors and receiving and printing their reports. This subject had been very carefully dealt with by the Council, and he considered it was a very good resolution that was arrived at that the reports of the Visitors, beyond being responded to by the bodies visited, should not be further dealt with. The Council by the representations which it published had done and was doing an infinite amount of good, and anybody who could give a good picture of the examinations of the Faculty of Physicians and Surgeons a few years ago and contrast them with the present examinations would find the enormous improvement that had been effected in consequence of the representations of the Council.

Mr. MARSHALL protested against the irrelevant discussion raised by Dr. McVail, and said the Council was altogether out of order in going into details till the report had been ordered to be an appendix to the Minutes.

Dr. HERON WATSON said he intended to give notice of motion that the Council should resolve itself into committee on the following Tuesday for the purpose of considering the conclusions of the report in detail.

Mr. SIMON hoped that in that case Dr. Humphry would move the suspension of standing orders with reference to fees received by members of the Council, if that subject was to be gone into.

The motion proposed by Mr. Marshall was then put to the Council and agreed to.

On the motion of Dr. STRUTHERS, seconded by Sir WILLIAM TURNER, the best thanks of the Council were accorded to the Visitation of Examinations Committee, and also to Mr. Marshall for the great labour and care he had bestowed in preparing the report.

The report by the Sub-committee on the Registration of Colonial and Foreign Titles and Foreign Degrees, as adopted by the Executive Committee, was then, on the motion of Mr. MARSHALL, seconded by Mr. SIMON, received and adopted.

Mr. MARSHALL then proposed the following new Standing Orders suggested by the Solicitor, by direction of the Executive Committee, as arising out of the recommendations of the above report:—

(*a*) When an application is made, under the provisions of Section 16 of the Medical Act, 1886, by a medical practitioner—already on the Medical Register by virtue of an English, Scotch, or Irish qualification—to have the description of a foreign degree in medicine possessed by him to be added to his name as an additional title in the Register, the Registrar shall require from the applicant satisfactory proof of the date of the grant of the said degree, and also such further information as may be necessary, in order that the General Council shall be satisfied before the title is registered that the degree was obtained after "proper examination." (*b*) Any application by a registered medical practitioner for removal of his name from the Medical Register shall, in the first instance, be referred by the Branch Registrar to the medical authorities who granted the applicant his qualification or qualifications, to ascertain whether there is any valid objection to such removal. The General Registrar shall bring such application before the next meeting of the General Council, who will consider the application and any objections thereto, and the President may put from the chair to the General Council the question—Whether the Registrar shall erase the applicant's name from the Medical Register. The General Registrar shall, upon the removal of the applicant's name from the Register, send notice of such removal to the applicant by a letter addressed to his registered address.

Mr. SIMON seconded the motion.

Sir WALTER FOSTER said, as the first of these Standing Orders was rendered necessary by a section included in the Medical Act of 1886 on his motion in the House, he should like to have some little understanding of how it would work. In introducing that section, he was anxious that nothing but good sound foreign degrees should obtain access to the Register, and would therefore like to know what steps the Council proposed to take under the new Standing Orders to secure that end.

Mr. MARSHALL said the Registrar would have to be satisfied that the applicant had obtained such degree after proper examination, and prior to the passing of the Act.

The motion was then agreed to, and the Council adjourned.

SATURDAY, FEB. 19TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The Society of Apothecaries and the Conjoint Scheme.

Mr. BRUDENELL CARTER moved:—"That inasmuch as the Master, Wardens, and Society of the Art and Mystery of Apothecaries of the City of London, having used their best endeavours to enter into a combination with some other corporation or university for the purpose of holding a qualifying examination in accordance with the provisions of the Medical Act of 1886, and having reported to the Council that they have been unable to enter into any such combination, have in consequence, and in further compliance with the Medical Act aforesaid, made application to the Council for the appointment of assistant examiners in surgery, the Council do now appoint such examiners accordingly." He said he should have thought the motion would have been nothing more than a formal one, were it not that he had received an intimation that in the judgment of some of the members the precedent which had

Digitized by Google

been set in the case of Dublin ought to be applied equally in the case of London, and that expression of opinion had taken definite shape in the two amendments that had been placed on the programme. It was a very significant matter that the amendments were to be moved by gentlemen who were not resident in the metropolis, and who might therefore be supposed to be not so familiar as some of them with the precise tendencies of the currents of forces which there existed with regard to this matter. The Apothecaries were now, as they always had been, perfectly willing to enter into combination with the Royal Colleges. The difficulty which had arisen had not arisen from them, but on the part of the Royal Colleges. If it was the pleasure of the Council to defer the matter, the Society would not protest against its being so deferred, and if the bodies which had refused to enter into combination with the Society were to come forward and say that in deference to the view of the Council they would reconsider the position, no possible difficulty would be placed in the way of such combination on the part of the Society. It was also due to the Society to say that as a self-respecting body they could not be expected by that Council to approach again those universities or corporations which had already in so decided a manner refused to combine with them. If in deference to the opinion of the Council the question was postponed, then he thought it would be for those other bodies to approach the Apothecaries' Society, and not for the Society, having fulfilled its statutory and moral obligations, to go round to the different corporations once more to receive the same answer. As a member of the Council, he protested very strongly against what seemed to him a waste of time—namely, the proposition to adopt in the case of the London Society the same course as had been done in the case of the Dublin Society, and refer the subject back to the Colleges for their reconsideration. The differences between the two cases of Dublin and of London were very great. The London Society stood in a somewhat stronger position than the Dublin Society, in the fact that its privileges rested upon the wide basis of parliamentary enactment and long usage, and that during the seventy years of its licensing and examination career it had given its licence to no less than 22,000 general practitioners. Then, again, the two Royal Colleges having received the consent of the Council to their present amalgamation, how could the Council go back from the sanction which it had already given to a particular combination and say that that combination was to be altered? He thought it would be useless for the Council to endeavour to put pressure upon constitutional bodies with a union already sanctioned in order to induce them to take into that union a third body which they had already refused. The Council had no *locus standi* whatever, and no power of influencing the results. Another point of difference was that in Dublin the College of Surgeons was willing to admit the Irish Apothecaries' Hall into combination, and the difficulty arose only with the King and Queen's College of Physicians. In London precisely the contrary was the case. The matter had been under consideration for eleven years, and when the conjoint scheme was agreed upon the two Royal Colleges joined hands and excluded the Society of Apothecaries from their combination, and did so in the most deliberate way. Both Colleges were governed by men of profound sagacity and sound judgment, and they must be taken to have considered the matter in all its bearings. Looking at all the facts, he thought it would be utterly useless to refer the question back to them for reconsideration. Referring to the history of the Apothecaries' Company, he claimed that it had fulfilled all the conditions laid down in the Act of 1886. During the seventy years of its existence it had continually raised the standard of medical education. During the first fifty of those seventy years every general practitioner held its licence. During the last five years it had licensed annually 250 persons on an average, and had recently, in compliance with the recommendations of the Council in 1884, added to its examining body examiners in surgery and midwifery. Their examining board was composed of gentlemen of the very highest standing. He hoped that his application would be a merely formal one; in fact, if it was carried he should ask the Council to nominate as examiners in surgery the gentlemen who now filled the post with such distinguished ability.

Dr. [illegible] seconded the motion. The proposition was that the Colleges should do their statutory duty, and he thought they were bound upon to do it without delay. It would be useless to refer the matter back to the Colleges. It was not possible, knowing the deliberate action of those Colleges, to suppose that they would reconsider the question; they had considered it for so many years that they would be wrong in reconsidering it. The proposals, therefore, put forward in the amendments on the programme were simply to defer the question until it was too late to be of use.

Mr. MITCHELL BANKS had given notice of the following amendment: "That the Council postpone coming to a decision on the motion of Mr. Brudenell Carter, and earnestly request the Royal College of Physicians of London and the Royal College of Surgeons of England to reconsider their action with reference to the admission of the Apothecaries' Society of England to a joint examining board."

Dr. STRUTHERS had also given notice of an amendment, seconded by Mr. TEALE: "That the Council, being of opinion that it would be contrary to the interest of the public to have two competing examining boards sitting in London, and that it is desirable that the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Apothecaries' Society of London should arrange to hold a qualifying examination conjointly, strongly recommend to these medical authorities to reconsider their position with a view to such an arrangement; and meantime defer coming to a decision on the application from the Apothecaries' Society of London of 12th February."

Mr. MITCHELL BANKS said the two amendments had practically the same tendency, and he would be glad to merge his with Dr. Struthers', or to abandon it in favour of the latter. He admitted the services which the Apothecaries' Society had rendered to the cause of medical education, but the only reason for its continuance was the memory of its past deeds. It had been suggested that the existence of another examining body would mean a wholesome rivalry, but he thought it would be a competition downwards.

Mr. WHEELHOUSE was prepared to second the amendment. There was among the profession generally a most earnest desire for the suggested combination.

Sir DYCE DUCKWORTH said that in one important particular the College of Physicians had never recognised the Apothecaries' Society as qualifying for its licence. When the two Colleges agreed to combine for the purpose of holding a qualifying examination the Apothecaries' Society was left out of the combination. The Apothecaries admitted that the Conjoint Board of the two Colleges was complete and wanted no adding to, and he was quite sure from the character of the examiners of the two Royal Colleges in the subject in which the Apothecaries claimed to take part, that the examination was second to none, not even to that of any of the universities in the United Kingdom. What did the Society want? They offered to examine in botany, chemistry, and pharmacy. It would naturally be asked, Who were the men whom the Apothecaries' Society would be likely to appoint to those important functions. Far from being able to find amongst its own members persons qualified to examine, they had to go outside and take six or seven of the Fellows of the College of Physicians to do the work for them. In preliminary and scientific subjects the two Colleges took the greatest pains to secure examiners of the first eminence, and he did not see what particular benefit would result from granting the claim of the Apothecaries' Society. It would be a great disaster to have another competing licensing body. A good deal had been said about the dignity of the College of Physicians. It was a body which respected itself, and therefore respected all other bodies. He was authorised to say that it was absolutely useless to refer the matter back to the College, because he was perfectly certain that its deliberate action would be sustained.

Dr. STRUTHERS said he had very serious objection to sending a body of men out into the profession with the title simply of Licentiates of the Apothecaries' Society. It might be that the Privy Council would yield to the request, but he himself could never be a party to lending crutches to the Apothecaries' Society.

Sir W. FOSTER, as a direct representative of the profession, opposed the multiplication of portals to the profession.

Dr. HAUGHTON thought the Apothecaries had made out a fair case for considering what examiners should be appointed, and should therefore vote for the resolution.

Mr. SIMON hoped that the two amendments would be amalgamated.

Mr. TEALE seconded Dr. Struthers' amendment, and after

Digitized by Google

a short discussion Mr. MITCHELL BANKS withdrew his amendment in favour of that by Dr. Struthers.

Dr. GLOVER regretted exceedingly that at the advanced stage of the proceedings of Council they were spending three hours in discussing a question which ought not to have presented any difficulty. He should be no party to asking the Apothecaries' Company to put itself into the attitude of knocking at the doors of all the corporations and universities of England again. It had gone through a process very painful to those who held its licence, and certainly they could not ask it to continue that attitude. The profession had never been in such a complicated state as at present, when they had universities competing with corporations, and corporations desiring to assume university functions, while the united Colleges were repeating the action of the College of Physicians in 1815—that of disregarding a very extensive feeling in the profession that the body which had had so much to do with the general practitioners ought not to be treated coldly, nor, at present at any rate, to have its existence discontinued. The situation was still further complicated by the Act of 1886, which did not appear to give the Council the power which it had hitherto possessed of expressing its opinion upon conjoint arrangements. They might assume, however, that the Royal Colleges would not disregard the strong expression of opinion of the Council, and he therefore hoped that Dr. Struthers' amendment would be adopted. The Council might only get another proof that it had lost its power, but the sooner they got that proof the better.

Sir DYCE DUCKWORTH asked Mr. Carter what was the significance of a rather minatory clause in the letter addressed to the Royal Colleges of Physicians and Surgeons, which did not appear in any of the letters addressed to the universities—viz.: "Nor should it be forgotten that, if the Colleges be unwilling to combine with the Society, there is still open and possible to the latter a very formidable combination, which in this alternative would equally cause a very serious competition to arise, to the prejudice of the Colleges."

Mr. CARTER said that the letter was written before he was the representative of the Society, and he had no knowledge of what was in the mind of the writer. The applications made to the Universities of Oxford and Cambridge were regarded as merely *pro formâ*, but it was thought possible that those addressed to the Victoria and Durham Universities might lead to combination, and a deputation was sent to Durham to discuss the matter with the authorities.

Mr. MARSHALL said that he felt a difficulty, owing to the position which he occupied in relation to the College of Surgeons, in voting for the amendment, and at the same time he could not oppose it. As a member of the Council, his sympathies were in favour of the amendment. The argument now brought forward was, not that it was necessary for the purposes of examination that the Society of Apothecaries should be taken into the Conjoint Scheme, but that it was necessary for the public good; and that was an argument that, as an honest member of the Council, he could not oppose. Under those circumstances he thought it best to give no vote on the subject.

Dr. DUNCAN said that, while intending to vote for the amendment, he entirely disapproved of the tone of many of the remarks that had been made. He saw no reason for the mock humility displayed by Mr. Carter in reference to the Society of Apothecaries, which might hold up its head as an equal with the Colleges of Physicians and Surgeons, and not as an inferior. Though he proposed to vote for the amendment, he was no advocate for the one-portal system, which he thought was the worst of all systems. Competing bodies he considered to be of great advantage. But there would be a benefit, in the present crisis of affairs, in the union, not the absorption, of the Society of Apothecaries with the two Colleges. It had been said that if the Medical Council did not do it the Privy Council would. He did not take that view. He had no doubt that the Privy Council would treat the decision of the Medical Council with profound respect. If he thought that the exclusion of the Society of Apothecaries would tend to a competition downwards, and to a lowering of the qualification, he could not vote for its continuation. But its past history had shown that it had generally kept pace with improvements in teaching and examination. One of his reasons for voting for the amendment was that if the Council now appointed examiners for the Society of Apothecaries in England the Colleges in Dublin would hardly listen to the advice which had been given to them, and to which he hoped they would listen.

Dr. HUMPHRY agreed with Dr. Duncan that in rejecting the amendment the Council would be acting inconsistently with the vote it had passed in reference to the Apothecaries' Hall in Dublin. But he had no great hope as to the result.

Dr. BANKS supported the amendment.

Mr. B. CARTER, in replying, said he believed that the power to compel combinations was designedly withheld from the Medical Council. The power of appeal to the Privy Council was inserted at the request of the Society of Apothecaries. He wished to ask what security the Society had that the Council would meet in May, because unless there was some assurance to that effect it might be their duty to appeal before that date. They had acquired a vested interest in English medical education and examination, and no Government or Parliament would ever dream of extinguishing it without compensation.

The amendment proposed by Dr. Struthers was then put to the Council and carried, 24 voting in its favour and 4 against.

Mr. BRUDENELL CARTER asked what course would be taken with regard to the resolution just agreed to.

Sir WM. TURNER said he was just about to ask the same question, not only with regard to this matter, but also as to communication with the Irish bodies.

The PRESIDENT said after consultation with the Chairman of Business he should be prepared to suggest the course that should be taken at their next sitting.

On the motion of Mr. SIMON, seconded by Mr. MARSHALL, it was resolved: "That it be referred to the Business Committee, with six additional members to be appointed by the Council for the purpose of the reference, to consider under what rules of meeting and procedure, and with what appointment and authorisation of standing committees and sub-committees, the Council may best provide for the regular, effective, and economical discharge of its statutory duties; the committee to report to the Council at its next meeting, and to propose for consideration of the Council the draft of any new Standing Orders which it may deem desirable."

Dr. HERON WATSON then moved: "That, having received the final report of the Visitation of Examinations Committee, the Council determine that it resolve itself into a committee to consider the report of the Visitors appointed by the General Medical Council, together with the answers of the several universities, in the light of the report, and that it do so resolve itself into committee upon Tuesday next." He said he moved the resolution simply with the view of putting the Council in line with the mode of procedure adopted in connexion with previous reports of visitations. The report in question was of a most admirable character, and it would be a pity for it to be handed over to a remote shelf of the office without any further expression of opinion on the part of the Council with regard to it.

Dr. BANKS seconded the motion.

Dr. AQUILLA SMITH thought the motion a very undesirable one, because if the Council resolved itself into committee it was impossible to say how long the discussion would last. There was no necessity at all for it, as all good that could possibly be derived from it would arise from its study by the various bodies.

Dr. HUMPHRY also opposed the motion.

Dr. BRUCE moved as an amendment: "That, in receiving the final report from the Visitation of Examinations Committee, the General Medical Council is happy to find that all the universities do provide a sufficient guarantee that their graduates possess the requisite knowledge and skill for the efficient practice of their profession."

Dr. HAUGHTON seconded the amendment, and moved the adjournment of the debate.

Dr. STRUTHERS gave notice that at the next sitting he would move the previous question.

The Council then adjourned.

MONDAY, FEBRUARY 21ST.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The Apothecaries' Societies and the Conjoint Scheme.

The PRESIDENT said that, in accordance with the wish of the Council, he had consulted with the Chairman of Business and also some other members of the Council as to the mode to be adopted in bringing the resolutions of the Council before the Royal Colleges, and, with the permission of the Chairman of Business, a resolution would be moved on the subject.

Digitized by Google

Dr. STRUTHERS proposed: "That the President be requested to communicate to the King and Queen's College of Physicians and the Royal College of Surgeons of Ireland, and the Apothecaries' Hall of Ireland, the resolution of the Council of Feb. 16th, and to communicate to the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London, the resolution of the Council of Feb. 19th, and to take such further action as he may see fit towards the attainment of the object of those resolutions, to which the Council attaches great importance, in the interest of the public."

Mr. WHEELHOUSE seconded the motion.

Dr. AQUILLA SMITH could not agree with the motion. He objected to the idea of personal influence being brought to bear, which seemed to be the object of the resolution, and at the same time thought it would be very unfair and very unreasonable to impose upon the President the duty of entering into oral communication with these Colleges.

Mr. BRUDENELL CARTER said he should move an amendment—viz.: "That the letters, if any, to the Royal College of Physicians, London, and the Royal College of Surgeons, England, be addressed to the Presidents of those Colleges respectively, with the request for immediate reply, and that those replies be considered by the Council during its present session."

Mr. MARSHALL said, if an amendment was to be moved, it could not be be discussed without being on the programme.

The motion and amendment were therefore adjourned to the following day.

Dr. BRUCE then moved the amendment (of which he had given notice) to the motion of Dr. Heron Watson with regard to the report of the Visitation of Examinations Committee. He said they had had a valuable report from the committee, and it was quite unnecessary to go over again all the points raised in that document. Indeed, it would not be courteous to the committee to do so; and no one would care to sit upon a committee if every point discussed by it was taken up again by the Council. Unless Dr. Watson was prepared to move an amendment to some of the rules and regulations of the Council, which would be the logical sequence of his proposal to go into committee, the course he had suggested would be a mere waste of time. It had often been said to the direct representatives on the Council during the progress of their election that they ought to take care that no man who was not a gentleman and had not the making of a good doctor in him should be admitted to the profession. But that was not the function of the Council. No resolution of the Council and no Act of Parliament would make a man a gentleman. The Council was not a patent machine for turning out irreproachable doctors. All that it could do was to see that candidates came up to a certain minimum in their examinations.

Dr. HAUGHTON, in seconding the amendment, said it had not been proved to the satisfaction of the Council that any one corporation or university in the three kingdoms was letting loose upon the world men who were not safe practitioners. That was their business, and that alone. On reading over the reports, he did not see that any case had been made out to satisfy any individual member, much less the Council as a whole, that in any instance these bodies had passed men who were incompetent to practise.

Mr. SIMON said he could vote neither for the motion nor the amendment. The amendment stated that the amenders were "happy to find." He rejoiced in their happiness. (Laughter.) They were happy to find what, in point of fact, was not to be found in the report. On the contrary, he was correct in saying that in the Visitors' report there were passages as strongly as possible in an opposite direction, and in three cases it was stated that the degrees ought not to admit to the Register. He did not think it would be right to meet this with the "previous question." Here were three courses proposed, and he thought the Council could not take any one of them. There was a fourth course, although that was going beyond the usual quantity of option, and perhaps it would not be irregular if he read what he thought that course should be: "That the Council, intending shortly to begin its inspections under the Medical Act of 1886, will, when it enters on that duty, particularly direct the attention of its inspectors to all points at which the late Visitors of the final examinations of the universities take exception more or less to the sufficiency of certain of those examinations, and will on the same occasion take a like course in respect of the reports which it last received on the examinations of the medical corporations."

Dr. MATTHEWS DUNCAN said he should be prepared to second that amendment.

Sir WM. TURNER agreed that the two amendments before the Council hardly met the motion, and was quite prepared to support Mr. Simon's amendment. He could not accept what he understood to be the proposition laid down by Dr. Heron Watson—viz., that these various documents had not been properly discussed in the Council, because on page 3 of the revised reports he found that the documents which the committee had before it consisted of certain instructions prepared by order of the Medical Council for the instruction of their Visitors; secondly, of the reports of the Visitors; and, thirdly, of the discussions held on June 7th, 8th, 9th and 10th, in committee of the whole Council. He could not see any reason at all why Dr. Heron Watson should now ask them to go into committee on documents on which the Council had sat in committee on four full days in the month of June. He submitted that the Council ought not to take up such a position as to render it necessary for members to remain away from their home duties any longer than was absolutely necessary.

Dr. BRUCE said he was willing, with the permission of the Council, to withdraw his amendment in favour of that proposed by Mr. Simon.

Dr. STRUTHERS said he had intended to move the previous question, but he would refrain from doing so, in favour of Mr. Simon's amendment, if it could be disposed of without waste of time.

Sir W. FOSTER said he would himself move the previous question in the interests of economy of time, which had been for days past neglected by the Council.

Dr. MOORE said he would second the previous question.

The PRESIDENT ruled that the previous question could not be moved until Mr. Simon's amendment (which had been substituted for Dr. Bruce's) had been disposed of.

Dr. GLOVER contended that the subject had not been fully disposed of at the last meeting of the Council, but had been distinctly postponed. If there was one party in the Council more than another that should have favoured the fullest discussion of the reports of the university examinations, it should, he thought, be the representatives of the universities themselves. The amendment of Dr. Bruce (which damned the universities with faint praise) was a very inadequate outcome of the visitations which had taken place by men of the highest eminence. In one of the reports it had been distinctly stated that the examiners had erred on the side of leniency, and in three cases, as Mr. Simon had pointed out, the examinations were not considered sufficient to guarantee the requisite knowledge on the part of the persons passed. Under those circumstances time was not being wasted in properly disposing of the reports. He should, however, vote for Mr. Simon's amendment, seeing that the Council was about to turn over a new leaf and to undertake very critical inspections with a view of securing a more severe standard than formerly existed.

Dr. MCVAIL said that the majority of the Council had evidently made up their minds not to deal with the reports, because if any opinion were given by the Council a number of institutions would be severely censured before the profession and the public. ("No, no.") If there was any waste of time, it would be in not considering the reports, the drawing up of which had involved so much trouble and expense.

Mr. MACNAMARA said he accepted the principle of Mr. Simon's amendment and should vote in its favour.

Dr. LEISHMAN said that Mr. Simon's amendment had relieved him from a great difficulty. He sympathised with a good deal of Dr. Heron Watson's statement, but if the subject were to be fully discussed, he did not know when it would be ended. With regard to the University which he himself represented, nothing would give him greater pleasure than to hear anything that could be said against it, provided he had the right to reply. He repudiated the idea of being influenced by any such motive as had been attributed to the representatives of universities.

Dr. BANKS stated that one of the three cases cited by Mr. Simon had reference to the University of Dublin, and that in that case the examination was for physicians, and not for general practitioners. The visitors stated that they were favourably impressed with some portions of the examinations, and could conscientiously commend the specially medical portions.

Sir WALTER FOSTER said that the statement made by Dr. Banks was a good illustration of the fatal course on

Digitized by Google

which the Council was entering in discussing the reports. If all the points were to be taken up in the same way there would be no end to the discussion. They were, in reality, doing nothing more than discussing an entire Blue-book.

Dr. DUNCAN said that some members of the Council had entertained the false impression that the reports had not been already discussed. In truth, they had been considered for a period of four days at the June sitting of the Council.

Dr. STRUTHERS said that the whole subject had been thoroughly threshed out, and he repudiated the insinuation that he was afraid of further discussion.

Dr. HERON WATSON having briefly replied, Mr. Simon's amendment was put and carried, and it was also carried *nem. con.* as a substantive motion.

The next business was the following motion, of which notice had been given by Mr. Teale: "That in the opinion of the General Medical Council it is desirable—(*a*) That, in the interest of students whose place of medical education is at a distance from the seat of examination, the written portion of the examination should be conducted at the place of education; (*b*) that a sufficient time should intervene between the written and the oral portions of an examination to allow the examiners to read over and judge the written answers of every candidate, and to confer upon doubtful cases before the commencement of the oral examination; and (*c*) that candidates who in the written examination have failed so completely as to have forfeited all chance of passing by the aid of the oral shall be 'stopped' from passing on to the remaining portion of the examination. This step ought to be granted as a matter of economy of money in the cases of students, and as a matter of economy of time in the case of examiners."

Mr. SIMON rose to order. He said it was the duty of the Council to mind its own business, and this was not its business. It was a question in contest between parties independent of them, and over whom they had no control. It was merely as to questions of internal economy between independent examining boards and their students.

The PRESIDENT ruled that the motion was in order. It was merely another form of recommendation, and that was a matter quite within the province of the Council.

Mr. TEALE, in moving his resolution, said that in order to shorten the proceedings he would reduce it to the first paragraph. This was a subject clearly within the cognisance of the Council, inasmuch as there were remarks of the Visitors of corporations in which it was referred to very distinctly as an opinion which they had arrived at during their visitations. He urged that a step such as he proposed would be of great value in certain portions of the kingdom, but it would be of most conspicuous value in England, because a great number of students were licensed every year by the two great corporations in London, and a very large proportion of students were educated at a great distance from London, which involved on each occasion of examination a necessity for coming up from their proper work and remaining in London for some days till the oral examination took place. Students were now brought up for their first or semi-first examination early in the course of their first year, when their examinations might possibly be divided into seven different portions, so that students might have to come up seven different times. A memorial had been made on this subject to the examining bodies initiated by the medical department of the Yorkshire College, and signed by other teaching bodies. If there was one thing that struck the Visitors more than another, it was that examining was becoming more laborious, and if done well would require much longer time, and therefore if time could be gained from the paper examination and given to the oral it would be a great advantage to the students; he therefore hoped that the Council would accept the resolution.

Mr. MITCHELL BANKS seconded the motion. He thought that in justice to the provincial students in England some means should be adopted by which their examinations might be lightened. Examination papers could be easily and safely sent through the Post Office, and the heads of the colleges and schools might be thoroughly trusted to see that the examinations were fairly conducted.

Dr. MOORE said that there were practical difficulties in carrying out Mr. Teale's proposal. Students sometimes, while writing their papers, would ask for some explanation respecting a question, and if the examiner were not present the explanation might not be satisfactorily given.

Dr. HAUGHTON said that in Dublin it was always considered necessary to have the examiner present at an examination for honours; but that was hardly necessary in the case of a pass examination.

Dr. DUNCAN said he had never known a student undeservedly rejected, but he had known some students undeservedly passed. The plan recommended by Mr. Teale had been adopted by the University of London and other bodies, including the Obstetrical Society of London, and had been found to work satisfactorily.

Dr. BANKS referred to the dangers attending the transmission of the papers. In order to obtain absolute security in this regard, the authorities at Trinity College, Dublin, had decided to have a printing press on the premises.

Mr. WHEELHOUSE said there was a very strong feeling amongst provincial students that injustice was done them in regard to their written examinations. Even when there was no chance whatever of their passing in their written papers they were detained in London for days to go through the oral examination, which could only be a farce. The present method, he considered, added at least £10 to the cost of a diploma for a provincial student.

Dr. HERON WATSON moved the previous question, and said he considered it a waste of time to discuss the subject. Application should be first made to the Colleges, and distinct evidence should be given of any injustice done to the students. When that was done, the Council might be in a position to take steps in the matter.

Mr. SIMON seconded the motion for the previous question.

Dr. HUMPHRY pointed out certain practical difficulties which, he said, would arise in carrying out Mr. Teale's proposition. He considered that it would be very undesirable to prevent a student from coming up to the oral examination in consequence of his failure at the written examination. Nothing could give a student more permanent information than that which he obtained at an oral examination.

Sir DYCE DUCKWORTH said this question had already come under the consideration of the Colleges in London. There was little doubt that after due deliberation some course of action would be decided upon. He did not agree with Mr. Teale's motion. He believed it was a very good thing for the students to come up to the Colleges and to see London. He was somewhat surprised to learn for the first time that there was a want of confidence as to the manner in which the proper work in the examinations was conducted by the examiners on the Conjoint Board. As one of those examiners, he could only say that an amount of time was given by examiners to their work which perhaps would surprise some members of the Council. The papers were most religiously and carefully read, at a very great expenditure of time, and no candidates were rejected on any one paper. Practically it came to this, that in each subject every man had a *vivâ voce* examination.

Mr. SIMON, while sympathising with Mr. Teale's motion, thought the Council had no authority with the licensing bodies in this matter.

The vote was then taken on the previous question, which was carried by 11 votes against 9.

On the motion of Mr. MARSHALL, seconded by Dr. HERON WATSON, the report of the Executive Committee in regard to Dr. Day was adopted. The committee recommended that "before proceeding further in the matter, it would be desirable to refer the papers on Dr. Day's case, with the Report on the Uses and Abuses of Unqualified Assistants presented by the committee appointed by the General Council on July 3rd, 1882, and the resolution passed by the Council on April 21st, 1883, to the Privy Council, and to communicate the result of such reference to a future meeting of the General Council."

Mr. MARSHALL then moved: "That the diplomas in Sanitary Science, Public Health, and State Medicine, granted after examination (see pp. 46-71 of the Minutes for Feb. 15th, 1886) be recognised by the Council for purposes of Registration in the Medical Register, under Section 21 of the Medical Act, 1886."

Dr. HAUGHTON seconded the motion.

Dr. GLOVER asked if anything could be done to introduce something like uniformity in the titles.

Mr. MARSHALL said they had taken a legal opinion on the subject, and were distinctly instructed by their solicitor, and also by Mr. Muir Mackenzie, that they had no power in the

Digitized by Google

matter. They were compelled to use the title that the body itself used. If it was an evil, it was not an evil of the Council's creation, and it was not for them to exercise any influence on the matter.

Dr. HERON WATSON read a letter from a graduate of science with reference to the subject under discussion. It pointed out that in one of the bodies granting diplomas in public health—viz., the University of Edinburgh—residence was required, and a special course of study in laboratory work; while in many others that was not required, so that any registered practitioner could present himself for examination when he felt competent to do so. If a man were put to the trouble and expense of residence for a degree, the writer considered that the degree should not rank with certificates not so obtained. He would call each degree or certificate by the title given it by the authorities. Dr. Watson thought it would be a misfortune to depart from the plan hitherto followed in the registration of other qualifications.

The motion was agreed to.

Presentation to the President.

Dr. HUMPHRY said the very agreeable duty had been deputed to him of offering a marble bust to the President for his acceptance. That bust, executed by M. Boehm, was presented by the members of the late Council and others who had at various times sat under Sir Henry Acland presiding at that table; of those, alas, some were unable to be with them in their bodily presence, of whom he might name Dr. Scott Orr, Dr. Apjohn, and Dr. Storrar. The mention of those names recalled the names of others who also had at still earlier periods sat at that table—Dr. Embleton, Dr. Allan Thomson, Sir Dominic Corrigan, Dr. Rolleston, Dr. Sharpey, and Dr. Andrew Wood,—and there could be no doubt that every one of those would have rejoiced in any opportunity of doing honour to their President. There was no person who had been so identified with the work of the Council up to the present, and it was scarcely probable that any other person ever could be. Ever since its first institution in the year 1858 he had been a member of it, and for more than twelve years he had been its president. The presentation was made as a mark of their high regard for their President as such, and their no less high esteem for him as a man. It was also a token of the general wisdom of his administration in that chair, and of the untiring, continuous, unselfish devotion which he had given to the work of the Council. Dr. Humphry also referred to the work carried on by their President in the University of Oxford, where it was he who first opened the springs of natural science, which afterwards flowed to Cambridge, while from those two universities fountains had been opened in various parts of England, which had done much to promote a higher and more extended education. He concluded by assuring the President that whenever he should cease to bear that honoured name he would be remembered with affection and regret.

The PRESIDENT, in acknowledging the gift, referred to his long connexion with the Council, and said it was rather remarkable that, considering the uncertainty of things here, he had never been absent from any sitting of the Council except on one day when he was obliged to be at Oxford. Referring to the origin of the Council and the strange feeling with which they met for the first time in the history of their profession to endeavour to heal its feuds and foster the good of future generations, and remembering the men who sat on those earlier councils, Brodie and Green, and Christison, Watson, and Corrigan, and those who succeeded them, Parkes and Begbie and Rolleston, they might well understand that it was with truth that he said that the greatest gratification of his life had been the feeling that he was a member of that body. He intimated that from considerations of health he should be obliged to retire from his presidency, but was likely to retain office until the next meeting if necessary, in order, if possible, to bring about some settlement of the difficulty in connexion with the Conjoint Scheme. In conclusion, he asked the favour of the Council to accept the bust, and allow it to remain in the Council room.

Dr. HUMPHRY, on behalf of the Council, accepted the bust, and said that they hoped shortly to add to it the bust of Sir Henry's predecessor, Dr. Paget, so that both universities might be fitly represented.

A vote of thanks having been passed to Dr. Humphry and also to Mr. Boehm, the proceedings terminated.

TUESDAY, FEBR

SIR HENRY ACLAND, PRES

On motion put from the ch
to remove the qualifications
Edward Robson from the M
tions having already been
Physicians and Surgeons in

The Apothecaries' Societies a

Dr. STRUTHERS moved: "That the Pres
communicate to the King and Queen's College o
in Ireland, the Royal College of Surgeons in Irela
the Apothecaries' Hall of Ireland, the resolution of the Council of February 16th; and to communicate to the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London, the resolution of the Council of Feb. 19th; and to take such further action as he may see fit towards the attainment of the object of these resolutions, to which the Council attaches great importance in the interest of the public." He said it was not to be supposed that the President should exercise any undue influence or pressure, but if he would kindly undertake these good offices it might be of very material service to the bringing about of a harmonious solution of this very important point. In looking over the letters that had passed, he thought he saw a ray of hope, notwithstanding all that had been said.

Mr. WHEELHOUSE seconded the motion. The matter was one of very great importance to the profession at large, and in trying to carry it to a successful issue the Council should leave no stone unturned.

Mr. MACNAMARA, while sympathising with the desire that had been expressed, was afraid that hope had told a flattering tale. From letters which he had received from Dublin, he feared that the two Colleges would not listen to the charmer, "charm he never so wisely."

Dr. A. SMITH asked whether the letters were from Fellows of the College of Physicians or of the College of Surgeons.

Mr. MACANMARA said they were from well-informed people (laughter).

Mr. B. CARTER proposed an amendment omitting all reference to the English bodies. He contended that any efforts in relation to those bodies would be a waste of time on the part of the Council, and might inflict serious injury on the Society of Apothecaries. It was necesary that that Society should have ready by June 1st an examination which might with confidence be submitted to the Council, and examiners would have to be appointed either by the Medical Council or the Privy Council. The time, therefore, would have to be fixed—a time beyond which the inaction of the Council would be interpreted as a refusal, and when application would have to be made to the Privy Council. It was not right to hang up the Society of Apothecaries between heaven and earth, like Mahomet's coffin, between the present time and the next meeting of the Council, whenever it might happen to be. The Society did not object to competition, but it claimed to be treated with simple justice. The proposed delay would be a profligate waste of time, and the efforts made would be absolutely futile.

Dr. HAUGHTON, in seconding the amendment, said he had hopes with regard to Dublin; but from all he had heard in England he thought that the proposed action would be a mere waste of time.

Sir W. FOSTER opposed the amendment on the ground that the Council had no right to look outside its own body in the matter. They were custodians and guardians of the interest of the public, and must leave aside narrow views as to the advantages likely to accrue to any individual body by their action. He could quite understand that the Apothecaries' Society would be delighted to be put in an independent position, but he thought the Council ought if possible to prevent it.

Sir WILLIAM TURNER said the Council had already seriously considered all that was involved in Mr. Brudenell Carter's amendment, and therefore his impression was that the whole of this was out of order. The Council had come to a deliberate resolution to go to these various bodies both in England and in Ireland. Having done so, they ought not to pass this amendment, which would practically reopen the whole question, because if it were accepted the next step that Mr. Carter would take would be to bring forward a resolution asking the Council to appoint examiners, when it had already decided that it could not do so this session.

Digitized by Google

which
If a
the
in
bodies.

Mr. SIMON thought the Apothecaries' Company would be ...te equal to making a provisional arrangement on ...une 1st in the event of an adverse decision from the other

Mr. MITCHELL BANKS hoped that the amendment would not be carried, because it was simply an undoing of all that had been done.

Dr. HERON WATSON said the Council would only be stultifying itself if it did not do something to carry out the resolution which it had passed. As to the question of delay, there was no likelihood of the Privy Council acting in the matter without consulting the Medical Council. After such consultation he thought there would be no difficulty in making the necessary arrangements for the examinations.

Dr. STRUTHERS, in replying, said he had no reason to suppose that the efforts of the Council and the President would be useless. He could not believe that a resolution of the Council passed by a majority of 20 against 4 would be disregarded by the Colleges. The object of the motion was simply to carry out the resolution.

Mr. BRUDENELL CARTER thought it would best harmonise with the general feelings of the Council if he withdrew the amendment.

The amendment having by leave been withdrawn, the motion as proposed by Dr. Struthers was agreed to.

Inspection of Examinations.

The next business was to consider the report by the Inspection of Examinations Committee.

It being resolved to deal with the resolutions in the report *seriatim*,

Mr. MARSHALL moved the adoption of the first resolution: "That the principle on which the Council's visitation and inspection of examinations ought to be founded is, that the visitations and inspections shall systematically cover, within stated periods of time, the pass examinations in all branches of knowledge which the Council deems essential as qualifications for licence."

Dr. HERON WATSON seconded the motion.

Dr. DUNCAN said the Act of 1886 distinctly confined their inspections to the three branches of "medicine, surgery and midwifery," and therefore to state that they should cover "all branches of knowledge" introduced confusion.

Dr. KIDD said it was not possible to secure the requisite knowledge of surgery if they did not ascertain that the student was taught anatomy, or that he had the requisite knowledge to practise as a physician without ascertaining whether he had been taught physiology and pathology.

Dr. DUNCAN said that might be true, but it was not an answer to the words of the Act, which did not include many branches of knowledge which the Council rightly deemed essential. The meaning of the Act was plainly that inspections should be confined to examinations of medicine, surgery, and midwifery, and he would therefore move as an amendment that, instead of the resolution reading "past examinations in all branches of knowledge," it should be "past examinations in medicine, surgery, and midwifery."

Dr. QUAIN hoped that such a small matter would not be discussed by the Council on that which they hoped would be the last day of their sitting. It was sheer waste of time.

Mr. SIMON said that the power of visiting courses of study and attending at examinations under the Act of 1858 still continued, but in regard to examination it was merged in the new power of inspection. The phrase "visitation of examinations" was therefore misleading. The reference to the committee was in relation only to the new power of inspection.

Dr. HUMPHRY said that the new Act commanded the Council to appoint inspectors to ascertain the sufficiency of the standard of proficiency required of the candidates at the said qualifying examinations, which were examinations in medicine, surgery, and midwifery; and it was not certain that the inspectors were at liberty to attend any other examinations than those in the three subjects named. It was not certain that Mr. Simon's view was correct, that the old power was merged in the new. Under all the circumstances, it would be better to use the powers of the two Acts.

Dr. Duncan's amendment being withdrawn,

Sir WILLIAM GULL proposed as an amendment—"That the Council's visitations and inspections, imposed by Section 19 of the Act of 1858 and Section 20 of the Act of 1886, shall be systematically performed within stated periods."

Dr. HUMPHRY seconded the amendment.

Dr. BRUCE thought it would be better to omit the first resolution altogether. He proposed to move to that effect.

Dr. STRUTHERS supported that suggestion.

Dr. HERON WATSON said the resolution before them was dependent upon the interpretation which was to be placed upon the two Acts of Parliament on which they acted, and he believed the wording of that first resolution was adopted in committee for no other reason than to keep that as an open question. It was the expression of a general principle, and the subsequent resolutions worked out the details. It was therefore important to press the resolution.

The amendment was then put to the Council and lost.

Dr. BRUCE then moved the previous question, which was seconded by Dr. STRUTHERS.

The previous question was put and lost.

The motion for the adoption of the first resolution was then agreed to.

Mr. MARSHALL moved the adoption of Clause 2: "That, reserving for future action the visitation and inspection of the examinations in the earlier subjects of professional education, the first year's appointment of inspectors provide for the inspection of examinations in medicine, surgery, and midwifery."

Dr. HERON WATSON seconded the resolution, which was adopted.

Mr. MARSHALL moved the adoption of Clause 3: "That each inspector to be appointed for any purpose of the preceding resolution (2) be appointed for all three divisions of the United Kingdom."

Dr. STRUTHERS seconded the motion, which was agreed to.

Mr. MARSHALL then moved the adoption of Clause 4: "That the Council appoint one inspector representing medicine, one representing surgery, and one representing midwifery—three inspectors in all."

Dr. MCVAIL asked whether, looking to the number of bodies to be inspected, it was considered that three inspectors would be sufficient.

Mr. MARSHALL said the committee had taken that important subject into consideration. It was felt that they could not afford to pay more than three inspectors during the first year, and hence the inspection was limited to those three subjects. With regard to the work they had to do, there were fifteen bodies only to be examined in the three divisions of the kingdom, and those fifteen bodies surely could be inspected in the course of the twelve months.

The resolution was agreed to, as were also the subsequent resolutions: "That, previously to making appointments, the Council invite suggestions concerning them from each Branch Council. That each inspector make, from time to time, such inspections of the examinations in his special subject, held by the several licensing bodies in the United Kingdom, as may enable him to form an opinion upon, and report to the Council as to the sufficiency or insufficiency of, those examinations; and, further, that he enter in a diary the date of and the time occupied in each inspection, and any observations that he may think fit, and present this diary, with a report as to the sufficiency or insufficiency of the examinations of each body so inspected by him, to the General Council annually or at such times as may be required; and that the remuneration for these inspections be by annual payments."

Mr. MARSHALL then moved the last resolution contained in the report: "That the inspector in medicine and the inspector in surgery, appointed as above recommended, receive for the year's services £300 and certified travelling and hotel expenses, and the inspector in midwifery £200 and certified travelling and hotel expenses."

Dr. WATSON seconded the motion.

Dr. DUNCAN asked why a difference had been made between the payment to the inspectors of medicine and surgery and the inspector of midwifery.

Mr. MARSHALL explained that the inspectors in medicine and surgery would have more work to do and more examinations to inspect than the inspector in midwifery, who would have nothing to do with clinical examinations proper.

Dr. DUNCAN said that ever since the establishment of the Council midwifery had been combined with gynæcology, and therefore involved clinical work. He moved "that the emoluments of the inspector in midwifery be the same as those of the inspectors in medicine and surgery."

Dr. HAUGHTON seconded the amendment on the ground that the Act of Parliament placed the three subjects of surgery, medicine, and midwifery on an equality.

Digitized by Google

Dr. STRUTHERS said it was estimated that the inspector in midwifery would not employ more than half the time that the others would.

The amendment was then negatived, and the motion was agreed to.

Dr. QUAIN moved, and Sir WALTER FOSTER seconded: "That it be referred to the Executive Committee to make arrangements for carrying out the resolution just adopted, and to report to the next meeting of the Council thereon."

Mr. SIMON objected to this work being thrown on the Executive Committee, and moved as an amendment "that the Inspections of Examinations Committee be continued during the pleasure of the Council, and that this committee (subject to the future directions of the Council) be charged with the duty of giving to the inspectors such instructions as may be requisite, and of superintending the progress of their work."

After some discussion the amendment was negatived and the motion agreed to.

It was then, on the motion of Mr. MARSHALL, seconded by Sir WILLIAM GULL, resolved that a record should be placed on the Minutes of the Council of the presentation to the President that took place on the previous evening, and of the acceptance of the bust by the Council.

The PRESIDENT having made a statement to the Council in reference to the communication which the Council had directed to be made to the Royal College of Physicians of London and the Royal College of Surgeons of England, and to the communication which the Council had directed to be made to the King and Queen's College of Physicians in Ireland and the Royal College of Surgeons in Ireland, and having expressed his intention to resign his office at the close of the present meeting, it was unanimously resolved: "That the President be invited to continue in office until the next meeting of the Council."

The President having consented to adopt this course, the Council adjourned.

WEDNESDAY, FEBRUARY 23RD.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

Dr. HERON WATSON drew attention to a report in the morning papers of an application before a divisional court for a rule for a writ of mandamus directed to the Council ordering them to restore the name of Mr. Partridge to the Register under the provisions of the Dentists Act of 1878. He wished to ask whether the Royal College of Surgeons of Ireland had any explanation to afford in regard to the statement that they had withdrawn Mr. Partridge's diploma on the ground that he had advertised in the course of his business as a dentist; whether the College required of each licentiate in dental surgery that he should sign a declaration before receiving his diploma that he would not advertise or employ unworthy means of attracting public notice; and, thirdly, whether the Royal College of Surgeons of England had any similar provisions against advertising.

The REGISTRAR announced that he had received a letter from the solicitor bearing upon the subject.

Strangers were then requested to withdraw, and during their absence the subject was referred to the Executive Committee.

On the public being readmitted,

Sir W. GULL moved the adoption of the report by the Lord President's Letter Committee.

The committee was appointed to consider a memorial addressed to the Lords of the Council by Mr. Thomas Laffan, of Cashel, with respect to the efficiency of qualifying examinations under the Medical Acts. Mr. Laffan charged the General Medical Council with inaction, and stated that the candidates for the degrees of the Royal University of Ireland "are shamefully deficient in clinical training"; and that the University imposed restrictions in the way of adequate clinical training. The committee considered the charge of inaction devoid of foundation. With regard to the second charge, they considered that the large proportion of rejections proved the imperfect training of the candidates no less than the impartiality and discrimination of the examiners. In reply to the third charge, the committee felt the strongest sympathy with the utilisation of the clinical material in union hospitals, but it was a matter which required inquiry into the character of each hospital, and the material it offered for affording useful clinical instruction. In conclusion, they begged to assure the Lord President that they had full confidence in the Royal University of Ireland maintaining the efficiency of its qualifying examinations under the Medical Acts, and in their adopting so far as a non-teaching university could, every possible means for promoting the practical training of students.

Dr. MOORE seconded the motion.

Mr. MACNAMARA said Mr. Laffan's grievance was really not much more than a sentimental one. Ever since he (Mr. Macnamara) had been connected with the governing body of the College of Surgeons, Ireland, there had been a rule that six summer months' attendance in a provincial hospital should count as equivalent to three summer months' attendance in a hospital in Dublin, Cork, Galway, or Belfast; but the registrar of the College could not recollect one instance for years past in which a student had availed himself of the privilege. A somewhat similar rule prevailed in the University of Dublin, and yet Dr. Haughton had told him that during the thirty years when he conducted the medical examinations there he only remembered three cases in which students sought to take advantage of it, and all those students happened to be the sons of surgeons attached to hospitals.

Dr. BANKS said that the Royal University of Ireland accepted certificates of attendance at the county infirmaries.

Dr. LEISHMAN said that the Royal University of Ireland was not a teaching, but simply and strictly an examining body, but the strictures which Mr. Laffan had passed without exception pointed to deficiencies in teaching with which the University had nothing to do.

The report was then adopted, and on the suggestion of Mr. Marshall it was decided to forward it to the Lord President, together with the first and final reports of the Visitation of Examinations Committee.

The next subject was the visitation of medical schools and hospitals.

Dr. HAUGHTON proposed the motion of which he had given notice: "That the visitation of medical schools and hospitals is a pressing question, more especially as regards their requirements and facilities for the practical study of fever and midwifery cases." He said he thought he might have been spared the agony of having his motion blocked. The position of the motion, and of that to be moved by Dr. Glover on the eighth day of the session of the Council, indicated what their fate was destined to be. He asserted, from personal knowledge of the great centres of medical education, that the regulations with regard to the practical study of fever and midwifery cases were simply disgraceful. When he himself was a student, he found that, with very few exceptions, the students never entered the fever wards. There were great centres of education where fever cases were not admitted, and, as a rule, he could prove, when the time came, that the regulations for compelling the reluctant students practically to study fever were a disgrace to the licensing bodies. The new Act compelled the Council to see that the men sent out to practise were competent to deal with fever and midwifery cases. It was, however, impossible to discuss the question at this meeting, and he was quite sure the Council would consider that his proposal, taken in connexion with the motion to be brought forward by Dr. Glover, which was somewhat wider, would be worthy of the most earnest and anxious consideration at a future period. He asked Dr. Leishman to allow him to ask the Council to postpone the question, and not to let the Council disgrace itself by blocking the motion.

Mr. MACNAMARA seconded the motion.

Dr. LEISHMAN objected very much to Dr. Haughton's use of the word "block," and especially to the interpretation attached to it. His reason for giving notice of the previous question was that at the present time not one of the subjects was ripe for discussion, still less for decision. As far as he knew, the attendance on fever was compulsory in the Royal University of Ireland, and in no other licensing body. It could not, therefore, be said, at that stage of the meeting of Council, to be a "pressing" question, seeing that so many years had elapsed, and the Council had never thought it necessary to introduce any regulations on that subject; and, further, he objected to the consideration of these subjects at this moment, because they would undoubtedly give rise to a considerable degree of discussion. He should be the last member at that table to block any

Digitized by Google

question which had for its object the improvement of midwifery. He moved the previous question.

Dr. HUMPHRY seconded the amendment.

Mr. SIMON thought the whole subject involved in the motions brought forward by Dr. Haughton and Dr. Glover should be referred to a committee to be called the "Curriculum Committee." In that way very great service would be done to the medical profession.

Dr. BANKS supported Dr. Haughton's motion. As physician to a fever hospital, he knew the extreme difficulty of getting students to attend fever cases. The Royal University was not the only body that required attendance on fever cases; the University of Dublin many years ago required such attendance, and the younger university had followed in its footsteps.

Dr. MOORE thought the final examinations as to fever were not sufficient.

Sir WILLIAM GULL strongly repudiated the idea that there could be any doubt that students were required to study disease, whether fever or any other form. He expressed his surprise that on the other side of St. George's Channel there should be gentlemen who thought that their lives were in danger because they were called to see a case of fever.

Sir DYCE DUCKWORTH pointed out that it was not possible for a student in one of the great London hospitals to see a case of typhus or scarlet fever, and it was only with very great effort that a few diligent and illustrious students could be got to go to the fever hospitals to see them. The fact remained that the great mass of London students were grossly ignorant of these fevers.

Dr. DUNCAN said it was only within the last two or three years that the fever cases had been removed by order of the Government to separate hospitals. These arrangements were new and required new arrangements on the part of the Council, and he hoped that Dr. Haughton would be able to bring forward an adequate scheme at a future meeting.

Dr. HERON WATSON was glad the matter had been taken up by the Council, and hoped that the vote that day would show that the Council considered it their duty to take in hand and carry out their regulations as to courses of study.

Mr. CARTER thought a great deal would be done in the way of supplementing any deficiencies of medical examination by the inspection of examinations which the Council was about to undertake. The only thing to make students desirous of learning any particular subject was the knowledge that questions would be asked upon that subject. With regard to his own special branch of surgery, he found that the very large proportion of students never came near his wards at all; the reason given was that they thought they were practically wasting time in learning something which did not promise to be immediately useful.

Dr. BRUCE thought the Council would be going beyond its province by passing Dr. Haughton's resolution.

After some further discussion the amendment was withdrawn.

Dr. HAUGHTON expressed his pleasure at this course being adopted, as he had felt that the "block" was an offence, though of course it had not been so intended.

Mr. SIMON then moved: "That a standing committee, to be called the Curriculum Committee, be appointed to report from time to time to the Council on questions arising under Section 18 of the Medical Act of 1858, with regard to courses of study; and, secondly, that the motions of Dr. Haughton and Dr. Glover be referred to the committee for early consideration."

Dr. HUMPHRY, in seconding the amendment, said that in his opinion study and teaching would always conform themselves to the examinations, and therefore, if the Council looked well after the latter, the former would be considerably improved.

Dr. DUNCAN thought the proposed committee supererogatory; it would merely be a department of a committee already in existence.

Dr. STRUTHERS also considered the committee unnecessary.

Dr. PETTIGREW was opposed to the amendment. The question of the visitation of schools had been referred to the Branch Councils, and it would not be treating them fairly if a general committee were appointed to supersede them.

Dr. HERON WATSON considered that if the committee were appointed, their only duty would be to constantly harrass the medical schools.

Mr. SIMON said he did not propose a visitation of schools, but only that the committee should have under their cognizance a particular class of questions.

The amendment was put and lost.

Another amendment, moved by Dr. STRUTHERS, to postpone the question until the next meeting of the Council, was carried.

Dr. GLOVER then proposed the following resolution, of which he had given notice: "That a committee be appointed to consider the best methods of increasing the practical element in medical education—as by a system of limited pupilage with a registered practitioner, and insistence on more clinical, therapeutical, and pathological teaching and work in medical schools." He said there were two or three facts which went far to justify him in bringing forward this resolution. The first was a very prevalent impression in the minds of the profession that, whatever might be the accomplishments of the men now leaving the schools, they were not well up in practical subjects, because they had not had opportunities of becoming familiar with the common diseases which made up the bulk of medical practice. He was afraid that the pecuniary difficulties of the hospitals would accentuate this state of things, and that the hospitals might more and more become receptacles for exceptional cases. This showed the necessity of supplementing the general hospitals with other means of instruction. The tables of results of Final examinations pointed in the same direction. The Royal College of Physicians of London in 1885 rejected 152 and passed 242; the Royal College of Surgeons rejected 443 and passed 561; the Apothecaries' Society rejected 121 and passed 235. In Scotland matters were still worse. The Royal Colleges of Physicians and Surgeons of Edinburgh rejected 116 and passed only 91; at the Conjoint Examination of the three corporations there were 74 rejections and 84 passes. In Ireland the Royal College of Surgeons rejected 54 and passed 81; the Royal University rejected 77 and passed 76. He could not help thinking that these figures showed a terrible deficiency in the means of practical teaching. Many of the men so rejected were men of some character, as they had passed the earlier examinations, and some of them were known to be very good men. The favourite explanation of the failures was that the students were to blame, that they had been idle or slow to learn; but such wholesale rejections seemed to require a far deeper and more thoughtful explanation. Probably it would not be far wrong to divide the blame between the candidates, the teachers, the schools, and the Medical Council, which had not made stronger recommendations as to the need of practical teaching. It was notoriously true of many of the best schools that there was a great disproportion between the clinical field provided and the number of students. There were some great opportunities for practical teaching which were not utilised. First, there was private practice. Many practitioners who had had good masters, as he had, believed in some modification of the old system of pupilage, where common diseases and common remedies became familiar to the students, and he believed that great good might be done by bringing private practitioners into co-operation with medical schools. Then there were the workhouse infirmaries, which would supply a field of enormous value, containing, as in London they did, numbers of common diseases and some which were uncommon. Some of the medical officers there were developing branches of pathology in a surprising way. There was also a great deal of midwifery in the workhouses, and the number of surgical cases was very considerable. Dr. Glover dwelt at length on the necessity for more practical teaching in midwifery. He said that many of the examining bodies contented themselves with requiring attendance on only six cases. He hoped that if the committee were appointed they would see their way to recommend the examining bodies to require such an education in midwifery as would guarantee the actual observation of the operations and complications of midwifery.

Dr. CHAMBERS seconded the motion. He said he could confirm what had been stated by Dr. Glover about the general feeling in the profession as to the incompetence of recently passed candidates. A few years ago statements were made by those who employed them that they were compelled to do

Digitized by Google

so because qualified men were not competent. He considered that the blame rested with the Medical Council in consequence of the arrangement of their curriculum. In the final examination a man was called upon to pass in subjects which he had learned in the lecture-room some time before, the intervening period being supposed to have been spent in clinical study. The consequence was that if he did study clinical medicine he got plucked in his proper work. A remedy might be found in the multiplication of examinations. A man might be allowed to pass in the principles of medicine, surgery, and midwifery, and after a certain time he might be examined in art.

Mr. WHEELHOUSE supported the motion, regarding the subject as one of extreme importance. If a committee were appointed to consider it, and bring up a report, the Council might afterwards be able to arrive at a just decision upon it.

Sir W. GULL supported the motion. Hospitals taught morbid anatomy, and pathology founded upon it; but there was a very wide area of pathology which had no morbid anatomy, and which could only be studied in private practice.

Dr. HERON WATSON explained that the number of rejections at the final examination of the Royal Colleges in Edinburgh was due to the fact that many of the men were inefficient, remaining over from the old state of affairs. Some of them had come up as often as six times, but they could never do so again. In the University of London there was a still higher percentage of rejections.

Dr. STRUTHERS suggested that the students might be connected with practitioners after they had passed.

Dr. HUMPHRY said the real difficulty in connexion with the clinical teaching was the enormous amount of preliminary work which was laid upon them.

The motion was carried unanimously, and a committee was appointed consisting of Mr. Wheelhouse, Dr. Chambers, Mr. Mitchell Banks, Dr. Haughton, Mr. B. Carter, Mr. Teale, Dr. Fergus, Dr. McVail, Sir W. Foster, and Dr. Glover.

On the motion of Dr. HERON WATSON, seconded by Mr. MARSHALL, the thanks of the Council were voted to the Directors-General of the Army and Navy Medical Departments, with a request that they would continue to supply the Council with the number of candidates referred to in their respective lists who had two or more qualifications, and the number of those who were passed or rejected.

A table prepared by the Registrar, showing the number of candidates and the rejections per cent. at final examinations in the years 1883 to 1886, was received, and entered on the Minutes.

This concluded the business of the session.

"GENESIS OF THE ELEMENTS."

THE wonderful hypothesis in regard to the evolution of chemical elements which Mr. Crookes produced at Birmingham last August, in his address as president of the Chemical Section of the British Association, was again unfolded by him the other day, in a Friday evening lecture at the Royal Institution. Some slight variations were introduced, and a number of magnificent experiments aided the audience, but substantially the hypothesis stands as it did when we presented a sketch of it in the autumn. It starts, it will be remembered, from the diagramatic, and, so to speak, symbolic expression which Professor Emerson Reynolds devised for the illustration of the periodic law of Newlands. A pendulum, with a pencil attached to its weight, is supposed to be falling slowly to rest, and at the same time to be sinking bodily downwards. The pencil would mark on a vertical sheet of paper a zigzag line of decreasing amplitude. If a perpendicular line were drawn down the middle of the paper, the zigzag line would cross it repeatedly, sometimes approaching and sometimes receding from it. This swing and simultaneous fall of the pendulum denote two opposite forces, which may be supposed to have co-operated in the genesis of elements. Imagine a uniform elementary matter, which Mr. Crookes, for convenience, calls *protyle*. This is at an enormous and unknown temperature, but at some period inconceivably remote, and before the birth, not only of suns, but of all known kinds of matter, cooling began, typified in the diagram by the gradual perpendicular fall of the pendulum. Simultaneously there comes into play some other force—perhaps electricity—which is denoted by the horizontal and gradually diminishing swing of the pendulum. Now, if the symbols of the elements are marked at regular intervals on the zigzag in the order of their atomic weights, it is seen that they fall into octaves, or series of seven. On all parts of the line receding from the perpendicular electro-positive elements occur, and their valency increases steadily. Thus, starting from hydrogen, we find lithium, glucinum, boron, and carbon as the first four. As the pendulum swings back and approaches the perpendicular, we find nitrogen, oxygen, and fluorine, and then, on the receding half, sodium, magnesium, aluminium, and silicon, the eighth from carbon. The whole diagram exhibits the periodic law with remarkable distinctness, and, apart from the use to which Mr. Crookes puts it, will have great value to teachers. Mr. Crookes suggests that by the operation of forces typified by the great cosmic pendulum the atoms have been developed from protyle at successive stages of time. Occasionally several very similar elements have been generated instead of one, so that we have the groups nickel and cobalt and the platinum metals nearly of the same atomic weight, and very similar in properties. Space precludes us from giving any adequate account of the mass of ingenious reasoning and experimental illustration which Mr. Crookes has brought to bear upon his hypothesis. Of the experimental portion, the most important and the most original is that which deals with the separation of the very similar and very scarce metals of the yttrium group. By a system of fractionation, which is a marvel of ingenuity and industry, and by the use of the amazingly delicate radiant matter test, Mr. Crookes appears to have found that seven, or perhaps nine, kinds of atoms are present in what we have always called yttrium. He has, in fact, sorted the atoms. Are these so similar, yet not identical, atoms to be taken as separate elements? or, as has before been suggested, is what we call the atomic weight only the average atomic weight—and, if we could weigh all atoms, should we find them to be only very nearly but not quite the same? Science does not as yet afford a positive answer.

THE MARGARET-STREET CONSUMPTION INFIRMARY.

THE following letter has been addressed by the undersigned members of the medical staff to the Executive Committee and governors of the infirmary:—

LORDS, LADIES, AND GENTLEMEN,—After the vote of the governors at the special general meeting on Wednesday last, which enables professed homœopaths to hold office on the medical staff, it has become necessary for the undersigned members of that staff to resign into your hands the appointments which have been held by many of them for a long series of years, under the belief that their services were appreciated and that they wee doing good and useful work for the sick poor; it is therefore with great regret that they take this step, but the action of the governors has left them no alternative. The undersigned took office in the belief that they were connecting themselves with an institution belonging to and governed by the doctrine and practice of established medical science sanctioned by the most learned professors and schools of medicine throughout the world, and which alone is held and taught by our own governing bodies, and they feel that this new departure is equivalent to an abandonment of the same, and that its acceptance would be a betrayal of honour unworthy the members of the noble profession to which they belong.

Thanking you for the confidence hitherto accorded,

We remain your obedient servants,

THOS. HAWKSLEY, M.D.
WM. CHOLMELEY, M.D.
F. CARR BEARD, F.R.C.S.
R. FEATHERSTONE PHIBBS, M.R.C.P.
JULIAN WILLIS, M.R.C.P.
ROBERT WALFORD, M.B.
SCUDAMORE K. POWELL, M.D.

Feb. 23rd, 1887.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 26, 1887.

THE General Medical Council will this week finish their sitting, and they may congratulate themselves on the quantity as well as on the excellence of the work they have accomplished. The subjects they have had under their consideration are of much moment to the profession, and they have wisely construed in a liberal sense their duties in relation to them, and have not limited themselves merely to carrying into effect their statutory powers.

The demand of the Apothecaries' Society of Dublin for the appointment of assistant examiners, which we discussed in our last number, was followed by a similar application from the London Society, and with the same result. The statement of the Society's case by Mr. BRUDENELL CARTER made it a matter of difficulty to refuse their immediate request for the appointment of assistant examiners, and effectually disposed of any probability that it would not be eventually complied with. He drew attention to the services the Society had in the past rendered to medical education, and to the rights conferred upon them by the Medical Act of last year. His plea was in no sense one *ad misericordiam*, but was a demand for justice, with which the Society is certain to meet. An amendment by Dr. STRUTHERS and Mr. TEALE was, we are glad to say, carried by a large majority, and the Council have urged upon the three London Corporations, "in the interests of the public," the desirability of combining for the purposes of holding one licensing examination. The willingness of the Apothecaries' Society to join with the other bodies was amply vindicated; the refusal has come from the Colleges alone; and the Society would still combine, although they would not be prepared again to take the initiative. Nevertheless, the effort is worth making, and the opinion the Council have formed will, we trust, meet with the respect it deserves.

What will be the result of this further opportunity for the avoidance of competing examining bodies, which is thus afforded by the action of the General Medical Council, time alone will show. But the profession will regard with satisfaction the fact that the Council have shown themselves alive to its best interests, and that, whatever the outcome of this proceeding, they have been willing to utilise every power they possess to prevent the existence of conditions which will militate against the prosperity of the profession, and which the legislation of last year was mainly enacted to prevent. In these endeavours they have been warmly seconded by their President, Sir HENRY ACLAND, who has not hesitated to place his great personal influence at their disposal, and who has freely undertaken to be the means of communicating the Council's views to the corporations in London and in Dublin, whom it is hoped to persuade. Until the final decision is known, the hope will still be entertained that the bodies may take the higher view of their duty, and may be willing to make some sacrifice in a matter which so closely concerns the welfare of the profession and the interests of the public. A journey to Ireland and the labour these communications will involve are no light undertakings for Sir HENRY ACLAND, and the profession will recollect with gratitude the efforts he has made to give effect to the resolution of the Council. His action must undoubtedly impress the corporations with the importance which the Council attach to the principle of unity, and will, we think, remind the Colleges both of London and Dublin that Mr. SIMON is not exceptional in his opinion that "in proportion as they feel themselves higher and stronger than the Society of Apothecaries they are bound to adopt the course which is recommended to them—*noblesse oblige*."

It is conduct such as this that has won for Sir HENRY ACLAND the esteem both of those who have shared his work and those who have been but the witnesses of his labours. It will therefore be a cause of general regret that he has felt the necessity of curtailing the demands upon his strength which the business of the Council incessantly makes. During the many years he has, as a member of that body, and subsequently as its President, influenced its proceedings, he has unswervingly kept before his mind the advancement of the profession with which he is associated. For this reason we fully sympathise with his colleagues in their desire to do honour to him at the close of a long and useful career. The admirable bust which they have presented to him, and which will serve in the future to remind the Council of their former President, is a marked expression of the estimation in which his services have been held by those who are best able to appraise them at their true value. Placed, through Sir HENRY ACLAND'S courtesy, in the Council chamber, it will be a permanent record of their appreciation of his worth, to which Professor HUMPHRY bore eloquent testimony. It is a source of satisfaction that Sir HENRY ACLAND has not yet absolutely severed his connexion with the Council, and that he has consented to remain for a short while in office until the important business he has undertaken is accomplished. There could be no more fitting termination to his tenure of office than this present effort to unite the corporations in a duty in which competition should be unable to find a place.

Of other important work before the Council, we must mention the presentation of the final report by the Visitation of Examinations Committee. This report is of so much consequence to the profession that we propose to discuss it at length in a future number. Some other business occupied their attention, but that of greatest interest was undoubtedly the proposals of Dr. HAUGHTON, which related to the provision of better facilities for the study of fever and midwifery cases, and of Dr. GLOVER, that a committee should be appointed to consider the best methods of increasing the practical element in medical education. Mr. SIMON made the happy suggestion that a special "curriculum" committee should be appointed to consider these resolutions, as well as the whole subject of the course of study which it was advisable should be pursued by candidates for the profession. Although the Council did not accept Mr. SIMON'S proposal in the form in which it was placed before them, they adjourned the further consideration of Dr. HAUGHTON'S motion to a future meeting, and Dr. GLOVER'S to a special committee. It is certainly true that medical students

Digitized by Google

are not required to, and do not, avail themselves of the opportunities which are afforded by special institutions for the study of infectious disease. But this is not the only subject neglected. Dr. GLOVER'S desire to amend medical education is based upon the fact that young medical men are often found wanting in knowledge of practical details when they are called upon to engage in active practice. It is not at once easy to see how this difficulty is to be overcome. The period formerly passed in a lengthened pupilage being now devoted to studies which obviously fit men eventually for undertaking higher duties, the question to be considered is whether on the whole the gain compensates the loss. There will, however, be general agreement that some effort should be made to supply deficiencies; but whether it should, as Dr. STRUTHERS and Dr. MCVAIL proposed, take the form of improved clinical teaching, or whether, as was suggested, the material in workhouse infirmaries might be utilised, or arrangements could be made with gentlemen engaged in active practice for this purpose, the Committee must consider.

OF all the complications of labour, none is more urgent and more serious than hæmorrhage; and of the causes of hæmorrhage none is more important than placenta prævia. The earliest mention of the condition is to be found in the works of GUILLEMEAU, in A.D. 1609; and next in those of MAURICHAU, A.D. 1668. Their view was that the after-birth was originally situated higher up, but became displaced as pregnancy proceeded, a view which is still extant in the phrase popular among the lower classes and midwives—"the after-birth slipped." The correct view, that the after-birth is firmly planted in its dangerous position, was first illustrated by the necropsy of a woman who died of placenta prævia, and was dissected by SCHALLER in A.D. 1709; and this view was first introduced into the text-books by JOHANN VAN HOORN, A.D. 1715, a pupil of PORTAL. VAN HOORN plainly says that the cause of the dangerous condition is the after-birth, which at the beginning of pregnancy takes its place on or above the os uteri. After LEVRET'S time the main facts with regard to placenta prævia are found generally current.

To write a historical review of the subject from that time to this would consume too much of our space; moreover, it would show occasional retrogressions in knowledge and understanding. At the present time our knowledge, which not many years ago was thought to be pretty complete, has been somewhat disturbed by the study of the "lower uterine segment," to which a great impulse was given by the suggestive studies of LUDWIG BANDL on uterine rupture, pursued by him in search of the explanation of many other problems. BANDL'S views, which need not here be given at length, were many times modified by their author, but the result of the discussion and observations which they have excited has been to show that during labour the uterine body becomes differentiated into a retracting and ever-thickening fundus, a stretching and ever-thinning "lower uterine segment," and the cervix. It is not yet, however, finally settled what is cervix and what is "lower uterine segment." The lowest part of the retracted fundus is felt after labour as the bottom of the hard uterine cricket-ball; below it come the cervix and "lower uterine segment," hanging loose, apparently unretracted and passive, like a piece of flabby hose. The question is not yet settled why, if this lower uterine segment is the site of placenta prævia, *any* woman escapes flooding to death after this complication. Meanwhile it is possible that, though it feels flabby, it may be physiologically retracted to an extent sufficient to control hæmorrhage. Having said thus much, we will proceed to be more dogmatic.

And first we would say that the utterances of the text-books on this great subject are most unsatisfactory, being overloaded with detail both as to pathology and treatment, and generally "hedging" each statement with a timidity and uncertainty which appears in the answers of students in examination, and in the treatment of practitioners. It would be worth all the writing which occupies so many pages, and leaves us at the end as uncertain as to the author's views as we were, at the beginning, to enunciate a few great propositions, and to get them well absorbed by those whom we have to teach. We will give some of them.

1. The bleeding comes from the placental site.
2. The cause of the bleeding is the detachment of the placenta.
3. The cause of the detachment of the placenta is the expansion of the lower uterine segment, which the placenta is unable to follow.

This will be seen to be equivalent to saying that before labour there is no bleeding. This is generally, but not always, true. We are obliged, therefore, to remark that the beginning of labour is not always synchronous with the beginning of the "first stage" of labour, but begins with the dilatation of the os internum, which may precede the "first stage" by days or even weeks. Also that the bleeding in placenta prævia is often due to the same causes as operate in "accidental hæmorrhage," acting, indeed, with additional advantage on account of the low site of the placenta and the consequently heavier column of blood which the utero-placental vessels have to support under these conditions.

Having plainly stated the main great facts, which are worth all the rest put together, and which should be always taught dogmatically and almost like aphorisms, we now proceed to the question of treatment, for a plain statement of which the student looks in vain in even the most recent text-books, and which seems to us capable of at least an attempt at formulation. We would first remark that a certain number of cases of placenta prævia progress favourably to a safe termination, and require no interference. This is of course more likely when only part of the placenta is situated on the area of necessary detachment, but it is not unknown where the placenta is central—that is, implanted across the os internum. In such cases the child has been known to be born by strong contractions, wearing the placenta like a cap on its head. On this the well-known treatment of SIMPSON—the complete detachment of the placenta by the hand,—and its modification by BARNES—partial detachment,—were founded. It is to be remarked that SIMPSON'S treatment was founded on an interpretation of the phenomena which implied that the woman was delivered safely because the placenta was detached, whereas in our opinion such cases only show

Digitized by Google

that the uterus acted with unusual vigour, shortening the dangerous period and producing good retraction, which, as is well known, is the only safeguard against bleeding. Detachment of the placenta apart from vigorous uterine action is only an increased element of danger. But most cases of placenta prævia do require prompt and wise interference, and to wait for their spontaneous termination would be as wrong as to wait for some form of spontaneous expulsion or evolution in a cross-birth. Treatment, to be rational, must be founded on the pathology and natural history of diseases; in other words, it must take cognisance of the causes of death with a view to avoiding them, and of the manner in which Nature deals with them when she does so successfully. We come, therefore, to enunciate two more great principles.

4. The great dangers of placenta prævia are: (*a*) bleeding before and during labour; (*b*) bleeding after delivery; (*c*) septic processes.

5. The great safeguard against bleeding before, during, and after delivery is uterine retraction.

We come, therefore, to consider how the dangers arise, how they may be avoided, and how retraction may be secured.

The cause of bleeding before and during delivery has already been touched on. It is detachment of the placenta by dilatation of the placental site. The causes of bleeding after delivery are mainly two—imperfect retraction, and laceration of the cervix and lower uterine segment, which is of course unusually vascular. This also predisposes to sepsis. The causes of sepsis are three—the low situation of the placental site, bringing it nearer to the outer world and nearer to the accoucheur's fingers, lacerations, and perhaps also imperfect retraction of the lower uterine segment. The great object, therefore, with a view to avoiding and controlling hæmorrhage, has been to produce uterine contraction and retraction; and to do this directions have been given to empty the uterus as soon as possible. The condition of the cervix, which, though soft, is often loth to dilate (probably in connexion with the abnormal position of the placenta, which disorders the polarity), has rendered it impossible in many cases to affect this without forced delivery (*accouchement forcé*), which consists in thrusting in the hand and dragging out the fœtus by the feet. This is a most dangerous proceeding, and generally takes the practitioner out of the frying-pan of ante-partum hæmorrhage into the fire of laceration, post-partum hæmorrhage, and blood-poisoning.

Delivery by the head is not suitable for cases of dangerous placenta prævia. No aid can be given till the labour is so far advanced as to be practically over so far as the danger of bleeding is concerned. A sixth proposition may now be enunciated:—

6. The great treatment for placenta prævia is turning by the feet.

Our readers will perhaps say, "and extraction." But here we must make another statement—namely, that this is usually unnecessary.

7. It is found practically that as soon as turning has been effected and the leg brought down the bleeding ceases.

The explanation usually given for this is that the presenting part plugs the bleeding site; but it is not certain whether this explanation is correct, or whether the arrest of bleeding is not rather due to the retraction which partial emptying of the uterus effects. It follows, therefore, that—

8. After the leg is brought down, the case may generally be left to nature.

THE *Saturday Review* has favoured the medical profession with some very flattering remarks *à propos* of Sir HENRY ACLAND'S address at the Medical Council. We are rising in knowledge and capacity, both socially and politically. Our social advancement is evidenced by the surprising increase that has taken place in the number of medical men who have been commissioned as county magistrates, and even sent to Parliament, that Valhalla of respectability, during recent years. Our political enlargement and ennoblement is partly indicated by, and partly due to, the fact that while the landlord and his agent and the county parson are losing ground, "the county franchise has placed 'the doctor' in more immediate contact with the great mass of voters, and brought them more immediately within the sphere of his daily influence." We confess that it is not easy to realise the force of this reasoning; but let that pass. It is at least something to our credit that we did not conspire with the *prolétariat* when both ourselves and the people were out in the cold together. It is perhaps a little humiliating to find that one of the best grounds of hope in our political future is, according to our contemporary, to be found in the fact that, while we are as benevolent as the squire and the parson, we have no land, and are not involved in questions of property which would place us at a disadvantage or breed ill-feeling between us and the voters. This is a left-handed kind of compliment, but we may endure it patiently—the more patiently, perhaps, because it is coupled with the avowal that the classes we are supposed to have displaced are a little afraid of us. "The country doctor has come into the possession of a power—what will he do with it?" is the burden of the *Saturday Review's* lament. "The profession as a whole is strongly conservative, although, as is usual with all other professions, some of its most active and conspicuous members have strong tendencies the other way. In political matters," continues our contemporary, "it is not necessary that medical men should act in one body, *as there is some fear of their doing*, but each man should identify himself with the local organisations, and thus exert his individual influence for the general good of the country and of his own locality." The terror of "the classes" is, then, that the medical profession will constitute a political organisation of itself. We hasten to assure the *Saturday Review* that there is not the least peril of such a calamity. Medical men are quite as individual in their opinions and tastes, privately and politically, as the persons engaged in other callings. We fail to perceive the slightest fear of any abuse of power arising out of the fact that a few members of our profession have been placed on the Commission of the Peace, and here and there a medical man has secured a seat in the House of Commons. We do not admit that it would be a *very* terrible evil, in a social sense, if even a larger number of practitioners of medicine had achieved socio-political greatness, but looking to the extreme paucity of the list of medical men who write M.P. or J.P. after their names, nothing but needless timidity can give rise to the fear of

Digitized by Google

a medical confederacy exerting influences injurious to the best interests of the community. Our contemporary may dismiss this cause of anxiety in so far as it can be rationally held to have any real existence. That something may have been gained in politico-social prestige by the medical profession as a body during the last fifty years is indeed possible, but the reflection can scarcely have been suggested by Sir HENRY ACLAND'S address, for the President of the Medical Council is of opinion that the internal struggles, not to say wranglings, of medical men in connexion with the development of the work of education have not tended to advance the interests of that body either socially or politically, but, on the contrary, that there has been "some loss of character to our profession." We fear the President is nearer the truth than the *Saturday Review*. In fact, we are in nowise puffed up with pride at our present position, and we do not think the profession is *in excelsis*. There is much—very much—to be accomplished before a body of men so well qualified to play an important part in the business of government and to advance the best interests of the nation, as the medical profession undoubtedly is, can properly assert and make good its really strong claims to public recognition. Had there not been extraordinary, and, as it would appear, inexplicable blundering in our policy, we should long ago have writ the maxim *Salus populi suprema lex*, which the *Saturday Review* adopts as the text of the remarkable article to which we are alluding, so large on the annals of our country that no question could possibly be held to exist as to the adequate recognition of the profession by which *salus populi* is chiefly promoted. There is, in truth, something astounding in the neglect and contumacy with which medical opinion is treated by statesmen in this country. The affectation of superiority on the part of the commercial sections of the community, tolerated by the common sense of the people, is one of the most convincing proofs that we, of England, have as yet no solid ground for the pretension to a front place in the intelligence of nations. In no other of the more enlightened nationalities are medical men so lightly esteemed or so grudgingly recognised as a power in the State as in our own country, the felicitations of the *Saturday Review* notwithstanding.

Annotations.

"Ne quid nimis."

THE FELLOWS AND MEMBERS OF THE COLLEGE OF SURGEONS.

It will be remembered that at the general meeting of the Fellows and Members of the Royal College of Surgeons in November last, the following resolutions were carried by overwhelming majorities:—1. That in the opinion of this meeting it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education—(i.) if Members of the College were empowered to take part (separately or conjointly with the Fellows) in the election of members of the Council; (ii.) if Members of the College were eligible to sit in the Council, provided (*a*) that no Member of the College shall be entitled to vote till he have been such Member for a period of ten years; (*b*) that no Member of the College shall be eligible to sit in the Council till he have been such Member for a period of twenty years; and (*c*) that not more than one-fourth of the Council shall consist of Members of the College who are not also Fellows. 2. That, with a view to give effect to the recommendations in the foregoing resolution, the Council is hereby respectfully requested to empower certain members of its body to meet and confer with representatives of the Association of Fellows and of the Association of Members, together with, if necessary, an equal number of Fellows and Members who may not belong to either of the associations, to be selected in any manner satisfactory to the Council. The Council of the College, at a meeting in January of this year, appears to have taken these two resolutions into consideration with the result that the following motion was carried: "That, although the Council is not prepared to give effect to the recommendation contained in the first resolution carried at the meeting of the Fellows and Members held at the College on Nov. 4th, 1886, the Council is prepared to act upon the second resolution, so far as to appoint a small committee to confer on the subjects of the first resolution with representatives appointed by the Association of Fellows and the Association of Members." We now hear that a joint meeting of delegates from the two Associations has been held to consider this resolution of the Council, and that they have unanimously passed the following resolution:—

"That considering that the Council has laid down as a condition of a conference that it is not prepared to give effect to the recommendation contained in the first resolution carried at the meeting of Fellows and Members held at the College on Nov. 4th, 1886, no useful purpose is likely to be served by a conference on these subjects with representatives of the Associations of Fellows and of Members; but if the Council will withdraw this condition, both Associations will be happy to appoint delegates to meet a committee of the Council."

This resolution was forwarded to the College of Surgeons, and will, we understand, be brought before the Council at its next meeting on March 10th. The Council of the College must have strangely misunderstood the significance of the resolutions of the Fellows and Members, or it would scarcely have passed the resolution we have just referred to. For, on the face of it, a conference with delegates from the two Associations could be of no use, seeing that the Council has already agreed *not to accept* the recommendations made to it. After having heard the questions fully discussed in public meeting, a few delegates from the two Associations could hardly have added anything new or weighty to the arguments already advanced, and hence no good could possibly have resulted from a conference *after* the Council had decided not to move in the direction asked for by the general meeting. The Associations have very properly declined such a meeting, and matters, we presume, must now take their course. The petition of the Members now contains nearly 5000 signatures; the sooner it is presented the better its chance of being favourably considered.

PAROXYSMAL HÆMOGLOBINURIA IN SWEDEN.

DR. R. BRUZELIUS, writing in the *Nordiskt Medicinskt Arkiv* on paroxysmal hæmoglobinuria, gives an account of the only three cases he has seen in the course of a long period of practice. These are the only ones which have been published by a Swedish practitioner, and in Norway only two cases have been reported. Of all countries, England, he remarks, appears to have produced the greatest number of instances of this affection. The first case is that of a woman who, at the age of twenty-seven, after exposure to cold, experienced slight rigors, pain in the sacral region, pruritus, and urticaria. These attacks returned the next four years, and then there occurred a very marked attack, with a rigor, urticaria, jaundice, and hæmoglobinuria. Subsequently

Digitized by Google

similar attacks were noted, the severity of which appeared to be directly proportional to the amount of exposure to cold which caused them. The patient was peculiarly sensitive to cold—e.g., the contact of the hand with the cold window for a few minutes brought out urticaria, with pricking and itching sensations. During the attacks there were marked crises, with rigors, pyrexia (39·5° C.), sweats, pain in the sacral region, urticaria, jaundice, and highly coloured urine containing hæmoglobin, casts, and albumen, but no red corpuscles. At the end of from three to eight hours the fever disappeared, the urine regaining gradually its normal characters. There were also other attacks of a milder nature. The microscopic examination of the blood during the attacks failed to discover any evidence of the destruction of the red blood-corpuscles, while the spectroscope revealed the presence of hæmoglobin in the plasma. Twelve years after the first attack the author saw the patient again. She had not had any marked attack during the previous three years, having carefully avoided all exposure to cold. The second case was that of a man aged fifty-two, who five years previously had been seized with an attack of hæmoglobinuria after exposure to cold air, and who subsequently always suffered from similar attacks on any exposure. No treatment proved of any avail. The man died ultimately of disease of the heart. No signs of syphilis could be detected. The third case was that of a man aged seventy-one, who had had this disease for two years. He died of acute pneumonia. Dr. Bruzelius considers paroxysmal hæmoglobinuria to be a blood disease, the destruction of the corpuscles taking place in the organs of circulation, and not only in the kidneys, as was supposed by Rosenbach. In each case the immediate cause of the hæmoglobinuria was refrigeration of the body. Other observers have, however, reported fatigue as the cause. Murri and Schumacher look upon syphilis as the real cause of the disease, but in only one of the present cases was there any sign of syphilis.

UNIVERSITY COLLEGE AND A TEACHING UNIVERSITY FOR LONDON.

THE annual general meeting of the members of University College, held on the 23rd inst., was rendered especially important by the adoption of the resolution passed by the Council, or governing body, of University College in favour of "the organisation of a Teaching University in and for London, with Faculties of Arts, Sciences, Medicine, and Laws," and the defeat of the recent resolution of the Senate, or professorial staff, in approval of an "application for the grant of a Charter to an academical body, of which University College should be the first constituent, such Charter to give the right of conferring degrees in Arts and Science only." Professor Lankester has strongly urged the adoption of the latter course, by common agreement with King's College, if the authorities of that institution so desire, and the precedent of Victoria University is in its favour, but his colleagues are obviously more desirous of obtaining the wider opportunities afforded on the basis originally laid down by Sir George Young's organisation. We fear lest the scheme may lose in intensity and cohesion whatever it may gain in other respects, by throwing the net so wide. It seems to us that a conjunction of the Arts and Science Faculties of King's and University Colleges (reserving power for the after-admission of other bodies and colleges) might have formed a combination with the Royal Colleges of Physicians and Surgeons as a Medical Faculty, which would have served as an admirable basis for a true academical university. For some such plan very strong support from without as well as from within the profession would have been forthcoming, and legal difficulties which might hinder the obtaining of a Charter for the two Royal Colleges only for granting medical degrees would easily have been overcome. A greater difficulty will probably be experienced in a combination between the Royal Colleges and the Executive Committee of a Teaching University, which has no real existence except in the Faculties of King's and University Colleges, than by the more direct and simple plan. The Royal Colleges are not likely to yield the control of medical teaching and medical examinations to a third body, over which they will only be able to exercise an indirect and a limited authority, and this will be the great obstacle to Sir G. Young's scheme, and far outweigh the considerations involved in the hostility of the University of London towards the more definite proposition. The Council of Legal Education has shown no desire to be approached by a body desirous of giving degrees in Laws; and we can scarcely expect the Colleges of Physicians and Surgeons to look more kindly on it when proposing to control the conditions for the conferring of degrees in Medicine. Some compromise must be arrived at by the executives of the two organisations, and the Crown will look more favourably on a united application for power to confer degrees in all Faculties than on two separate, and to some extent antagonistic, proposals—one in all Faculties, and the other only in Medicine.

PROFESSOR VIRCHOW ON MYXŒDEMA.

IT is a curious and interesting fact that the condition with which we have been familiar in this country for the past ten years under the name "myxœdema" is almost unknown in Germany, the home of scientific medicine. The clinical characters of the condition are so obvious that it was a matter of some surprise when Dr. Ord first formulated them (following, it will be remembered, Sir W. Gull's observations on the "Cretinoid State in Women") that the cases should have been overlooked. To German physicians the present state of ignorance is the more significant, as it indicates a lack of knowledge of English literature, which is hardly reciprocated. In France the subject has been more studied, and M. Charcot some years ago suggested the alternative title of "cachexie pachydermique" as descriptive of it. Professor Virchow has, therefore, done a real service in introducing the subject of myxœdema to the Medical Society of Berlin, of which he is President (see *Berl. Klin. Woch.*, 1887, No. 8). He said that although the London Clinical Society had collected details of 110 cases, and many had been published in France, there were records in Germany of but two or three cases, and these of quite recent date. In his visit to London last October he enjoyed opportunities, especially at St. Thomas's Hospital and the Brown Institution, of becoming familiar with the disease; and his address was largely taken up with the interesting subject of its pathology as investigated by Professor Horsley. He had been convinced from inspection of Professor Horsley's preparations of the truth of his statement that lymphoid tissue occurs in the thyroid body; but, although accepting the fact that the blood in the thyroid veins is 7 per cent. richer in leucocytes than that in the corresponding arteries, he hinted that this difference may be explained by the slower current in the veins, and did not consider the lymphoid tissue to be adequate to entitle the organ to be considered of hæmopoietic nature. As to the nature of a myxœdema, he pointed out that adipose tissue, when atrophying, undergoes mucoid change—a reversion to the fœtal state; but that myxœdema is not a mere atrophic change. On the other hand, it is the outcome of an active process of cell growth in the cutaneous and subcutaneous connective tissue, with increased bulk, whilst the superficial layers of the cutis

Digitized by Google

are not involved. It resembles an inflammatory rather than an active process, and he was reminded of the similarity to the condition of phlegmasia alba dolens, or pachydermia. The experimental and chemical researches of Horsley and Haliburton, which prove that extirpation of the thyroid is followed by an increase of mucin in the blood, tissues, and secretions—a condition of "myxœmia"—form a distinct advance in the knowledge of the subject; but Professor Virchow expressed himself with caution upon the theory of the function of the thyroid propounded by Horsley upon these results. Nor does the histology of myxœdema bear out the notion of its being mainly a condition due to retention of mucin; on the contrary, it points to an active irritative process. Professor Virchow next passed to consider the relations between myxœdema and cretinism, and again cited Professor Horsley's experiments on monkeys, which in a few weeks after thyroidectomy passed through a series of stages — neurotic, mucinoid and atrophic — to death; and where, after exclusion of any nerve lesion, the phenomena were attributed to perverted nutritional changes. He called to mind the ill effects, noted long ago, of the too rapid wasting of the thyroid under treatment of goitre by iodine—effects attributed by some to iodism, but considered by Virchow himself (*Geschwülste*, i., 114) to be due to the "goitrous cachexia." He discussed the association between goitre and cretinism, and between so-called "congenital rickets" and cretinism, with especial reference to myxœdema, adducing some interesting facts, such as that of two infants, subjects of "congenital rickets": one presented the characters of myxœdema, and had an abnormally large thyroid; the other was small and atrophied, having no myxœdematous characters, but having extreme atrophy of the thyroid, such as described by Ord in myxœdema. He also referred to Küster's observation upon "cachexia strumipriva," and glanced at the subject of exophthalmic goitre, more by way of contrast than as illustrating any relationship between Graves' disease and myxœdema; and he concluded by admitting that although the part played by the thyroid body in myxœdema was not yet proved, it was a subject worthy of careful study. Professor Ewald, who spoke on the conclusion of Professor Virchow's paper, preferred "cachexia pachydermica" to the term "myxœdema," and suggested that in Horsley's experiments the increase of mucus in the salivary secretion was attributable to injury to the sympathetic during the operation of extirpation of the thyroid. He mentioned that recently Schiff and Herzen had observed spasmodic affections suggestive of cortical irritation to follow extirpation of the thyroid, whilst Albertoni and Tizzoni had noticed a great diminution in the blood-capacity for oxygen; and he considered that such varied results proved how far we are from a knowledge of the functions of the thyroid. Drs. Wolff and Bergmann also spoke, their remarks being mainly directed to the effect of partial thyroidectomy in producing atrophy of the remainder of the body—a result which does not obtain in experiments on the healthy organ.

THE ASYLUM-BUILDING MANIA IN SCOTLAND.

IT is said of the Scotch that they have a keen eye to economy. No one would think so to observe the growing passion for huge asylums north of the Tweed, if it were not a recognised fact that asylum-building is distinctly a mania. If it were not so, a clear-headed and far-sighted people would never be so infatuated as to squander many hundreds of thousands of pounds every year, as we do, in seeking refuges for the insane, instead of providing hospitals of moderate size for their rapid cure. It is not too much to say that fully one-half of the lunacy in the United Kingdom is really factitious. Our laws and our asylum system directly tend to the cultivation of mental disease in its chronic forms. The obstacles which the law—in its benevolent imbecility—throws in the way of prompt treatment, and the practice of herding the insane in vast caravanserai, and treating them in classes instead of individually, combine to render rapid recovery improbable. There can be no radical change in these respects until fine lesions of the brain are, like coarse lesions, held to constitute ordinary disease. It is the separation of physical disease with mind (i.e., brain) symptoms from physical disease without what are arbitrarily called mental phenomena—albeit there may be delirium, and impulsive or even delusional excitement—that creates the anomaly and entails all the mischief and failure. We heartily sympathise with ratepayers groaning under the influence of "further lunatic asylum accommodation," and only wish they had the courage to put a stop to it.

EXTIRPATION OF THE SPLEEN.

AT the recent congress of Russian medical practitioners, Dr. A. G. Podrez, privat-docent in Kharkoff, read a paper on extirpation of the spleen, including the notes of a case in which he himself had recently performed this operation. The patient was a woman with ague-cake, associated with ascites and extreme cachexia. The operation was performed on the 22nd of November last; the patient subsequently went on well, being able to get up on Dec. 10th. The weight increased and the ascites disappeared. On the 16th, however, she had a rigor, and the urine contained a large quantity of albumen and hyaline casts. Death occurred on the 27th, and was due, as shown by the necropsy, to diffuse parenchymatous nephritis. The total number of cases of extirpation of the spleen collected by Dr. Podrez (including his own) is forty-two. Of these one was performed in 1549 by Saccharelli, and one in 1711. The rest all belong to the present century. If his own case is reckoned as a recovery, the mortality is 73 per cent.; if otherwise, the mortality is 76; the recoveries being twelve or eleven out of the forty-two cases, according as this is or is not reckoned as belonging to that category. The cause of the eleven deaths was septicæmia in one case, peritonitis in one case, and hæmorrhage either during or shortly after the operation in all the others. Dr. Podrez thinks that an improved method of performing the operation is required in order to obviate the tendency to hæmorrhage. It is also to be desired that, by means of further observations, the indications for the operation in cases of enlarged spleen associated with both ague and leukæmia may be defined.

SANITARY SCIENCE.

IN a lecture on Sanitary Science with which Dr. Edward Seaton recently inaugurated his lectures on Public Health at St. Thomas's Hospital, the point was insisted on that the advocacy of cleanliness was not the sole object of sanitary workers. The enforcement of cleanliness has undoubtedly done much to improve the public health, but there is too much tendency at the present time to forget that for the prevention of disease much more is necessary. Our knowledge of its causes is still in its infancy, and until these causes are fully understood it is impossible to define the means by which it shall be prevented. To rely upon cleanliness alone is, therefore, to neglect other conditions which are often far more potent for evil. Dr. Seaton's protest is certainly timely. We freely join with him in the desire to see the doctrine of cleanliness generally accepted, but we none the less accept his view that this is not a panacea for all human ills. Every year emphasises this opinion, and teaches us that many maladies, and especially some of those which are of a communicable character, have less to do with filth as a cause than was formerly supposed.

Digitized by Google

The recent investigations of Mr. W. H. Power have shown this forcibly, and lead us to hope that sanitary science has before it much greater triumphs than those which have already been attained. It is not many years ago that the public were taught that all that could be known was already discovered, and that the use of a two-foot rule was now all that was required for the purposes of sanitary administration. It is this view which the public is but too willing to accept; its teachers are not always those who are workers, and it is well that it should be reminded from time to time that sanitary science must necessarily be progressive. We trust Dr. Seaton's protest will be heard outside his class.

THE ROYAL ASYLUM OF ST. ANNE'S SOCIETY.

IN the year 1702, the first year of the reign of Queen Anne, a few benevolent persons, amongst whom were the excellent and pious Dr. Bray and Mr. R. Nelson, formed themselves into a society for clothing and educating twelve boys, the sons of parents reduced to a necessitous condition. In 1790 the St. Anne's Society established a girl's school in connexion with the town establishment. The good work has prospered, and the Society has enlarged its sphere of usefulness and benevolence, so that now the establishment consists of a governess and master, thirty boys, and thirty girls. Besides this town school, which is open to children living within two miles of its building, there is a country asylum, and lately some new schools have been erected at Redhill for the accommodation of 400 children. The institution has special claims on the medical profession, for many of the benefited are the children of medical men. The same kind and generous friend who has already founded three perpetual presentations to this institution for the orphan daughters of distressed medical practitioners has this year added a fourth, and this presentation, like the others, is in the hands of the Royal Medical Benevolent College. The annual festival was held on Tuesday last, and the report of the Committee showed that excellent management prevails, for the institution pays its way, though it is unendowed and without any permanent income. The secretary is Mr. R. H. Evans, and the offices are situated at 58, Gracechurch-street, where donations may be sent.

THE CONTAGIOUS DISEASES ACTS IN QUEENSLAND.

ON Oct. 1st, 1886, a motion for the repeal of the Contagious Diseases Acts in Queensland, which was one of the first of the British dependencies to follow England's example in passing them, was moved in the Parliament held in Brisbane. It was only carried by the casting vote of the Speaker, in a thinly-attended House, there being but thirty-one members present. In consequence of this the Premier of Queensland has wisely, as we think, decided not to act on it, especially as many members were absent who would have opposed the motion. The next session will commence in June, when the subject will again be brought forward. From the report of the proceedings in the official "Parliamentary Debates" it would appear that the opponents raised all the old stale objections, but fortunately those who supported the Acts were fortified with replies to them in the series of articles which were recently published in THE LANCET, enabling the Premier and those who agreed with him to refute completely every one of these objections. It would indeed be unwise were Queensland to repeat the mistake of the mother country, more especially in view of the experience of other colonies. Only last week it was noticed in our columns that the authorities of two of the districts in the southern counties formerly protected by the Acts were about to appoint a deputation to wait upon the Local Government Board with the view of urging upon the President the restoration of the Acts. Reports from all the other districts show that the repeal of the Acts has proved disastrous in the extreme. It has been found necessary to reinforce them in and around the vicinity of Cape Town, in consequence of the fearful spread of venereal diseases, and notably of severe forms of syphilis among both the native and European population. A like result followed the repeal of similar Acts in Malta, Bombay, and other colonial places, and judging from what has been effected by the Acts in Queensland, it is very clear that their repeal would be a retrograde step to be much regretted subsequently. All the arguments were as usual in favour of the Acts; the case of the opposite side was not argument, but sentiment of the weakest character. The question, after all, is—Are common prostitutes in Queensland or elsewhere to be permitted to spread these diseases broadcast without let or hindrance? Those who would answer in the affirmative cannot justify themselves as humanitarians, either to the unfortunate women themselves or to their victims, who, as has been repeatedly shown, are not only vicious men, but innocent wives and children. Those who, on the other hand, would wish to prevent the spread of these loathsome diseases will find no better means of doing so than the Acts of 1866 and 1869, which, so far from being specimens of hasty legislation, as has been so recklessly asserted, give evidence of such care in their framing as to be scarcely capable of improvement.

THE INTERNATIONAL MEDICAL CONGRESS.

WE hear on the best authority that several of the Transatlantic steamboat companies are prepared to make considerable reductions in their fares to medical men attending the International Medical Congress to be held at Washington in September next. The Hamburg American Steamship Company offers a first-class return ticket for £18, whilst the Royal Netherland will provide similar accommodation for £16. The Red Star line will give a return ticket from Antwerp to New York for £20. The Inman line, whose steamers are among the largest and fastest on the Atlantic, will also afford every accommodation to passengers at reduced fares; but the Cunard have declined to entertain the overtures which have been made to them. Ladies accompanied by members will also be taken on favourable terms. The hotel expenses, everything included, need not exceed from twelve to sixteen shillings a day: so that it will be possible for members of the Congress to attend the meeting for about twenty-five guineas a head. Messrs. Thos. Cook and Son, of Ludgate-circus, and 261, Broadway, New York, have issued a circular of round tours through the United States, at fares which are extremely moderate.

WOMEN DENTISTS.

THE Committee of the National Dental Hospital have resolved to admit registered female medical students to the practice of the hospital; moreover, we find upon looking through the Dental Register which is issued by the Medical Council the names of twenty-two women, sixteen of whom are practising in England, two in Scotland, and four in the colonies. All these are registered on the ground of being in practice before the passing of the Dentists Act. The College of Surgeons of Edinburgh have also decided to admit women to the examination for the licence in Dental Surgery, but we believe so far none have applied. The question arises—are women fit to be dentists? A great deal has been written and said recently about the ill effects of those occupations for women which necessitate long-continued standing, and how much worse must it be when to the standing is added the strained and cramped position

Digitized by Google

necessitated in stopping, which takes up the greatest part of the time of the dentist of the present day. That the long-continued confined position is a severe strain is shown by the occasional occurrence of neuralgia of the anterior crural or external cutaneous nerves of the leg, which is known by the name of "the dentist's leg." We think that women must often fail in extracting teeth from sheer want of muscular power. Again, in mechanical ideas women are particularly wanting, a fact perhaps due to their training, but nevertheless a fact; and in what department of dentistry does not mechanics play a large part?

WEST DERBY INFECTIOUS HOSPITAL.

THE West Derby Local Board of Health find themselves confronted with a good deal of opposition in their efforts to provide their district with a hospital for the isolation of first attacks from infectious diseases. The difficulty as to site is one that has to be faced nearly everywhere, for such hospitals and similar institutions are never regarded as desirable neighbours. The last phase of the proceedings in West Derby is, however, an unfortunate one, for a body of the ratepayers demand that, instead of having a hospital in their own district, they should send all their cases to the Bootle Hospital. Such a plan is by no means a good one. The principal object which a sanitary authority should hold in view is to secure the earliest possible isolation, and since many people who would willingly enter a hospital in their own district naturally object to be sent off into another for the protection of their neighbours, it is as a rule to be desired that urban districts should possess their own hospitals. This view seems to have been enforced by Dr. Glazebrook at a recent meeting, but some of his remarks were not received with the attention they deserved.

ON RENAL SECRETION IN THE FŒTUS AND THE FORMATION OF LIQUOR AMNII.

KRUKENBERG (*Arch. f. Gyn.*, xxvi., p. 258) reviews the recent contributions to this subject, and defends his own opinion that no constant or considerable activity of the kidneys exists during fœtal life. Wiener, who takes an opposite view, bases his opinion on experiments made by injecting various substances. In one case he injected sulphindigotate of soda under the skin of a fœtus, and found the uriniferous tubules of an intensely blue colour, blue urine being present in the fœtal bladder. Cohnstein and Zuntz, on the other hand, have shown that in fœtal sheep the arterial pressure is scarcely half of what it is post partum, so that the conditions of the circulation are unfavourable to renal activity. Krukenberg replies to Wiener's arguments by pointing out that no conclusion as to physiological processes can be drawn from any experiments by which the fœtus is placed under abnormal conditions, as it is when substances such as sulphindigotate of soda are injected. Krukenberg then proceeds to discuss the question how potassium iodide or other soluble substances pass into the liquor amnii. His earlier view was that at the end of pregnancy iodide of potassium passed through the fœtal membranes into the liquor amnii, and this view was in harmony with the fact that the salt was absent from all the organs of the fœtus except the stomach, into which it could have passed by being swallowed. In his recent experiments, however, he found that the contents of the stomach might give the iodine reaction even when the liquor amnii did not—a result which appeared opposed to his former belief, and suggested the possibility of its passing from the fœtus (through the cord or placenta) into the liquor amnii. But on making further experiments he thinks his original view the most probable, while modifying it to the extent of believing that it is only towards the end of gestation that the iodide passes into the liquor amnii—i.e., at a time when the membranes become permeable. This view is greatly strengthened by comparative experiments made on guinea-pigs and rabbits. He chose these animals owing to the great difference in the thickness of their fœtal membranes, and found that when thick the iodide did not pass into the liquor amnii, while it did so when the membranes were thin. Similar results were obtained from experiments on dogs and cats. Krukenberg was further led to the discovery that amongst the fœtal membranes the ectodermic layers are those that offer most obstruction to iodide of potassium transuding into the liquor amnii, and that it is only towards the end of gestation, when those ectodermic layers become thin, that the salt can pass. His former view—that it passes through the fœtal membranes—is therefore confirmed. The experiments above referred to were made on lower animals, but there is every ground for believing the results to be applicable to man.

THE ETIOLOGY OF FOGS.

MR. JOHN AITKEN'S theory of fogs is gaining credence, and it is certainly one that has much to recommend it. There can be no question that it covers the ground better than any other. As our readers are aware, Mr. Aitken attributes the production of mists, fogs, and rain to the presence of particles of solid matter in the atmosphere. Professor Tyndall was the first to demonstrate how the atmosphere could be filtered, and to show it in a comparatively pure state. Mr. Aitken is of opinion that water vapour clings to and condenses on these particles, either bringing them down as rain, or remaining suspended with them as mist or fog. Chloride of sodium derived from the sea is the most extensive fog producer, but sulphur is the common base of town fogs; and he suggests that it is well that it should be so, because the sulphur has an antiseptic effect on the stagnant air, and saves us from worse evils than fog. This is good news to the sufferers from an annoyance which, if the theory broached be true, cannot possibly be got rid of. There is no special cause of uneasiness as to the sulphur fogs, and, on the whole, they are blessings in thick disguise. We may therefore go on throwing our three hundred and forty-seven tons of sulphur in the air every winter's day in London, not only with impunity, but with something of a sanitary pride in the achievement, because if we did not thus disinfect the stagnant atmosphere matters might be worse with us than they are at present. All the same, if we strained our smoke a little so as to get rid of the dirty carbon, it would be more cleanly, and altogether better for us.

MEDICAL ADVICE THROUGH NEWSPAPERS.

THERE is a growing tendency to the use of newspapers—not religious newspapers only—as media for giving prescriptions and medical advice to the public. Thus, in a letter in the *Weekly Times and Echo*, Mr. T. R. Allinson, L.R.C.P. Edin., "Medical (*sic*) Editor of the *Weekly Times and Echo*," thanks those who have written words of cheer, &c. He is glad to know that he has been of great service in bringing before his readers means whereby they have attained good health. Many have desired to see the worthy licentiate, because they have tried the ordinary drug doctor and have often been worse for their pains. He only asks his readers to help him by circulating the *Weekly Times and Echo*. He tells his readers his hours for consultation. But this is only benevolently to save his time and theirs. In a similar spirit, no doubt, he proposes to educate the people, and the doctors will either have to follow or—lose their incomes! We see indications of the same tendency even in quarters where we should have expected better things. For instance,

Digitized by Google

just now in the case of Ealing, where the public has been agitated with a severe outbreak of diphtheria, not only are the local papers flooded with speculations as to the scientific explanation of outbreaks of diphtheria, but some medical practitioners describe their treatment in detail. It may be well to discuss in the newspapers the sanitation of dairies and of cows, but the attempt to describe the niceties of medical treatment is to be deprecated.

THE DANGERS OF CHILD LIFE.

ON the 21st inst. Dr. Tatham, medical officer of health for the borough, delivered an address at Salford on this subject. Of all the children born in the neighbourhood, Dr. Tatham stated that one-fifth die before attaining the age of one year. The proportion of infant deaths per 1000 births for the whole of England and Wales is about 130; in the Greengate district of Salford it exceeds 200. In Salford alone 1200 children die annually from the following causes: measles, 30-40; whooping-cough, 50-70; diarrhœa, 100-200, or more; consumption, 180-200; premature birth, 80-120; convulsions 150-200, lung diseases 100-300; whilst about 100 are found dead in bed, suffocated or overlain. Such a state of things was unnatural, and he desired to secure the co-operation of his hearers in reducing this excessive mortality. Dr. Tatham then discussed the causes of some of the diseases which are particularly fatal to children, and remarked that human life is of more value than that of sheep or pigs, and legislators ought to recognise this, and to see that means are adopted for the protection of human life, not less stringent than those already in force for the protection of cattle.

THE USE OF TOWN REFUSE IN ROAD-MAKING.

A DECISION has been come to by the corporation of Cardiff which is of considerable importance. It relates to the employment of the town refuse in making roadways. It appears that two years ago similar refuse was used in the construction of newly formed roadways in a low-lying district, where it was necessary that the roads should be considerably raised, and, according to the information before us, this is stated to have received the assent of the medical officer of health, subject to the surface and the sides of the roadways being constructed of marine clay, an arrangement intended hermetically to seal in any possible harm that might arise. We have not the full reports to refer to, but, so far as we can judge, the intention to extend this practice was recently preceded by an inquiry by the borough analyst, who emphatically condemns it. He has found that the roads in question, when opened up for the purpose, were wet, full of bacilli, and likely to cause serious evils, and so far from emanations being prevented from passing to adjoining houses, it has to be remembered that the lateral clay band, which rises to the height of the pavements, has to be intersected along its course by drain and other pipes. In short, any such hermetically sealing as was intended is practically impossible. Notwithstanding this, and apparently with the concurrence of the borough surveyor, it is announced in the *South Wales Daily News* that the Council have voted in favour of continuing a similar practice. On the subject generally, we may call to mind the report which was prepared for the borough of Liverpool in 1871 by Dr. Burdon Sanderson and the late Dr. Parkes. They sought to ascertain what was the effect of time on the animal and vegetable matters which in such a town necessarily becomes mingled with so-called dry house refuse, and their object was to advise the corporation how far such refuse might without risk be utilised for the purpose of filling up inequalities in the ground. The results of that inquiry are set forth in a detailed report; but for our present purposes it will suffice to point out that it was ascertained that "the process of decay for all the most easily destructible matters," including vegetable refuse, "is completed in three years," and the conclusion is drawn that "the vegetable and animal matter contained in the cinder refuse decays and disappears in about three years, and is virtually innocuous before that time." Faecal matter is not referred to in this connexion, and there was, of course, no attempt to hinder the process of decomposition by any clay seal, hermetical or otherwise. Possibly, this conclusion may aid the Cardiff corporation in arriving at a decision which will still enable them to utilise the materials referred to, and yet to do so without risk of causing injury to health. If such refuse could be properly stored at some depôt for a period bordering on three years, it is probable that at the end of that time the borough analyst would no longer object to its being used for the purposes indicated.

CHOLERA IN AUSTRIA-HUNGARY.

So far, there is no further report on the recent recurrence of cholera in Austria-Hungary. On Feb. 26th as many as twenty-five cases were stated to have occurred at Essegg, in Slavonia, seven of the attacks terminating fatally. This news was confirmed by further information on the 11th, to the effect that eleven out of eighteen patients had died there on the 10th. Essegg lies on the southern bank of the river Drau, just to the west of its junction with the Danube, and at a point where the river forms the boundary between Hungary and Slavonia. A large number of villages in Hungary were the seat of cholera in 1886, and it has all along been feared that, if any recurrence of the disease were to take place this year, its first appearance would be in this direction.

THE CUSTODY OF PERSONS ALLEGED TO BE LUNATICS.

THE law ought to define the conditions under which a person alleged to be a lunatic and giving trouble to those around, and say *where*, and *how*, he is to be protected during the delay so unwisely necessitated by legal enactment before such a person can be placed in an asylum. Meanwhile, we are not disposed to urge medical practitioners to go out of their way to help magistrates out of their difficulty in dealing with such cases. It would be far better policy, and conduce to the best interests of both the sane and insane, if matters were left to take their course, so that the defects of the law as it stands might, just now, be seen in their true aspect.

EXPERIMENTAL ALBUMINURIA.

SCHREIBER finds (*Arch. f. Exp. Path. u. Pharm.*, 1885-6; abstr. by Sabli in *Fortschritte der Medicin*, 1887, No. 2) that albuminuria may be artificially induced by compression of the thorax, the duration of the compression in young subjects needing to be only one minute and a half to produce the effect. The quantity of albumen is variable, but the time during which the albuminuria lasts varies directly with the duration of the compression. In one case hyaline casts, and in another blood-corpuscles were found in the urine. Schreiber refers the albuminuria under such conditions to stasis of the pulmonary circulation from diminution of the negative thoracic pressure, diminution of the normal difference in pressure between the pulmonary capillaries and left auricle, diminution of the vascular area in the lungs, and corresponding diminution of respiratory changes. In a second paper Schreiber describes the chemical characters of the albumen excreted in these cases, and gives cardiographic and sphygmographic tracings taken before and during the compression of the chest, which show a slight diminution in the fulness

Digitized by Google

of the peripheral arteries during the practice. Ophthalmoscopical examination did not show any variation in the size of the retinal vessels. These facts rather tend to throw doubt on the explanation of the albuminuria first offered, especially as no dyspnœa, such as would be expected from pulmonary stasis, is produced by the degree of compression sufficient to induce albuminuria.

FRENCH SURGICAL CONGRESS.

THE third meeting of the French Surgical Congress will be held in Paris in April of next year, the precise date of which has not been fixed, under the presidency of Professor Verneuil. The following questions, amongst others, are set down for discussion:—The treatment of gunshot wounds of the viscera; the value of the radical cure of hernia; and chronic suppuration of the pleura, and its treatment.

COLD AND THE TYPHOID BACILLUS.

DR. JOHN S. BILLINGS sends a note to the *Sanitary Engineer* of Jan. 29th (New York) respecting the influence of cold upon the typhoid bacillus. He found that cultures could be obtained from water which, after inoculation with the bacillus, had been frozen for some hours. Evidently, Dr. Billings adds, the vitality of the typhoid bacillus is not destroyed by freezing.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE following deaths are announced:—Dr. Alois Geigel, Professor of Hygiene in the University of Würzburg, at the age of forty-five. Dr. Richarz, founder of the Bonn Lunatic Asylum, one of the most famous alienists in Germany, at the age of seventy-five.

PORTUGUESE WORK ON RABIES.

DR. EDUARDO ABREU, of the Royal Academy of Sciences of Lisbon, who was appointed by the Portuguese Government to examine into M. Pasteur's treatment of hydrophobia has published a work upon rabies (*a Raiva*), in which, after describing the disease and referring copiously to the writings of observers in different countries, he gives the notes of the cases of Portuguese subjects who were sent to Paris, and also an account of some experiments made on rabbits (obtained from M. Pasteur) by himself. The work is, however, a relation of facts, rather than a critique upon them.

"ERYTHROMELALGY."

THE possibility of what has been spoken of as erythromelalgy being related in some way to a local asphxyia is certainly deserving of consideration. A case of the kind is recorded in *La France Médicale*, No. 14. It is that of a female aged twenty-six, a patient in the Salpêtrière. For eight years she had been subject to hysterical attacks of a classical description. The attacks had diminished in frequency the last two or three years. She had not suffered from an attack for more than three months, when she fatigued herself for several days in succession, after which she commenced to suffer with headache and hyperæsthesia of the skin, and went to bed in an agitated state. The next day her face was of scarlet hue, her eyes were injected, and she had beatings in the temples and violent palpitations, with severe occipital headache. At the same time she experienced smarting sensations on the back of the hands, and on the inner aspect of the thighs and arms. In a few moments there appeared red patches in the before-mentioned parts of the skin; they were discrete, and looked like erysipelas or scarlatina. The patches were irregular, and not raised at the edges. The red skin was dry, and hotter by 1° C. than the unaffected areas. The erythematous areas were not painful, but were the seats of an insupportable smarting. Their duration was about two hours. Their disappearance was followed by sweating and the passage of a large quantity of urine.

RECTAL GASEOUS MEDICATION FOR EMPHYSEMA.

PURSUING the plan of M. Bergeon, MM. Renault and Thierry have employed lavements of carbonic acid gas in the treatment of emphysema complicated with catarrh. The number of observations has been but small. The general method of treatment was the same as that employed for the treatment of phthisis, but the sulphurous water was omitted. The results were remarkably satisfactory, especially as regards the relief of cough and shortness of breath, a daily lavement for a week or a fortnight being the usual course.

FOREIGN UNIVERSITY INTELLIGENCE.

Bordeaux.—The chair of Chemistry is advertised as open to competition.

Berlin.—The temporary charge of the University Clinic for Women in Artillerie-strasse, vacant by Professor Schroeder's death, has been given to Dr. Hofmeier, the chief assistant physician.

Leipsic.—After having met with two refusals, the invitation of the University to fill the chair of Midwifery has been accepted by Professor Zweifel of Erlangen.

Moscow.—The new Clinic for Mental Diseases founded by Mdme. Morosoff has been formally opened.

Zurich.—The number of medical students here is larger than at any other Swiss University, being 241. Berne has, however, the largest number of female students—viz., 42.

THE following are the names of the gentlemen who form the medical staff of the London Throat Hospital recently founded in Great Portland-street, W.:—W. McNeil Whistler, M.D., M.R.C.P.; Edward Woakes, M.D. Lond.; George Stoker, M.R.Q.C.P.I.; W. H. Fenton-Jones, M.D., M.A. Oxon.; W. R. H. Stewart, F.R.C.S.; C. Coleman Jewell, M.B. Lond.; Edward Law, M.D. Aural Surgeon, Dr. Woakes; Pathologist, Dr. Jewell.

WE have been requested to call attention to the fact that the meeting of the Pathological Society next week will be held on Thursday, March 3rd, instead of Tuesday, when the annual meeting of the Royal Medical and Chirurgical Society takes place.

A VOLUME of papers by the late Dr. Moxon, bearing the title of "Pilocereus Senilis," is announced as ready for publication by Messrs. Sampson Low and Co.

DR. E. DRUMMOND of Rome will, we understand, contribute to an early number of the *Fortnightly Review* a paper on the health of that city.

METROPOLITAN HOSPITAL SATURDAY FUND.—The first meeting for the present year of the delegates of this fund was held on the 19th inst., when the certificates of 126 delegates were verified. It was resolved that the ladies' collection should take place on June 25th, and that a series of meetings be organised with a view to securing for the Jubilee year such an amount as shall be worthy of the working classes of London, and testify to their appreciation of the hospitals and dispensaries of the metropolis. Invitations have been issued to the officers of the Hospital Saturday movement in the provinces to attend a conference, to be held either in London or Birmingham during the ensuing summer.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5772 births and 3736 deaths were registered during the week ending Feb. 19th. The annual death-rate in these towns, which had steadily declined in the preceding six weeks from 26·5 to 19·5 per 1000, rose again last week to 21·1. During the first seven weeks of the current quarter the death-rate in these towns averaged 22·1 per 1000, and was 2·3 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 17·2 in Derby, 17·9 in Salford, 17·9 in Leicester, and 18·1 in Brighton. The rates in the other towns ranged upwards to 25·7 in Plymouth, 25·8 in Liverpool, 28·6 in Manchester, and 29·6 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding five weeks from 485 to 340, rose again last week to 371; they included 125 from whooping-cough, 107 from measles, 47 from scarlet fever, 36 from diarrhœa, 32 from diphtheria, 23 from "fever" (principally enteric), and only 1 from small-pox. The lowest death-rates from these principal zymotic diseases were recorded last week in Brighton, Derby and Leicester; and the highest rates in Bristol, Huddersfield, and Liverpool. The greatest mortality from whooping-cough occurred in Sunderland, Huddersfield, and Plymouth; from measles in Hull, Huddersfield, and Liverpool; from scarlet fever in Salford, Blackburn, and Bristol; and from "fever" in Preston. The 32 deaths from diphtheria in the twenty-eight towns included 15 in London, 3 in Portsmouth, 2 in Birkenhead, 2 in Liverpool, and 2 in Preston. Small-pox caused 1 death in Newcastle-upon-Tyne, but not one in London and its outer ring, or in any of the twenty-six other large provincial towns. Only 4 small-pox patients were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 364 and 373 in the preceding two weeks, further rose last week to 392, but were 149 below the corrected average. The causes of 95, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Blackburn, Norwich, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Brighton, Leicester, Salford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·8 and 22·0 per 1000 in the preceding two weeks, further rose in the week ending Feb. 19th to 24·3; this rate exceeded by 3·2 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·7 in Greenock and 14·6 in Perth, to 26·6 in Aberdeen, 27·0 in Glasgow, and 28·2 in Paisley. The 607 deaths in the eight towns last week showed a further increase of 57 upon the numbers returned in the preceding two weeks, and included 32 which were referred to whooping-cough, 25 to scarlet fever, 23 to measles, 14 to diarrhœa, 5 to diphtheria, 4 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all 103 deaths resulted from these principal zymotic diseases, showing a further increase upon the 66 and 76 returned in the previous two weeks. These 103 deaths were equal to an annual rate of 4·1 per 1000, which exceeded by 2·0 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 19, 23, and 28 in the preceding three weeks, further rose last week to 32, of which 22 occurred in Glasgow, 4 in Aberdeen, and 3 in Edinburgh. The deaths from scarlet fever and from measles also showed a considerable further increase upon recent weekly numbers; the 25 fatal cases of scarlet fever included 16 in Edinburgh, 5 in Glasgow, and 3 in Dundee; of the 23 deaths from measles, 12 occurred in Glasgow and 9 in Aberdeen. The 14 deaths attributed to diarrhœa included 7 in Glasgow, 3 in Dundee, and 3 in Aberdeen. Three of the 5 fatal cases of diphtheria and 2 of the 4 deaths from "fever," were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 126 and 133 in the preceding two weeks, further rose last week to 146, but were 7 below the number returned in the corresponding week of last year. The causes of 69, or more than 11 per cent., of the deaths registered during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 29·7 and 27·3 per 1000 in the preceding two weeks, rose to 35·3 in the week ending Feb. 19th. During the first seven weeks of the current quarter the death-rate in the city averaged 31·5, the mean rate during the same period being but 20·9 in London and 21·8 in Edinburgh. The 239 deaths in Dublin last week showed an increase of 54 upon the number in the previous week, and included 4 which were referred to "fever" (typhus, enteric, or simple), 3 to scarlet fever, 3 to diarrhœa, 2 to whooping-cough, 1 to measles, 1 to diphtheria, and not one to small-pox. Thus the deaths from these principal zymotic diseases, which had been 13 and 17 in the preceding two weeks, declined again last week to 14; they were equal to an annual rate of 2·1 per 1000, the rates from the same diseases being 1·5 in London and 4·0 in Edinburgh. The deaths referred to "fever," corresponded with the number in the previous week, while the fatal cases of scarlet fever, diarrhœa, and whooping-cough each showed a decline. The deaths of infants exceeded the number returned in any previous week of this year, and those of elderly persons also showed an increase upon recent weekly numbers. Five inquest cases and 2 deaths from violence were registered; and 81, or more than a third, of the deaths occurred in public institutions. The causes of 33, or nearly 14 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

THE following is added after paragraph 1244 of the Regulations for the Army Medical Department, 1885:—Whenever a medical officer is required to report, in the case of individuals injured in the Service, upon their capability, or otherwise, to contribute to their own support, the greatest care will be observed by him in forming and recording an opinion, as it is mainly upon such opinion that the important question of granting compassionate allowances or gratuities has to be considered.

Deputy Surgeon-General J. B. C. Reade, C.B., has handed over his charge at Umballa and proceeded on leave of absence, and has been replaced at Umballa by Deputy Surgeon-General J. Landale, M.D.

Surgeon-Major F. A. Turton has been brought in from the temporary half-pay list, and has joined the Northern District for duty at Birmingham in charge of the detachment there stationed.

WAR OFFICE.—Army Medical Staff: The undermentioned Surgeons have been seconded for service with the Egyptian Army: William Henry Phillips Lewis, Aylmer Ellis Hayes, Arthur Maher Kavanagh, and Richard Edward Ricketts Morse.

INDIA OFFICE.—The Queen has approved of the retirement from the Service of the undermentioned officer of the Indian Military Forces: Surgeon-Major John Proudfoot Stratton, M.D., of the Bombay Medical Establishment. The Queen has also approved of the undermentioned officers being granted a step of honorary rank on retirement: Deputy Surgeon-General Charles Planck, Deputy Surgeon-General Alfred James Dale, and Deputy Surgeon-General John Brake, all of the Bengal Medical Establishment, and Deputy Surgeon-General Henry Cook, M.D., of the Bombay Medical Establishment, to be Surgeons-General; Brigade Surgeon James Fairweather, M.D., Brigade Surgeon James Browne, M.D., and Brigade Surgeon Robert Sander Bateson, all of the Bengal Medical Establishment, to be Deputy Surgeons-General; and Surgeon-Major John Proudfoot Stratton, M.D., of the Bombay Medical Establishment, to be Brigade Surgeon.

ADMIRALTY.—The following appointments have been made:—Surgeon John N. Corbett, to the *Orwell*; Mr. Patrick J. Sheridan to be Surgeon and Agent at Kilmore; and Mr. George C. Dickson to be Surgeon and Agent at Whitehaven.

ARTILLERY VOLUNTEERS.—1st Banff: Acting Surgeon James Hitchcock, M.B., resigns his appointment.—1st Volunteer (Hampshire) Brigade, Southern Division, Royal

Digitized by Google

Artillery: Surgeon Burford Norman is granted the honorary rank of Surgeon-Major.—1st North Riding of Yorkshire: Friend Edward Streeten, Gent., to be Acting Surgeon.

ENGINEER VOLUNTEERS. — The Volunteer Submarine Miners (the Humber Division): Edward Furniss Potter, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Volunteer Battalion, Princess Charlotte of Wales's (Royal Berkshire Regiment): James Hopkins Walters, Gent., to be Acting Surgeon; Frederick William Dyce Fraser, M.D., to be Acting Surgeon.—2nd Cambridgeshire (Cambridge University): James Hayward Hough, Gent., to be Acting Surgeon.—4th Cheshire: Kenneth Maclean, Robert Alexander Murray, M.B., and John Keay, to be Acting Surgeons.—1st Midlothian (Leith): James Mill, M.B., to be Acting Surgeon.—2nd Shropshire: Surgeon and Honorary Surgeon-Major F. J. Sandford, M.D., resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement.

Correspondence.

"Audi alteram partem."

ASPIRATION OF THE URINARY BLADDER.

To the Editors of THE LANCET.

SIRS,—At the meeting of the Medico-Chirurgical Society last Tuesday, Mr. William H. Bennett read a paper on a case of aspiration of the bladder which ended fatally, and in the course of his remarks said that the text-books taught that aspiration of the bladder was a harmless operation. Owing to the discussion on Mr. Morris's important paper, there was no opportunity of replying to Mr. Bennett, and I therefore, with your permission, beg leave to state that in my article on Retention of Urine, in Mr. Christopher Heath's "Dictionary of Practical Surgery" (vol. ii., p. 335), I am careful to say that "fatal extravasation and abscess have been known to follow a second aspiration," and I based this remark upon a case published some years ago by Dr. Macfie Campbell of Liverpool. Other fatal cases of aspiration have been published (e.g., by Mr. Treves, THE LANCET, August, 1880), in all of which I find that over-distension of the bladder was allowed to recur after the relief obtained by aspiration. If, after aspiration, the bladder is kept free from over-distension by the introduction of a catheter—often easy enough when the urgent symptoms have been relieved—or by a second or a third aspiration, the operation is a safe one. I am well aware that a bladder has been aspirated twenty times in immediate succession safely; still, I do not consider such a proceeding good practice, and, in the article above referred to, I advise that in the event of more than two or three aspirations being required, supra-pubic puncture with trocar and cannula should be performed. Mr. Bennett's case furnishes valuable additional evidence that aspiration must not be inconsiderately resorted to, but the operation is such a safe and useful one in certain rare cases of retention where an instrument cannot at the moment be introduced by the urethra, that it is a pity it should in any way be discredited. I make no reference to the treatment of a rotten bladder (the expression used by Mr. Bennett), because I am not aware of the existence of such a condition in acute retention of urine. By the time a bladder deserves to be called rotten Nature has anticipated the surgeon and has relieved herself by rupture, requiring appropriate treatment, which is certainly not aspiration. I am, Sirs, yours truly,

Wimpole-street, W., Feb. 23rd, 1887. G. BUCKSTON BROWNE.

THE MEMBERS OF THE COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—We trust that you will forgive us for offering a few further details as to the signatures (now over 4600) received to the petition of the Members of the College of Surgeons to the Privy Council. By the end of last year the number was 1430, chiefly obtained by personal solicitation; but we felt then that we might expect a very much larger total than this, and consequently issued about 9000 forms of the petition to Members of the Royal College of Surgeons in the United Kingdom who had not already signed, this number covering all those whose addresses appear in the Medical Directory. It has been most satisfactory, seeing the usual fate of a circular, that over one-third of this number have been returned to us, and that we have what may fairly be called almost half of the Members resident in the United Kingdom, whose present addresses are *discoverable*, as signatories to the petition. We make no manner of doubt that by a "house-to-house visitation," as you suggested a few weeks ago, the overwhelming majority would be in our favour. But we do not think the expenditure of energy and money at all necessary, the more especially as the probable result of such a measure is clearly shown by the following statistics:—Out of 503 Members of the Royal College of Surgeons placed on the local list of the Medical Directory for 1887 as resident in the following eighteen provincial towns—viz., Bath, Bolton, Bradford, Bristol (and Clifton), Cardiff, Chichester, Great Malvern, Middlesborough, Ramsgate, Scarborough, Shrewsbury, Southampton, Swansea, Wigan, Windsor, Worthing, Yarmouth, and York—359 have signed, which, allowing for about 23 of the 503 being either marked as "retired," or with an asterisk, as of *uncertain* address, gives a proportion of three-fourths who have signed—75 per cent. We instance these places, as in them our local hon. secretaries have been very active in getting the question ventilated; and it is far more just to argue from such localities than from very large, unwieldy cities or country districts, where our circular is the only intimation Members have had that such a movement was on foot, and where, consequently, their interest has not yet been aroused in it. Of the towns mentioned above, we would especially lay stress on Bristol, from which and from Clifton our local hon. secretary, Mr. Samuel Smith, sent us the petition, signed by sixty Members—i.e., by *half* of the Members residing there,—twenty-four of the remaining half sending their signatures later on our circular forms. The Council of the College are really responsible for this widespread expression of opinion; for, had they moved forward more quickly with their application for a new Charter, we should not have had the time to get our aims so widely known. Shall we call this generosity on their part? As to any feeling contrary to our proposals existing among the Members, we may inform you that we have had only fourteen expressions of objection to the memorial—fourteen against 4600.—We are, Sirs, your obedient servants,

WARWICK C. STEELE, } Hon. Secs., Assoc.
WM. ASHTON ELLIS, } of M.H.C.S.

Western Dispensary, Westminster, S.W., Feb. 16th, 1887.

LUNACY ACTS AMENDMENT BILL, 1887.

To the Editors of THE LANCET.

SIRS,—Permit me to draw the attention of workhouse medical officers to the injustice which it is proposed in the Lord Chancellor's Lunacy Act Amendment Bill to perpetrate on them by the provisions contained in Clause 14, Sections 5, 6, 7, 8, page 13, whereby it is arranged that they shall be debarred by statute from receiving any remuneration whatever for the examination and certification of a lunatic received into the workhouse of which they are the medical officers, and that they shall be subjected to a fine of £10 for any day or part of a day they neglect to supply a certificate for nothing. Some forty-five to fifty years ago a similar proviso was made, but, the great injustice implied therein having been made manifest, the restriction was removed, and guardians were permitted—nay, encouraged—by the Commissioners in Lunacy to allow the workhouse medical officer to perform this duty and to pay him a fee varying from 10*s.* 6*d.* to 21*s.* The reason given for the prohibition in the first instance and for its repetition now is the feeling entertained by certain persons in the medical and legal professions that the workhouse medical officer would abuse his position for the sake of the fees above named in certifying that all and sundry of the inmates of the house were of unsound mind, wholly oblivious of the fact that when certified to they at once pass under the skilled superintendence of the principal medical officer of the asylum to which they may be sent, who would speedily report upon any abuse of authority by the workhouse medical officer or by his substitute. Before concluding, I should like your readers to understand that, with the rare exception where an inmate becomes insane, all persons admitted to a workhouse alleged to be of unsound mind go there with a certificate from the district medical officer, the divisional surgeon of police, or by the order of a

Digitized by Google

police magistrate or justice of the peace. It should be remembered that it not unfrequently happens that the workhouse medical officer is specially sent for on the admission of a lunatic, and perhaps may have to travel four or five miles, and that he is liable to be assaulted, as I have been in years gone by, by an excited lunatic. Yet all this is to count as part of his duty, for which he is to receive no consideration of any kind—nay, many workhouse medical officers will lose much of their emoluments when the Bill becomes law. It is probably hopeless to expect that the law lords will modify these sections, but it is to be hoped that some medical members of the Lower House will enter an opposition to them; at any rate, I feel that I am only doing my duty to my former colleagues in raising this objection.—I am, Sirs, yours obediently,

JOSEPH ROGERS,
Chairman of the Poor-law Medical Officers' Association.
Montague-place, W.C., Feb. 21st, 1887.

"INFANT MORTALITY AT WORKINGTON."

To the Editors of THE LANCET.

SIRS,—Kindly allow me to state that the annotation headed "Infant Mortality at Workington," in the last issue of THE LANCET, was written without adequate knowledge. I am not responsible for the comments of *The Times*, and the report in that journal was not accurate.

As to my remarks on scarlet fever, I was alluding to a few cases in the district during the latter half of the year, and I wrote: "Should the disease appear to spread to a dangerous extent, I shall advise you to have the schools closed." I presume that you will agree with this. During 1885 a malignant form of measles broke out here. I argued the question of school-closing first with the Local Board, and then with the School Board. Time and lives were lost in consequence. Indeed, from Oct. 4th, 1885, to the end of March, 1886, there were sixty-three deaths from measles. I did not wish for this delay over a probable scarlet fever epidemic, as to be forewarned is to be forearmed; hence my remarks. You mention "fatality amongst children at the school age, and not among young infants." My opinion is, that so long as there is scarlet fever in a house all the children in such house should remain away from school. I have not stated that 136 per 1000 is a high infantile death-rate, and, moreover, I turned my attention to the Registrar-General's reports. I stated that the infantile mortality in Workington might be less, and gave reasons which are defensible. You would appear to argue that because infantile mortality is low in Workington, when compared with the same mortality in all England and Wales, I should be silent on the subject. But if I know from personal observation that the infantile mortality in Workington can be reduced, surely you will agree that it is my duty to show how this may be effected.

I submit, therefore, that my "scathing condemnation" was not based on "insufficient data." My report is being printed, and you shall have a copy of it at an early date. In the meantime, I am convinced that a report should be couched in the terms best suited to the people for whom it is written. I might show this from the improvements effected in Workington during my term of office, but I avoid egotism. My object is not to write useless disquisitions on vital statistics, but to point the way to sanitary reform and thereby ameliorate the conditions of the public health.

I am, Sirs, your obedient servant,

JOHN LOWE,
Workington, Feb. 21st, 1887. Medical Officer of Health.

DOES LACERATION OF THE CERVIX UTERI MORE COMMONLY OCCUR IN FIRST LABOURS OR IN SUBSEQUENT ONES?

To the Editors of THE LANCET.

SIRS,—In Dr. John Williams' third Lecture on Cancer of the Uterus, published in your issue of February 12th, at page 301, the following sentence occurs: "Indeed, it may fairly be said that when laceration is present the time when it was produced was during the first labour." I have seen a large number of cases of laceration of the cervix, and have good notes of sixteen cases, in thirteen of which I have done Emmet's operation. In eleven of these cases it was possible to tell with tolerable certainty during which confinement the accident had occurred, and in one only had it taken place during the first, and this patient has not subsequently borne children. The labour at which the laceration had probably occurred was usually the last, or the last but one or two, the average being 5·24, the total average of confinements of these eleven being 5·63 for each patient. Of course these numbers are small, and my conclusion or inference that the laceration occurred at a certain labour, and not at a preceding or subsequent one, may not have been invariably correct, but there was usually very good ground for the conclusion. So far as they go, however, these cases show that laceration is uncommon at the first labour. The explanation probably is that although at the first confinement the os dilates more slowly, it is in a healthy condition, and it is not so likely to tear as after the parts have lost to some extent their power of resistance from inflammatory action, the result of previous hard labours.

I am, Sirs, your obedient servant,

JAMES BRAITHWAITE, M.D.,
Feb. 22nd, 1887. Obstetric Physician to the Leeds General Infirmary.

THE PREVENTIVE TREATMENT OF SYPHILIS AND OF HYDROPHOBIA.

To the Editors of THE LANCET.

SIRS,—Referring to the annotation in your issue of the 19th inst., which states that Dr. Andronico claims to have eradicated the syphilitic virus in four cases by excising the primary growths, permit me to point out the superiority of destroying chancres by means of the thermo-cautery as obviating the risk of reinfection of the system during the actual performance of the operation. I can now inform your readers with regard to the case of Mr. A. B. C. (published in THE LANCET, July 17th, 1886), in which I destroyed a Hunterian chancre on Nov. 11th, 1885, with Pacquelin's cautery, and upon the suggestion of Sir William Jenner, carried out a course of mercurial treatment, that when I last saw the patient in September, 1886, there had up till that date been no secondary manifestations of syphilis.

On Oct. 18th, 1886, I saw a patient in consultation with Mr. Abbott of Braintree. A typical hard chancre existed on the left side of the corona penis, and its development had been noticed to have commenced since Oct. 13th. This was destroyed with Pacquelin's cautery, the part having been previously painted with a solution of cocaine to mitigate the pain, as in the case of Mr. A. B. C. A mercurial course was also suggested, and I have no doubt Mr. Abbott will be happy to report in due time the effect of the treatment. Here five days had elapsed since the first suspicion of infection before the destruction of the chancre, and such a delay is no bar to attempting the eradication of the virus—not even if the nearest lymphatic glands be enlarged, since this enlargement is probably at first of a simple and only later of a specific character. Owing to the very strong analogy which exists between the natural histories of syphilis and hydrophobia, *a fortiori* to the longer period of latency of the latter disease, there is ground for recommending that in all suspected cases of hydrophobia the earliest attempt to destroy the virus at the seat of inoculation should never be omitted. Add to these considerations the fact that only from 5 to 50 per cent. of those bitten by dogs and other animals, rabid or otherwise, really receive the virus of hydrophobia, and the argument in favour of treating these patients in the first instance by applying the thermo-cautery thoroughly to the cocainised part becomes insuperable. The method is simple, and any practitioner in England can carry it out readily.

I am, Sirs, your faithful servant,

CHAS. E. JENNINGS, F.R.C.S. Eng.
Upper Brook-street, Grosvenor-square, W., Feb. 19th, 1887.

THE JUBILEE.—The committee of the proposed Victoria Hospital at Bournemouth have received promises of subscriptions amounting to £2800 towards the hospital which is to be erected in commemoration of the Queen's Jubilee. The committee of the existing Cottage Hospital and Dispensary have £2000 in hand towards the erection of a building (which has been contemplated for several years past), and they have agreed to hand over this sum, together with their interest in the present building &c., to the public committee, in order that there shall be one large and central institution.—At a meeting of working men, at Mansfield, on the 16th inst., resolutions in favour of the proposed establishment of a hospital to celebrate the Jubilee were adopted.

MANCHESTER.

(From our own Correspondent.)

HOSPITAL SUNDAY.

ON Sunday, the 13th, the annual collections were made on behalf of the hospital funds. A special appeal had been issued by the hon. sec. (the Rev. J. Henn), who, through the medium of the press, gave a brief account of the work carried on by our various medical charities. He gives some interesting figures respecting the consumption of alcohol at the Royal Infirmary, which showed that whilst in 1876 the cost per patient for alcoholic stimulants averaged 5*s.* 0½*d.* per head, it had steadily diminished to only 1*s.* 2¼*d.* per head in 1886. It is too soon to say with certainty what the amount of the collections will probably be, but the returns, so far, do not show much increase upon last year, notwithstanding that the weather on Sunday was favourable.

CHILDREN'S HOSPITALS.

Amongst the many projects put forward here in the name of the "Jubilee Year," one of the most deserving is perhaps the suggestion to build a children's ward to the Ardwick and Ancoats Hospital. Situate as this is in the midst of a densely populated district, its usefulness cannot be gainsaid, for, notwithstanding the work being done on the opposite side of the city by the Pendlebury Children's Hospital, there is more than sufficient sickness and accident to keep a children's ward here always full. Some attention is at present being directed to the fact that at the Children's Hospital, Pendlebury, cases of infectious disease are received, and it is alleged that it is by no means an unknown thing for children who have been under treatment in the general wards to have to be transferred to the "fever" ward, and it is insinuated that children admitted for one disease have contracted another after admission. If this be so, and it has not been denied, the serious attention of the management should be directed thereto, for nothing can be more damaging to the reputation of a hospital than that the idea of the possibility of such a thing happening should get abroad in the public mind. It is true that the "fever ward" is isolated so far as a ward can be isolated that opens out of the main corridor, and it is known that the late Dr. Borchardt (to whom the hospital owed very much) had very strong opinions that with due precaution no harm was to be feared. It is for the authorities to show from past experience that there is no ground for alarm, for if otherwise, seeing that we are well provided with hospital accommodation for infectious diseases elsewhere, the practice of treating fever patients at a general hospital ought not to be followed.

LIMITATION OF INFECTION.

The Manchester guardians have lately been again urged by the Government inspector to provide some means of isolation for doubtful and infectious cases of disease occurring among the children at their schools at Swinton, but they appear to be loth to comply with the recommendation. The ophthalmia which for a long time was so prevalent there is now very much diminished. It is satisfactory to note the co-operation of the Poor-law authorities with the health authority in endeavouring to cope with the spread of infection in large communities like this. The medical officer of health of Salford met the guardians last week, recommending certain precautions in dealing with tramps, &c., with a view to arresting the threatened spread of small-pox in their district. His suggestions were received with favour by them. The infant mortality in Salford still continues alarmingly high from suffocation, the Salford coroner recently stated that within two months he had held inquests on the bodies of thirty infants, in all of which the verdict had been "accidental suffocation." Probably a few committals on a charge of manslaughter would tend to diminish these "accidents."

SANITATION.

At the annual meeting of the Sanitary Association a good report was given of the year's work in endeavouring to remedy sanitary shortcomings and promoting a spread of sanitary knowledge among the people. The balance-sheet showed an adverse balance of £36, and an appeal is made to the public for a little more support in aid of the voluntary work undertaken by the Society. Considering the smallness of the sum annually at their disposal, much credit is due to the committee for the results obtained. Amongst one of the latest matters to which they have directed attention is a memorial to the corporation urging the desirability of publishing their health report annually as in other towns, instead of biennially, as is now the case, and suggesting that it should contain some more detailed statement of the work and operations of the Health Committee, which hitherto the reports have not contained. Seeing that at the present time this department of the corporation is about to undergo a strict inquiry into all its operations and various works, the suggestion is a timely one.

The election of Dr. Morgan, Professor of Medicine at Owens College, as a member of the Council of the London College of Physicians, has given much satisfaction here, it being some time since Manchester was represented upon that august body.

Feb. 15th, 1887.

EDINBURGH.

(From our own Correspondent.)

ROYAL SOCIETY OF EDINBURGH.

AMONGST the papers read at the last meeting of this Society was one by Professor Tait upon the effects of dynamite explosions. In a recent explosion of dynamite on the London Underground Railway it was noticed that many of those injured suffered from rupture of one membrana tympani, the other being unaffected. Professor Tait explains this by a reference to the physical nature of a dynamite explosion. At the centre of explosive violence a state of physical conditions is present different entirely from that which obtains at a very slight distance from the centre. The explosion is so instantaneous throughout the whole of the explosive material, that the projected gases travel from the centre of explosion at first more rapidly than the rate of transmission of sound. Light is produced at the immediate seat of explosion, from the compression of atmospheric air by the liberated gases, the air becoming self-luminous by the instantaneous compression. It is only at an appreciable distance from the centre of explosion that the velocity is reduced to that of sound transmission; up to that point there would be an excessively intense impulsive pressure, which would be likely to produce very considerable damage. In this respect dynamite differs totally from gunpowder, in which a much slower combustion takes place, so that the effects of increased pressure with graduated speed are produced; whereas in dynamite the maximum impulse is of instantaneous production.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

The last two sessions have witnessed a considerable increase of activity in the work of this Society. Under the able presidency of Professor Grainger Stewart the number of meetings held and the amount of work produced at them have been largely augmented, and a number of special interim meetings have been held for the discussion of special topics. Last week the Society met at the College of Physicians, when the subject of Empyema was fully discussed in all its aspects. The discussion was opened by Dr. William Russell, who read a paper detailing his own experience in the matter. He advocated early and complete drainage, with strict antiseptic precautions, citing a successful case of his own in a child of six weeks old, and exhibiting patients to illustrate his results in other cases. Dr. Caverhill expressed himself in favour of a system of expanding the lung by pneumatic exhaustion. Mr. Duncan referred at length to aspiration, drainage, and removal of a segment of the chest wall as the three types of surgical interference, each of which had its appropriate uses, the first and the last in relatively few cases, free drainage, with the removal of a piece of a single rib, being the treatment usually most satisfactory. In this operation he dispenses with the carbolic spray. Dr. Affleck referred to the value of the hypodermic needle as a diagnostic agent. He also gave some interesting facts in regard to the treatment of empyema carried on by Hippocrates and his disciples, showing on how philosophic a basis, and how near to modern practice, was the procedure of the Father of Medicine. Dr. James illustrated the action of the pleura in respiration, showing how morbid processes spread from part to part of the membrane;

Digitized by Google

Dr. Byrom Bramwell deprecated active exhaustion of the pleural cavity, as liable to produce further complications by the bursting outwards of morbid accumulations near the surface of the lung. Dr. William Hunter spoke of absorption from serous membranes, showing that a partial removal of serous effusion is best calculated to result in the absorption of the remainder and a return to the normal condition. Dr. Brakenridge, Mr. A. G. Miller, Dr. John Thomson, Mr. Hare, and Dr. Leith Napier also took part in the discussion. It is probable that other similar discussions will be arranged for during the remainder of the session.

THE SCARLET FEVER EPIDEMIC.

The serious epidemic of scarlet fever that has prevailed in the west and north districts of the city for some days has apparently reached its apogee, and is beginning to wane. On Monday only fourteen fresh cases were intimated, a great diminution as compared with last week, when the number was between fifty and sixty daily. It is satisfactory also to learn that there is a corresponding diminution in the intensity of the disease in the cases now occurring. A great deal of public interest is evidenced in a discussion now carried on in the local papers as to the supposed connexion of the disease with a bovine disorder. It does not appear, however, that there is any proved connexion in this case between the epidemic and the milk-supply.

THE STUDENTS' UNION.

A site has now been purchased for the Union buildings, adjacent to the new medical buildings of the University, at a cost of £2000. The building is to be designed by Mr. Sydney Mitchell, architect, who has done much to beautify Edinburgh by buildings planned by him. It will cost £8000. That and the cost of the site take up £10,000 of the £13,500 in the hands of the acting committee. £1500 are still required to complete the £15,000 necessary to carry out the whole scheme. The building will contain a hall seating 500 persons, reading, writing, luncheon, and committee rooms, and a well-equipped gymnasium.

Edinburgh, Feb. 22nd.

DUBLIN.

(From our own Correspondent.)

THE CONJOINT SCHEME BETWEEN THE TWO COLLEGES.

As was generally expected, the proposed conjoint scheme between the Royal College of Surgeons and the College of Physicians has been referred back to those colleges for reconsideration by a large majority of the General Medical Council. The exclusion of the Apothecaries' Hall is mainly due to the Fellows of the College of Physicians, who appear to consider it derogatory to be associated with the Apothecaries' Hall in any conjoint scheme. To use an expressive word, the College of Physicians is an "uppish" corporation, and by 17 to 4 has recently declined to reopen the question of the constitution of the joint examining board. I recently alluded to the suggestion made by some of the Council of the Royal College of Surgeons that a dual combination might be formed between that institution and the College of Physicians on the one hand, and also with the Apothecaries' Hall and the College of Surgeons on the other. Should the College of Physicians refuse to admit the Apothecaries' Hall into the scheme, they will commit a fatal error by lowering the tone of medical education in this country. Besides this, sooner or later the Apothecaries' Hall will be joined in the scheme with the College of Surgeons, and, should the College of Physicians withdraw, the latter body will, in my opinion, not have a very long tenure of existence.

DUBLIN HOSPITAL SUNDAY FUND.

The thirteenth annual meeting of the supporters of this fund was held last week. The total amount of contributions for 1886 was £4158 0*s.* 3*d.*, being a decrease of £310 5*s.* 5*d.*, as compared with the previous year. Last year the Committee of Distribution were requested to form a committee to inquire into the dietaries of the participating hospitals, and report to the council. This committee now reported that considerable differences existed in quantity between some of the principal items of diet among some of the general hospitals. For example, in the Whitworth Hospital the daily allowance of bread amounts to 18 oz., and potatoes 20 oz., while at Sir Patrick Dun's the daily allowance to the patients is only 12 oz. and 4 oz. respectively, a discrepancy which appears inexplicable. As the committee remark, these returns point either to waste in the former or short allowance in the latter institution.

THE TOXICITY OF SILICON FLUORIDE.

Sir Charles Cameron has recently published some remarks on the toxicity of this gaseous substance, consequent on two fatal cases which occurred in Dublin. The manure factory where these deaths took place is for the manufacture of superphosphates, and the phosphatic material used contains an unusually large amount of fluoride of calcium. On treatment with acid, this would evolve very large quantities of carbon dioxide and fluorine compounds. The symptoms in the last case and the condition of the lungs and heart, as shown by a post-mortem examination, indicated death by asphyxia. An analysis of a portion of one of the lungs showed that the whole organ contained at least 0·75 gramme of silica (SiO_2). When silicon fluoride comes into contact with the moist surface of the respiratory passages, it deposits thereon gelatinous silica and fluosilicic acid. The silica being in the colloidal state opposes great resistance to the passage of gases, and it forms a glaze or varnish on the walls of the bronchi and their ramifications. As it is not absorbable into the circulation, it can only be got rid of by expectoration. Sir Charles Cameron is of opinion that it probably acts as an irritant to the nerves of the smaller bronchi, causing their muscles to contract spasmodically, thereby diminishing the area of the passages between the trachea and the air-vesicles. The fluosilicic acid, being readily soluble, passes into the circulation, and acts as a nerve poison. It may act directly upon the filaments of the pneumogastric nerve, and paralyse their action.

THE JACOB TESTIMONIAL.

Up to last Saturday the total promised or paid towards this testimonial amounted to £450, and as the subscription list will close in a few days it is absolutely necessary that those intending to subscribe should do so without delay. If the Poor-law medical officers of Ireland have any gratitude, they most certainly should contribute towards this testimonial to Dr. Jacob, who for so many years has befriended them in various ways. They may not be in a position to give large sums, but surely none would miss half a guinea, or even less, in showing their appreciation of his services.

ALLEGED ASSAULT ON A LUNATIC BY AN ATTENDANT.

Last week an attendant of the Limerick District Lunatic Asylum, named Fitzgerald, was prosecuted at the Petty Sessions for having violently assaulted an inmate named Cooney on the 27th ult. The latter gave his evidence in a very coherent manner, and stated that without any provocation whatever the prisoner had brutally assaulted him by kicking him in the abdomen. He reported the matter to the resident medical officer the following morning, and identified Fitzgerald from among several other attendants as his assailant. Dr. Gelston, the visiting physician, deposed to the injuries inflicted on the lunatic, and the case was returned for trial to the assizes, bail being accepted.

SINGULAR CASE OF SUICIDE.

A man named Martin Doyle, aged thirty-three, committed suicide last week in Dublin while apparently labouring under mental derangement. The deceased lived with his brother, and on the latter coming home after work he found Martin lying on his bed bleeding profusely from a number of self-inflicted wounds. He was removed to hospital, where he died two hours afterwards from hæmorrhage. The number of wounds on his body was very considerable, over twenty being on the head alone, while above the heart were two deep gashes, which penetrated to the lungs; the brachial artery also was cut across. The instruments of destruction which the unfortunate man used consisted of some common 2 in. nails and pieces of window-glass. Pins were also found sticking in various parts of the body of the deceased. The deceased was of a morose temperament, and, it is stated, about two years ago suffered from some head affection.

ZYMOTIC DISEASES IN DUBLIN DURING 1886.

The deaths from zymotic diseases numbered 1100, being 217 under the number for the preceding year, and 442 under the average for the ten years 1876-85. Measles only caused 9 deaths, against 296 in the previous year; scarlatina 191 deaths, showing a trifling increase; whooping-cough, 246, of

Digitized by Google

58 in excess. There were also 28 deaths from cerebro-spinal fever. The mortality from fever was much below the average, the deaths numbering 193, or 108 below the average for the past ten years. It is satisfactory to note that there has been a great decrease in the number of cases of typhus treated in the Dublin hospitals during the past few years; thus, in the year 1883 the cases admitted numbered 829; in 1884 the number was 469; in 1885 they fell to 247; and last year there was a further decline to 123.

Robert Browne, F.R.C.S.I., of Largo House, Rathmines, has been placed on the Commission of the Peace for co. Dublin.

Dr. Falkiner has been appointed Physician to the Whitworth Hospital. There is no salary attached to the post.

Dublin, Feb. 22nd.

BELFAST.

(From our own Correspondent.)

THE ULSTER HOSPITAL FOR WOMEN AND CHILDREN.

FROM the report read at the annual meeting of this charity, I learn that a large cheerful women's ward has been added to the hospital, and a new dispensary and waiting-room; and further, the whole house has been cleaned and painted. The number of students attending has been larger than in any former year. There have been some changes in the medical staff, owing to the death of Dr. Malcomson and the resignation of Dr. Poole, and Dr. Barron and Dr. Strafford Smith have been appointed in their place. The President of Queen's College, who was present at the meeting, referred in terms of the highest praise to the late Dr. Malcomson. He said that he was now greatly pleased to know that the hospital had as many beds as would satisfy even the exacting Senate of the Royal University. He regretted to have to make that statement concerning the Royal University, but one could never tell what changes might be effected in the demands of that university in the curriculum laid down for students. Financially the hospital is in a good condition, there being a balance in hand of over £44. Lady Johnston has given £250 in aid of the expenses incurred in the alterations in the hospital.

THE MEDICAL STUDENTS' ASSOCIATION.

A conversazione, under the patronage of the President and Professors of Queen's College and the medical staff, will be held in the Queen's College on Thursday, March 10th. The students and their friends are exerting all their efforts to make the entertainment a success. It will be held in the same rooms as those in which the brilliant conversazione took place at the meeting of the British Medical Association.

THE ULSTER MEDICAL SOCIETY.

The annual dinner of this Society was recently held in the Royal Avenue Hotel. The President (Dr. Whitla) occupied the chair. Upwards of forty members of the medical profession were present, and the evening was a decided success. The Society is in a very flourishing condition, and the plan adopted this year of taking up special subjects at the meetings has tended to increase the attendance and interest of the members. Already we have had a sanitary night, and at the last meeting the treatment of phthisis formed the subject. Very good papers were read by Dr. Cuming, Dr. Lindsay, and Dr. Sinclair, the discussion being adjourned until the next meeting.

Belfast, Feb. 15th.

MONTREAL.

(From a Correspondent.)

MATTERS medical remain very quiet in this part of the country. Before Christmas both medical schools—McGill and Bishop's—held their annual undergraduates' dinners, which were well attended by present students, with a fair proportion of graduates. These annual dinners, which were evolved from the old "footing dinner" some three or four years ago, may be taken as evidence of the change which has come over the medical student during the past decade. Whereas the "footing dinner" was simply nothing but drunken revelry, the present annual dinner is a gathering of gentlemen.

The Faculty of Arts students at McGill, who have long worn the gown in and about the College, have recently decided to wear the trencher also. The science students have likewise decided in favour of the trencher.

A very unusual case recently presented itself at the Montreal General Hospital—viz., a case of true scurvy in a farm labourer from the eastern townships. Although working on a farm, the man's diet for the past twelve months had consisted of bread-and-butter, milk, tea, and sugar exclusively; no vegetables except potatoes, and no meat, either salt or fresh. Although put upon suitable diet and given appropriate treatment, the patient died on the fifth day after admission. At the necropsy hæmorrhagic infarcts were found to be present in both lungs, and a large blood clot in the right temporo-sphenoidal lobe of the brain. Although scurvy is not a rare disease in this country, being frequently seen among navvies, especially among the Italians, it is rare to meet with a case coming from the part of the country where this patient worked, and in the class to which he belonged.

The proposed amendments to the Medical Act in this province are not meeting with the unanimous approval of the profession.

The addition of philosophy, intellectual and moral, to the list of subjects to be passed at the preliminary examination, was secured by the French representatives on the Council of the College of Physicians and Surgeons; and as philosophy is taught in most French schools and colleges, while it is not in English schools (I refer, of course, to schools in the province of Quebec), the result will be that an English student going into medicine will have to secure the services of a private tutor to prepare him for the preliminary examination. The general feeling seems to be that the matriculation or preliminary examinations were already as stringent as there was any necessity for, while the final or professional examinations could with advantage be rendered more severe.

It is announced, and the announcement gives a great deal of satisfaction, that the Governor-General and Lady Lansdowne will spend a considerable part of this winter in Montreal. Although the commercial metropolis of the Dominion, Montreal has hitherto seen very little of our several vice-regal governors, and the approaching visit of the Marquis of Lansdowne is taken as a happy augury for the future.

The recent death of Dr. J. M. Drake has deprived the community of a successful practitioner and the medical faculty of McGill College of an earnest coadjutor. Dr. Drake came to this country from London, Eng., thirty years ago, and after obtaining his medical education at McGill College, became house-surgeon to the Montreal General Hospital, and subsequently Professor of Physiology in McGill College, which post he held till succeeded by Dr. Osler some years ago. Although his career has terminated at the early age of fifty-nine, he had a large practice until the death of his wife, which occurred a few years ago, and which was such a blow to him that he gave up active work and retired to his country residence at Abbotsford, where he ended his days, regretted by all who knew him.

It is expected that at the next meeting of the governors of the Montreal General Hospital to be held in February, the plans for the new and much-needed hospital buildings will be submitted, and the work probably commenced next spring. The Civic Small-pox Hospital is nearly completed, and will be ready for use about April next should there be occasion for it. At present the city is free from small-pox, though typhoid fever and diphtheria are rather prevalent.

The annual flooding of the lower-lying parts of the town (caused by the blocking of the river below the city by the ice-bridge), with the sickness and pecuniary loss attendant, has again occurred, and though efforts are made to keep the sewers empty by means of pumps, they are only partially successful, and one may look for sickness due to this cause until the Dominion Government takes it in hand.

Montreal, Jan. 12th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Professor Anthony Alfred Bowlby, F.R.C.S. Eng., will deliver a course of three lectures on "Injuries of Nerves, their Pathology, Symptoms, and Treatment," on Wednesday, Friday, and Monday, March 2nd, 4th, and 7th. Students are admitted to these lectures on the introduction of a Fellow or Member of the College. The lectures will commence at 4 o'cook each day.

MEDICAL NOTES IN PARLIAMENT.

Lunacy Acts Amendment Bill.

ON the 21st inst. the House of Lords went into Committee on this Bill. In Clause 3 Lord Grimthorpe proposed an amendment to modify the preliminaries prescribed in the clause as necessary to be carried out before the friends of a lunatic could obtain a magisterial order for placing him under restraint. Lord Selborne was of opinion that the preliminaries would cause such delay as either to lead to lunatics being left at large until their lunacy was no longer curable, or to drive the friends of lunatics to resort in all cases to urgency orders for placing the lunatics under restraint. Lord Herschell was of the same opinion. The Lord Chancellor, admitting the force of the objections to the clause, promised to modify its machinery if its principle—the right of every alleged lunatic to have a judicial examination of his case before his liberty was taken away—were agreed to by their lordships. The amendment was ultimately withdrawn, and the clause was postponed. The remaining clauses were agreed to, with some slight alterations, and the Bill passed through Committee.

The Sanitary Registration of Buildings.

In the House of Commons on the 21st inst., a Bill brought in by Mr. Lacaita, to provide for the sanitary registration of buildings, was read a first time.

The Vaccination Act.

Mr. Picton gave notice of his intention to move, on the 21st prox., a resolution in favour of the repeal of the compulsory clauses of the Vaccination Act.

Obituary.

THOMAS FRASER, M.A., M.B., C.M. ED.

WITH regret we have to announce the untimely death of this young and promising physician, at the early age of twenty-six. Recent graduates of the Edinburgh School will remember his genial manner and the conscientious thoroughness of his work as a resident physician in the Royal Infirmary, and latterly as assistant to Professor Chiene. He left Edinburgh for a voyage in the East twelve months ago on account of failing health, but returned to Scotland recently and obtained the appointment of assistant-physician at the Crichton Institute, Dumfries. There his sudden death, which took place on the 15th inst. from diabetic coma, has occasioned deep regret; and it is pleasant to learn that his friends in and around Dumfries have decided to raise a memorial stone that may keep fresh the memory of his bright and useful life in that town. The remains were removed to Edinburgh, where the final tribute of affection and respect was paid by his sorrowing friends on Saturday last.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on the 17th inst.:—

Bindley, Robert Alfred, M.R.C.S., Highbury-hill.
Dane, Robert, Finchley-road, Hampstead.
Dansan, William, M.D. Toronto, Horwood-avenue, Toronto.
Jamieson, Archibald, M.D. Kingston, Ontario, Spark-street, Ontario, Canada.
Owen, John Vaughan, M.R.C.S., Machynlleth.
Ozzard, Alberht Tronson, M.R.C.S., Southsea.
Wolfe, Robert Inglewood, Ardsley, near Wakefield.

THE annual meeting of subscribers to the Macclesfield Infirmary was held on the 17th inst. In the report the financial condition of the charity was described as satisfactory.

LONDON HOSPITAL.—The annual dinner of the students of the London Hospital is, we learn, to take place on Tuesday next, at 7.30 P.M., at the London Tavern. Tickets can be obtained from C. L. S. James or L. Wainwright, the hon. secs. to the Dinner Committee.

H.R.H. THE DUKE OF CAMBRIDGE has consented to preside at a festival on May 6th to commemorate the twentieth anniversary of the Victoria Hospital for Children.

THE annual banquet of the Newcastle-on-Tyne Clinical Society was held on the 17th inst., Dr. Oliver, the president, in the chair.

DR. G. A. MAYER of Binghampton, New York, while setting a fractured arm, suddenly paused while pulling vigorously at the injured member and fell back dead. Apoplexy is believed to have been the cause of his death.

THE twenty-third annual collections in aid of the funds of the Sunderland Infirmary were made in the various places of worship in that town on the 20th inst.

VACCINATION GRANT.—Samuel Evans, L.R.C.P. (Lond.) M.R.C.S., &c., of Harwich, Essex, has obtained a Government grant for the efficient performance of public vaccination in the first and second districts of the Tendring Union.

THE first annual ball in aid of the funds of the Nottingham Samaritan Hospital for Women was held on the 17th inst., and, being largely attended, proved a decided success.

AN inquiry was opened on the 23rd inst. by Mr. S. J. Smith, Local Government Board inspector at West Cowes, relative to an application from the Local Board of Health to borrow £18,021 for sewerage works and £700 for increasing the water-supply. The inquiry was ultimately adjourned to the 19th prox.

THE third annual general meeting of the subscribers to the Blackheath and Charlton Cottage Hospital was held on the 5th inst., when satisfactory financial and general reports were presented and adopted.

THE ENGLISH CONJOINT BOARD.—On and after Monday, March 14th next, all applications relating to the diplomas of the Royal College of Physicians of London and the Royal College of Surgeons of England, under the old regulations, as well as under those of the Examining Board, must be addressed to Mr. Frederic G. Hallett, Examination Hall, Victoria Embankment, London, W.C.

AT a meeting of the Court of Governors of the University College of South Wales and Monmouthshire, Cardiff, on the 16th inst, a further appeal to the treasury for funds for the establishment of schools of medicine and engineering was advocated.

EXETER DISPENSARY.—The annual meeting of the supporters of this institution, which was founded in 1818, was held on the 12th inst. The report stated that 5513 persons were treated during last year, as against 5206 during 1885. Since the opening of the institution 202,456 patients have been treated. The treasurer's account showed that there was a balance in the bank of £391.

SUSSEX COUNTY HOSPITAL.—The annual general Court of Governors of this institution was held on the 16th inst., when it was reported that during the past year the number of in-patients had been 171; of out-patients, 6143; and of casuals, 1558. The receipts during the year, including legacies, were £9943, as against £12,019 in 1885. The expenditure was £10,426, as against £10,790. It was resolved that a new mortuary be erected, at a cost not exceeding £500.

GREENOCK INFIRMARY.—At the annual meeting in connexion with this institution, on the 17th inst., it was reported that the ordinary income for the past year was £4082, as against £4297 in the previous twelve months. The ordinary expenditure amounted to £4944, as against £4719. The total number of patients admitted to the infirmary during the year was 863, as against 879. Earnest appeals for increased support were made.

PERILS OF RURAL PRACTICE.—A French rural practitioner, Dr. Pierre Seguin, driving home one evening lately, was thrown out of the carriage and killed instantaneously by the shying of his horse. In the address of condolence drawn up by the Association of Medical Practitioners in the Gironde, attention is called to the dangers to which country doctors are exposed, just as sailors who have to brave the perils of the ocean.

Digitized by Google

OWING to the recent prosecutions of tradespeople for selling pepper adulterated with pepperette it is announced that the manufacture of this substance at Leghorn has been discontinued, and that its importation in England has ceased.

AT the recent annual meeting of the governors of the Blackburn and East Lancashire Infirmary it was decided not to alter the rule which prohibits the election of a junior house-surgeon to the institution.

THE ANTHRAX EPIDEMIC. — Mr. Whisken, the veterinary surgeon who made the post-mortem examination of the diseased cattle at Chignal, lies in a dangerous condition in Chelmsford Hospital. Two butchers also are reported to be suffering, and the horse which drew the carcases has died.

UNIVERSITY COLLEGE HOSPITAL.—Lady Jessel has recently paid into the bankers of this hospital a donation of £2000 for the permanent endowment of a bed in the institution to be called the "George Jessel" bed. The Right Hon. G. J. Goschen, M.P., has consented to preside at the festival dinner in aid of the funds of the charity to be held on April 27th.

THE BRITISH MEDICAL TEMPERANCE ASSOCIATION.—This Association held a meeting in the rooms of the Medical Society of London on the 18th inst. Dr. Walter Pearce, B.Sc., read a paper on the Absolute and Differential Diagnosis of Alcoholic Paralysis. In the discussion which followed, Dr. Richardson called attention to the fact that in past times cases of alcoholic paralysis had often been regarded as lead poisoning. He considered that the change which took place in the nervous system, as the cause of the symptoms must be of the nature of pectous change of the fluid nerve substance or of the membranous expanses leading to imperfect dialysis. Dr. Norman Kerr then called attention to the very great decrease of the amount of alcohol consumed in workhouses. He considered that there was still room for a greater reduction. In the discussion which followed Drs. Hall, Drysdale, Gray, Ridge, and others took part.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BOLTON, R. C. E., M.B., B.Ch.Dub., has been appointed Medical Officer for the Sixth District of the Lincoln Union.

COOMBE, ROBERT G., has been appointed Medical Officer for the Southminster District of the Maldon Union.

EMPSON, JOHN, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Milborne Port District of the Wincanton Union.

FOX, E. L., M.A., M.B., B.C.Cantab., M.R.C.S., has been appointed Assistant House-Surgeon to the Liverpool Children's Infirmary.

GRENFELL, HENRY OSBORNE, M.R.C.S., L.R.C.P.Lond., L.S.A., has been appointed Assistant Medical Officer to the Wandsworth Union Infirmary, vice H. T. Corbould, resigned.

HOBBES, THOMAS G. F. R., L.F.P.S.Glas., L.S.A., has been appointed Medical Officer for the Sutton Coldfield District of the Aston Union.

HOWNSELL, F. C. W., C.M.Cantab., M.R.C.S., L.S.A., has been appointed Resident Clinical Assistant to St. Marylebone Infirmary, Notting-hill, W.

LARDER, HERBERT, M.R.C.S., L.S.A., has been appointed Medical Officer for the Infirmary and the Workhouse of the Whitechapel Union.

LOCK, JOHN G., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Third District of the Pembroke Union.

PEARCE, JOHN P., M.R.C.S., L.S.A., has been appointed Medical Officer for the Second Division of the Third District of the Newhaven Union.

ROBERTSON, ROBERT, M.D.Ed., L.R.C.S., has been appointed Visiting Medical Officer to the Netherfield-road Hospital for Infectious Diseases, Liverpool.

SYERS, W. HENRY, M.D., M.R.C.P.Lond., has been appointed Assistant Physician and Registrar to the Hospital for Epilepsy and Paralysis, Regent's-park.

TAYLOR, ALFRED ERNEST, M.R.C.S., has been appointed House-Surgeon to the East Suffolk and Ipswich Hospital, vice Kitching, resigned.

THOM, G., M.R.C.S., L.S.A., has been elected a Surgeon to the Royal Albert Hospital, Devonport.

TYRRELL, EDWARD MUNRO, M.B.Edin., has been appointed Assistant Medical Officer to the Counties Asylum, Carlisle, vice T. D. Greenlees, M.B., resigned.

YARROW, G. E., M.D., L.R.C.P.Lond., &c., has been elected Surgeon-Accoucheur to the City of London Lying-in Hospital, vice P. L. Burchell, M.B., resigned.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ASHTON-UNDER-LYNE DISTRICT INFIRMARY. — House-Surgeon. Salary £30, with board and residence.

BIRMINGHAM AND MIDLAND EYE HOSPITAL. — House-Surgeon. Salary £100 per annum, with apartments, board, and attendance.

BOSCOMBE PROVIDENT INFIRMARY, Bournemouth.—Resident Medical Officer. Salary £60 per annum, with board, lodging, &c.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W. — Resident Medical Officer. Salary £80 per annum, with board and residence.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Pathologist.

GENERAL HOSPITAL, Nottingham.—Junior Resident Medical Officer. Salary £100 for first year, with an addition of £10 a year up to £120, with board, residence, and washing.

GLAMORGANSHIRE AND MONMOUTH INFIRMARY AND DISPENSARY, Cardiff.—Ophthalmic Surgeon.

HOSPITAL FOR WOMEN, Soho-square, W.—Clinical Assistants. Fee for course of three months, £5 5s.

INFIRMARY FOR CONSUMPTION, Margaret-street, Cavendish-square, W.—A Physician-in-Ordinary; three Visiting Physicians; and a Surgeon.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Laryngologist.

NORTH-WEST LONDON HOSPITAL, Kentish-town-road. — Assistant Physician.

OWENS COLLEGE, Manchester.—Senior Demonstrator in Physiology. Stipend £150 per annum.

PADDINGTON WORKHOUSE INFIRMARY. — Assistant Medical Superintendent and Dispenser. Salary £100 per annum, with board, lodging, and washing.

UNIVERSITY OF GLASGOW.—Examiners in Medicine.

WEST HERTS INFIRMARY, Hemel Hempstead. — House-Surgeon and Dispenser; to also act as Assistant Secretary. Salary £100 per annum, with board, furnished rooms, fire, lights, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

ELLIOTT.—On the 17th inst., at Monson-place, Tunbridge Wells, the wife of Thomas Elliott, M.D., of a son.

GARDNER.—On the 19th inst., at Clifton, the widow of Edward Barton Gardner, Surgeon-Major, I.M.S., late Civil Surgeon, Bareilly, N.W.P., of a daughter.

MACCOMBIE.—On the 17th inst., at the South-Eastern Hospital, New Cross, the wife of John MacCombie, M.D., of a daughter.

PLETTS.—On the 19th inst., at Wyndham House, Ryde, Isle of Wight, the wife of J. Menham Pletts, M.D., of a daughter.

SMITH.—On the 15th inst., at The Acacias, Upper Clapton, the wife of Gerard Smith, M.R.C.S., of a son.

YEO.—On the 18th inst., at Staines, the wife of Gerard F. Yeo, M.D. (prematurely), of twin boys, one still-born.

MARRIAGES.

HADAWAY—MOORLEY.—On the 22nd inst., at St. James's, Westgate-on-Sea, by the Rev. Geo. Collis, Vicar, Dr. James Hadaway, of Dent-de-Lion Villa, Westgate-on-Sea, to Eliza, widow of the late C. Moorley. No cards.

JAMES—DRIFFIELD.—On the 17th inst., at the Parish Church, Prescot, David James, M.D.Ed., to Letitia Kemball, youngest daughter of the late Walter Wren Driffield, Solicitor, of Liverpool and Prescot.

MYLES—WHITSON.—On the 23rd inst., at 15, York-place, Edinburgh, by the Rev. Armstrong Black, of Edinburgh, assisted by the Rev. John Kemp Bruce, of Peterhead, brother-in-law of the bride, Thomas Patrick Myles, of Brechin, N.B., M.B., C.M.Edin., to Euphemia Grace, youngest daughter of the late Jas. Whitson, Esq., of Isla-park, Coupar Angus, N.B. At home March 3rd. No cards.

WALKER—BROWNE.—On the 17th inst., at St. Luke's, Shire Oaks, by the Rev. H. T. Slodden, Vicar of Worksop, Hunter Urquhart Walker, L.M., L.R.C.P.Ed., L.R.C.S.Ed., eldest son of the Rev. Alexander Walker, of Rescobie, Forfar, N.B., late Senior Chaplain on H.M.'s Indian Establishment, to Ethel Mary, eldest daughter of the Rev. G. Osborne Browne, Vicar, of Shire Oaks.

DEATHS.

FORSYTH.—On the 18th inst., at 12, Park-place, Maze-hill, Greenwich, Katherine, wife of Alexander Forsyth, M.D.

HACKNEY.—On the 19th inst., at Twickenham, John Hackney, M.R.C.S., L.S.A., aged 72.

LINDSAY.—On the 21st inst., at Mickleover, Derby, J. Wallace Lindsay, eldest son of J. Murray Lindsay, M.D., aged 22.

MOCKLER. — On the 17th inst., at Oxford-terrace, Hyde-park, Edward Mockler, formerly Surgeon, Queen's Bays and 17th Lancers, aged 77.

RITCHIE.—On the 15th inst., suddenly, at Liverpool, William Barry Ritchie, M.D., J.P., of Belfast, in his 71st year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, February 28.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Mr. W. Y. Dent: Building Materials (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Dr. Robinson: Excision of Hip in Adult.—Mr. Lennox Browne: (1) Case of Excision of half the Larynx; (2) Faucial and Pharyngeal Tuberculosis.—Mr. Pick: Displacement of Head of Femur after Fever.—Mr. Bourne: Ichthyosis Hystrix.—Mr. Black: Trephining for Supposed Abscess of Brain.

Tuesday, March 1.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Respiration.
SOCIETY OF ARTS.—8 P.M. Mr. Edward Cunliffe-Owen: The Colonial and Indian Exhibition.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Annual Meeting. Address by the President. Election of Officers and Council.

Wednesday, March .

MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Inaugural Address by the President (Dr. John Williams). Adjourned Discussion on Dr. Gibbons' paper on Unilateral Galactorrhœa.—Dr. Champneys: On the Separation of the Placenta.
SOCIETY OF ARTS.—8 P.M. Mr. H. J. Beale: The Cultivation of Tobacco in England.

Thursday, March 3.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Godlee: Adeno-sarcoma of Tongue with Calcifying Nodule in Centre.—Mr. G. R. Turner: Alveolar Sarcoma growing from the Lumbar Spine.—Dr. N. Moore: Malarial Diseases of Liver and Spleen.—Mr. Lawson Tait: On the Pathology of Extra-uterine Pregnancy.—Mr. Barwell: Cirsoid Aneurysm of the whole of Left Upper Extremity.—Dr. Price: Cholesteatoma at Base of Brain.—Mr. Fenwick: Metastatic Carcinoma of Prostate.—Mr. A. Doran: Fibroma of the Ovarian Ligament. Card Specimens:—Mr. Gould: (1) Portion of Cervical Vertebræ expectorated from a case of Retro-pharyngeal Abscess; (2) Old Excision of Knee-joint.—Mr. D'Arcy Power: A Ithinolith.—Mr. Shattock: Colles' Fracture with Forward Displacement of Lower Fragment.—Mr. A. Doran: Horny Growth from the Neck.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Edmund Gosse: The Critics of the Age of Anne.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. Mitchell Banks (Liverpool): Extirpation of the Axillary Glands a Necessary Accompaniment of Removal of the Breast for Cancer.—Dr. W. H. Day: Habitual Constipation in Children, and the Methods of Treatment.

Friday, March 4

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF ARTS.—8 P.M. Major-General Sir F. J. Goldsmid: Our Trade Routes to the East.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Card Specimens:—Mr. H. Percy Dunn: (1) An Aneurysm of the Thoracic—extending into the Abdominal—Aorta; (2) Epithelioma of the Œsophagus.—Dr. P. S. Abraham: Microscopical Sections of the Cervical Cord and Sympathetic Ganglia in a case of Exophthalmic Goitre. Living Specimens:—Dr. Scanes Spicer: A series of cases of Diseases of the Naso-pharynx. Papers:—Dr. J. B. Ball: Nocturnal Incontinence of Urine.—Mr. R. Fitzroy Benham: Impacted Urethral Calculus, Perineal Section, Recovery.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Mr. Victor Horsley: Brain Surgery in the Stone Ages.

Saturday, March 5.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. The Right Hon. Lord Rayleigh: On Sound.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE COLD AFFUSION IN HEADACHE.

W. F. P.—Sir Robert Christison, in his "Autobiography," bears emphatic witness to the efficacy of this treatment, citing in particular the case of his own mother, who suffered from headache of a peculiarly persistent character, and who cured herself effectually by the cold douche. It was the favourite remedy of the Romans, as may be inferred from more than one passage in the judicious compilation of Celsus: "Capiti nihil æque prodest atque aqua frigida" (Nothing is so beneficial to the head as cold water), Lib. i., c. 4. Again (Lib. i., c. 5), when touching on the various inflammatory affections of the head and its cavities, he says: "Usus aquæ frigidæ prodest iis etiam quos assidue lippitudines gravedo, destillationes, tonsillæque male habent" (The cold affusion is of benefit to those also who suffer from chronic ophthalmia, from cold in the head, from catarrh, and from inflamed tonsils). Again, the lassitude and headache induced by the scirocco (*auster*), to which the British resident on the Mediterranean is so subject, and which no amount of acclimatisation seems to lessen, has its appropriate remedy in cold water: "Præcipue omnibus eo auxiliis utendum est ubi gravius cælum austri reddiderunt" (This remedy is of especial advantage to all when the atmosphere has become heavy by the scirocco), Lib. i., c. 5.

M. O. H.—We do not think that the medical officer of health should make inquiries in all cases through the medical attendant. Such limitation would make his work impossible, if always enforced; but undoubtedly he would be more likely to accomplish his object if he were to adopt a conciliatory conduct both towards the patient and the medical attendant.

Stand Sure.—Be true to your synonym, and assume that everyone knows that you are not the discredited practitioner.

W. McC.—1. Yes.—2. No.—3. They are bound to provide an applicant with some sort of accommodation.

SIR JAMES HANNEN'S COURT AND THE NEWSPAPER PRESS.

To the Editors of THE LANCET.

SIRS,—May I venture to suggest that the members of the medical profession memorialise the Lord Chancellor, or whoever may be the proper authority, to adopt measures whereby the wives and daughters of all decent citizens may be able to read the newspapers without having presented such shameful evidence as has recently outraged public decency by being reported at some length and in some detail in the columns of our daily and other journals.

I am, Sirs, your obedient servant,

Grove-road, N.W., Feb. 22nd, 1887. NORMAN KERR, M.D.

A CONGENIAL CLIMATE FOR ANGLO-INDIANS.

IN reply to a query inserted in our last number on the above subject, "*A Brigade-Surgeon* writes:—"I will venture the statement that "J." will not have much to complain of on the score of the cold of English winters. I have myself been twenty years in India, and have now been home several winters; but I have seldom to put on a great coat, and am almost surprised to hear so many complain of the cold. Further, I feel the heat of a hot summer's day a great deal more than I did before I went to India, and more than a native of these isles who has never been in the tropics. My own theory is that the malaria which accumulates in a person in India and remains in his system renders him insensitive to cold and very sensitive to heat."—"*An Old Indian*" recommends Southport, Lancashire, as a spot possessing a mild and equable temperature, and where living is cheap. Another correspondent, who has spent three winters at Tenby, Pembrokeshire, thinks "that is just the place for people who have lived in India." A fourth recommends Flushing on the shore of Falmouth harbour. A fifth writer speaks of Bournemouth as possessing all the qualities likely to meet the wants of an Anglo-Indian. A sixth has no doubt of the superior advantages of Bonchurch, Isle of Wight, for the same purpose. Whilst a seventh correspondent gives glowing accounts of the climate of Queenstown.

H. N. (Colchester).—The "Acque Catulliane." They were discovered in 1784 by the well-known naturalist, Giovanni Catullo, on the Monte Civillina, in the Venetian territory. On analysis they were found to be ferro-arsenical, and are in high repute among Italian physicians for their tonic and alterative virtues. Italy abounds in such mineral resources; but, unlike France, Germany, Austria, and Switzerland, she has hitherto been lacking in the enterprise which establishes well-appointed hotels in their neighbourhood under competent medical surveillance.

Dr. C. Bell Taylor (Nottingham).—Yes, in as early a number as possible.

DAMP BEDS.

To the Editors of THE LANCET.

SIRS,—Your note on this grievance, and the desire for a remedy on the part of your correspondent, "Traveller," reminds me of an anecdote I heard some time since of a commercial nomad, who, having retired to rest, became unpleasantly conscious that his bedclothing was anything but properly aired. He jumped up in a rage, stuffed the offending sheets up the chimney, and rolled himself in the blankets. Some twelve months afterwards his travels brought him to the same hotel. When shown up to his room, the chamber-maid examined him rather closely, and then said: "Dear me, sir, you *are* the same gentleman. Do you know, a most curious thing happened when you were here last." "What was that?" he exclaimed. "Why," she said, "the sheets disappeared, and we could not think what became of them." "Oh, indeed," he replied. "Then get me my bill directly; you've not had a fire in this room since, or you would have found your sheets—where all damp linen ought to be—stuck up the chimney!" Possibly, if fellow-sufferers revenged themselves in similar fashion, hotel-keepers would take better precautionary measures for insuring their guests' health and safety.

I am, Sirs, yours truly,

Walton-on-the-Naze, Feb. 21st, 1887. HENRY GRAMSHAW.

To the Editors of THE LANCET.

SIRS,—Your correspondent "Traveller" seeks a plan of safety when compelled to occupy a bed which may be damp. Let him always be provided with a waterproof sheet (a nicely made one will not take up much room in a portmanteau), place this on the bed with two blankets over it, discard the sheets, and use two or three blankets over him, according to weather, and he will be safe. I have repeatedly been thanked for this information by patients who are constantly on travel.

I am, Sirs, yours faithfully,

Kidderminster, Feb. 19th, 1887. S. STRETTON, M.R.C.S.

THE MARGARET-STREET CONSUMPTION INFIRMARY.

Dr. R. E. Dudgeon, in a somewhat lengthy communication, writes that the terms of his amendment to the Rev. M. R. Mowll's resolution were as follows: "That any attempt to limit the liberty of opinion or practice of the medical officers is not sanctioned by the laws of the infirmary, is prejudicial to the interests of the infirmary and its patients, and is opposed to the spirit of the Medical Act of 1858." Dr. Dudgeon remarks: "The medical men who voted in the minority, and, indeed, the whole medical profession, should be much obliged to me for this effort to uphold the freedom and dignity of the profession, and to prevent the right of private judgment in therapeutics of the medical officers of a public infirmary being interfered with by a set of non-medical members of an executive committee, who know nothing at all about medical theories or practice."

Mr. Friend (Brighton).—We are not aware. But the work could no doubt be obtained by order of any medical bookseller.

SEA-SICKNESS.

Mr. Whittingdale states that while acting as surgeon to the Peninsular and Oriental Steam Navigation Company, he tried at different times most of the remedies recommended for sea-sickness, such as bromide of sodium, cocaine, nitrite of amyl, &c., with very unsatisfactory results. The following method, based on the treatment of chloroform sickness, however, proved most successful. A tumbler of tepid water is first administered to the patient. This, of course, is generally quickly returned, but soothes the stomach. Then a warm mustard and linseed poultice, in the proportion of one part of mustard to two of linseed, is applied to the epigastric region, and the following draught given a quarter of an hour after the tepid water:—Chloral hydrate, twenty grains; simple syrup, one drachm; water, to an ounce. If this be rejected, our correspondent begins *de novo* with the tepid water and repeats the draught. After the draught has been taken and retained, the patient is ordered to lie in his berth, and sleep usually follows. On waking the swimming in the head and nausea have disappeared, and he is able to go on deck.—*Mr. H. Wakefield* considers that anyone who has seen much of this malady can hardly doubt that its origin is mental, and in a large majority of cases the imagination is the source of trouble—for instance, he has seen on several occasions ladies suffering from sea-sickness before the ship has left its moorings in the dock, where there is not the least sign of motion. Iced stimulants and the recumbent posture are remedies which he now employs after a careful trial of all the so-called specifics extending over a period of six years.—*Mr. J. R. Stocker*, of Liverpool, refers to a paper of his in THE LANCET of Dec. 17th, 1881, in which he suggested a somewhat similar cause of sea-sickness to that suggested by Dr. Thurstan. "I may take this opportunity of stating," says Mr. Stocker, "that in describing the physiological conditions concerned in its production, I unfortunately omitted to mention a very important matter—viz., the spasmodic closure of the glottis, which occurs when the vessel falls; this is a matter of common experience, and is popularly expressed as 'catching the breath.'"

Doubtful.—The dietetic treatment of gout is a matter in which professional opinion is still at variance. There are two extreme schools to discriminate between, those who may be termed the "ascetics" and those who advocate the tonic treatment of the disease; whilst a few hold to the golden mean, and adhere to rules originally laid down by Sydenham. Some teachers prohibit meat, others allow it; some prohibit sugar, others say it is not injurious; some forbid fat, others say it is the only constituent that may be freely used.

Climate.—Spencer Thomson's "Health Resorts of Britain" would probably answer the purpose.

G. M. P.—The case is not a very uncommon one.

TRANSPORT OF INFECTIOUS PATIENTS.

To the Editors of THE LANCET.

SIRS,—I was much surprised to find in THE LANCET of Jan. 29th, page 235, a paragraph proposing the use of particular vehicles—to the exclusion of all others—for the transport of infectious patients. I thought that this custom had long been prevalent in London, as it is in many other towns—e.g., in Berlin, and will soon also be adopted in Dresden. To prove the urgency of adopting this measure, allow me to mention a case which took place in Dresden some time ago. A gentleman happened to drive in a cab, which had been used a short time previously for the transport of a patient attacked by small-pox. The gentleman soon after took the same disease, and could only have caught the infection through using the cab, as his was the only case of small-pox in the town at that time. A similar case is mentioned by Dr. Ollivier in Paris with regard to diphtheria. It is my firm belief that cabs, trams, railway-carriages, &c., are among the chief means of spreading infection, and it is high time that the sanitary authorities should take the matter into serious consideration, and prevent further mischief by providing ambulances for the transport of infectious patients, to the exclusion of all other vehicles.

I am, Sirs, yours truly,

Dresden, Feb. 15th, 1887. DR. MED. ARTHUR BERTHOLD.

THE ASTROP PROCESS.

WE are asked to add to our recent statement concerning the Astrop process of fluid depuration which is now carried on at Walthamstow that Mr. Astrop does not recommend the use of lime, upon which the sanitary authority of that place insist for the precipitation of sewage. The intention of the authority is to retain in the effluent, for use on their land, all matter of manurial value. The desire of Mr. Astrop is to retain this matter in the sludge, whence it would remain in the poudrette which is manufactured by his process.

Mr. A. F. Mickle, M.B.—The result of previous attempts to found medical clubs is not of a kind to afford much hope of success for fresh efforts in the same direction.

H. (Brighton).—The letter is too long for insertion.

MYOPIA IN SCHOOLS.

AN examination of the condition of the eyes amongst the young people frequenting some of the more important schools in Stockholm, carried out by Dr. Widmark, showed that at the age of from six to eight there was no myopia; at nine, however, though the girls were still nearly free from it, 14 per cent. of the boys were slightly, though distinctly, myopic. This difference is said to be accounted for by the examination which boys have to pass on admission to a secondary school, which obliges them to work more in the preparatory school. After this age myopia in the two sexes goes on increasing, until at sixteen, when girls usually leave school, the percentage amongst them is thirty-three, the mean degree of myopia being 2·5 dioptrics. At this age the percentage of myopia amongst the boys is 39, and the mean amount two dioptrics. Later on, amongst advanced pupils the myopia was much more common and more marked amongst the girls, which Dr. Widmark thinks is to be accounted for partly by the delicacy of the sex, but mainly by the great inferiority of physical education and opportunities for out-door games in girls' schools, and by the needle-work and music which are there so frequently the employment of out-of-school hours.

Mr. Robottom is referred to an article on the subject in our last issue, page 387.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—Although appeals for professional help are unfortunately but too common, the sympathy of some members of the profession may, I am sure, be solicited on behalf of an elderly medical man—Mr. C. H. Huxley—who was injured in a railway accident nearly three years ago, and has since been unable to support his wife and children. He sustained an injury to the hip-joint, and chronic arthritic changes resulted, so that his powers of walking are very limited, and he is unable to attend to ordinary professional work. Very small damages—only £50—were given at the railway trial, and he is now in a destitute condition. Professor Erichsen fully concurred with me as to the nature and extent of the articular changes. Subscriptions will be received by me at the address given below. I am, Sirs, your obedient servant,

5, Henrietta-st., Cavendish-sq., W., Feb. 21st, 1887. WM. ADAMS.

OPHTHALMIC AND AURAL PRACTICE ABROAD.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to ask your readers for information as to openings for ophthalmic and aural surgeons abroad, especially in the colonies? I am, Sirs, yours faithfully,

Feb. 18th, 1887. J.

Dr. Thursfield's communication is unavoidably held over till next week.

Mr. J. Rand.—The lines are rather too political for our columns.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Norman Kerr, London; Mr. Cavendish Bentinck, London; Dr. Colcott Fox, London; Dr. F. Warner, London; Mons. Masson, Paris; Dr. Burney Yeo, London; Dr. Lambert, Liverpool; Dr. Glanville; Mr. Simeon Snell, Sheffield; Dr. W. Hunter, Edinburgh; Dr. R. Macdonald, M.P., London; Mr. Barwell, London; Mr. Seaton-Cockell; Mr. Buckston Browne, London; Dr. Jos. Rogers, London; Mr. J. A. Jones; Dr. A. Berthold, Dresden; Dr. Jas. Lectures
ON THE
SURGICAL TREATMENT OF PULMONARY CAVITIES.

Delivered at the Consumption Hospital, Brompton,

By RICKMAN J. GODLEE, M.S., F.R.C.S.,
SURGEON TO THE HOSPITAL AND TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE I.

GENTLEMEN,—It may be hoped that the subject of the surgical treatment of pulmonary cavities is still in its infancy, and it may fairly be anticipated that whilst that of certain classes of cases will advance in efficiency, the treatment of others will again be handed over altogether to the physicians, although it is not yet obvious in what direction their efforts, if pursued, are likely to be more successful than heretofore. In some forms of pulmonary abscess surgical interference is obviously inadmissible; nothing, for instance, can be hoped from it in treating a lung which is riddled by numerous tubercular cavities or the multiplied gangrenous foci which occur in the course of embolic pyæmia. Those in which surgery has been, or may be, attempted, may be thus classified:—1. Tubercular cavities. 2. Cavities resulting from gangrene of the lung. 3. Cavities resulting from the bursting into the lung of abscesses or other collections of irritating matter from without. 4. Bronchiectases, from whatever cause arising, and including those which depend upon the presence of a foreign body in the air passages. Before giving an account of such cases as have come under my own observation, I propose to give a short *résumé*, not a complete history, of what has been done by others in this branch of surgery.

As long ago as 1726 Dr. (afterwards Sir) Edward Barry[1] of Dublin hints at the advisability of opening phthisical cavities in the following quaint way: "But when from the violence of the distemper, or the neglect of a proper method, the symptoms are so far increased as to carry a fatal aspect and elude the force of the most effectual medicines, instead of amusing the unhappy patient with false hope and the repeated use of palliative remedies, or denouncing certain death, it would be of the greatest use if a method could be proposed which, tho' dubious and painful in the operation, may give the afflicted some chance for their life: *Præstet anceps quam nullum experiri remedium.* Such a probable relief can only be expected by opening the breast where the most frequent pain and oppression direct the situation of the ulcer," &c. He then proceeds to say that the operation may be performed without danger because adhesions are sure to exist, and fortifies his argument by the account of a case which may or may not bear upon the subject. It was that of a man who received a sword-wound in the chest, which was allowed to heal rapidly externally. The cough, hectic fever, and purulent expectoration which followed were relieved by a timely opening up of the original wound. But this may of course have been merely a case of empyema. He concludes: "'Tis surprising that this method has not been frequently attempted, since it is founded on such plain and easie reasoning from anatomical observations, tho' I'm sensible that there are several obstacles that will always oppose it, &c. ..... But 'tis most certain that many phthisical persons may by this means be preserved that will otherwise unavoidably perish. If the operation be rightly performed there is great reason to expect success; neither if it fails can it be attended with any great danger or much contributs to hasten their fate." Whether Barry ever actually operated upon a genuine pulmonary abscess must, I think, remain doubtful; numerous cases are reported both here and in another work of his,[2] but I am sure that at all events a large number of these must have been cases of empyema. I cannot leave Edward Barry without quoting a few words about a popular belief at that time in the parasitic nature of phthisis, which at the present day of the bacillary rule sounds strangely prophetic. He says: "It has been observed that ulcers in the lungs and in other parts, when narrowly viewed with microscopes, are covered with several insects; from whence it has been concluded that they owed their origin to them, and by being inspired with the air, fixed their situation on the lungs, eroded and ulcerated them. From the same irregular way of reasoning, these animalcules have been by others supposed the cause of several distempers, and particularly such as are contagious." The whole quotation is quaint and interesting; but Barry's own opinion on the subject is difficult to gather, and, indeed, it is pretty clear that this was as indefinite as his knowledge was vague. He concludes his work on the three digestions with the following words: "This infinite number of animalcules which swarm in the air and on the surface of the earth seem to me to be of much greater use and importance than is generally imagined, as all stagnating animal and vegetable humours are quickly taken up by them, and receive a new life and regular circulation; and perhaps we owe our safety in some measure to this scarcely visible part of the creation, without which the atmosphere would in a short time become highly corrupted, and unfit to continue the life of other animals."

Before Barry's time it is said that Baglivi, in 1714, recommended the incision of pulmonary cavities, but I have not been able to find any reference to the subject in glancing through his long and discursive work.[3] And still older men than these had made incision into the chest in desperate cases, and with good result. Paschal, Paré, and Harvey have cases in point; and upon looking back into the dawn of medical history we must not forget the classical case recorded by Pliny,[4] when a soldier, given up by his doctors and sick of his heavy burden, sought death in the front of battle. Great must have been his wonder when the enemy's spear relieved his sufferings in a quite unexpected manner by opening his empyema. "Atque feliciter hoc vulnere sanatus est."

About the same time as Barry, two or three surgeons seem to have written on the subject. In Göttingen, in 1793, Gumprecht[5] devoted his doctorial thesis to a dissertation on abscess of the lung, in which he advocates the incision of pulmonary cavities; but the diagnosis at that time between pulmonary cavities and empyemata was so uncertain that we do not gain anything beyond the historical interest in perusing his work. At the end of it, however, is an interesting series of cases of wound of the lung, which well repays study. In Scotland, Benjamin Bell[6] in 1778 refers to the free incision of abscesses in the lungs and the drainage of them by means of lead tubes, making special reference to the importance of some arrangement for preventing the tube from slipping into the chest; but he seems to be referring altogether to abscesses which have resulted from the infliction of wounds, and not to those occurring spontaneously.

After this but little attention seems to have been directed to the matter until the middle of the present century; we then find that Dr. John Hastings,[7] fired by Barry's example, procured the help of his friend, Mr. Storks, to open two apparently genuine cases of tubercular apex cavities, one of which improved under the treatment, but the other, a woman of twenty-five years, in whom phthisis was far advanced at the time of the operation, died fourteen days afterwards. The account is to be found as an appendix to his work on the Treatment of Phthisis by Naphtha, and it includes a letter from Sir Henry Marsh detailing two cases supposed to be of tubercular cavities treated by him by incision about 1830; but as in both cases the matter was pointing, a certain amount of doubt must hang over the diagnosis. One recovered and the other died. Hastings says that a Welsh doctor named Thomas performed a similar operation about the same time. He recommends the use of a full-sized gum catheter with a perforated ivory cap, to which straps could be attached, and over which a piece of warm sponge was to be placed.

A few years later there appeared an interesting paper by Dr. Horace Green,[8] written in a somewhat combative spirit,

because the possibility of passing tubes through the glottis from the mouth had been denied by Erichsen and others. His treatment for both bronchiectatic and tubercular cavities consisted in passing a soft tube not only into the trachea, but, so he asserts, into one bronchus or the other as the case demanded, and injecting a drachm or more of an aqueous solution of nitrate of silver (thirty or forty grains to the ounce) into the dilated bronchi or the pulmonary cavity. The patients whose cases he recites appear generally to have been distinctly benefited, and, as is very remarkable, seem not to have suffered from a fit of coughing or other unpleasant symptom at the time the injection was made. Notwithstanding its apparent success, however, the treatment does not seem to have met with much favour, nor are his extremely categorical statements, it must be owned, quite convincing that the dose was not sometimes received into the stomach.

Quite another method of introducing fluids into phthisical cavities is suggested by Dr. F. Mosler of Greifswald.[9] He passed a fine trocar and cannula through the chest wall into the cavity, and then injected through the cannula a weak solution of permanganate of potash. Then in a later case he called in the help of Hüter, who made an incision into a large apical cavity. The incision was made at the upper border of the third rib, 5½ cm. from the sternum, and passed through firm pleural adhesions. The operation offered no difficulty, and caused no trouble from hæmorrhage. He subsequently injected weak perchloride of iron when some little bleeding had occurred, and at other times solutions of carbolic acid and permanganate of potash and tincture of iodine. The patient lived from July 2nd to Oct. 5th, and for a time seems to have markedly improved; the cough was much relieved, and the great albuminuria from which he suffered diminished. The albuminuria returned, however, and emaciation became great, and it is perhaps questionable how far life was prolonged, though comfort was, no doubt, given by means of the operation.

An almost precisely similar method of treating pulmonary cavities has been advocated in America by Pepper of Pennsylvania and Beverley Robinson of New York,[10] and in our own country this or some modification of it has been put in practice by Dr. Shingleton Smith and others.

Dr. Shingleton Smith[11] records five cases, two of which were of tubercular phthisis, one was of gangrene of the lung, one of chronic pneumonia, and one of chronic tubercular pleurisy. The phthisical patients seem to have improved somewhat under treatment, though one developed some pleurisy, which was possibly the result of the injection; the tubercular pleurisy case remained *in statu quo;* the other two cases died—not, however, apparently as a result of the injection. The method of proceeding is to introduce with a hypodermic syringe five minims of ether in which one grain of iodoform has been dissolved; the iodoform was at first dissolved in oil, but a fear of fat embolism led to the adoption of ether as a solvent. The injections were sometimes continued daily, sometimes less often. I do not think that these cases show much, except, as is stated by the authors, that the process does not appear to be a dangerous one. I can conceive that the introduction of iodoform might be useful in cases of bronchiectatic or gangrenous abscesses, though I think that a free incision into the latter, at all events, would be better treatment. As to the phthisical cavities, it seems most improbable that, even if iodoform be fatal to the tubercle bacillus, it could be made to diffuse itself sufficiently to reach further than the immediate vicinity of the cavity or the spot of solid lung into which the injection is introduced; if, therefore, it be of any service at all, it can, I conceive, only be in the direction of stopping the fetor of the expectoration from a vomica. This, then, does not appear a very promising line of treatment to pursue. If ever we do discover a drug which is a specific for destroying the active principle of tubercle, it is more likely that it will be efficient if administered internally than if any attempt be made to attack locally a mischief which is usually, at the period when such an attack would be thought advisable, very widely diffused throughout the organ.

An interesting summary of what has been done in the direction of pulmonary surgery will be found in a paper by Dr. de Cérenville of Lausanne.[12] He has himself treated surgically four cases of phthisical apex cavities with a different object from that pursued by others—viz., following Estlander's treatment for chronic empyema, to allow the chest walls to collapse on the cavity by removing portions of the ribs. These are his cases:—

1. F——, aged forty years, advanced phthisis with large cavity at left apex. Resection of the third rib to allow the chest wall to fall in. The patient lived little more than a fortnight. Some retraction is said to have occurred.

2. F——, aged fifteen. Advanced phthisis, with consolidation and excavation of the upper lobe of the left lung. Parts of the second and the third ribs were excised, and threads were passed through the pleura into the lung in order to ensure adhesions if these were not present. Four days later, an attempt to reach a large cavity resulted only in the discovery of a small one. The operation appears to have had but little influence on the progress of the disease. The patient died three weeks after the first operation.

3. F——, aged twenty-five. Advanced phthisis; cavities in the left upper lobe. Parts of the second and third ribs were removed, and a large cavity was opened. The cough and expectoration were very much relieved, and the cavity decidedly contracted; the patient living five weeks after the operation.

He has also operated on another case of which he does not give the notes. The results of these are interesting, but not very encouraging. The cases were obviously hopeless, however, and some temporary relief seems to have been gained in the third. At the Congress at Wiesbaden, 1883, the consensus of opinion (Mosler, Fenger, Hollister, &c.) seems to have been strongly against the opening of tubercular cavities, at least until a specific tubercular bacillicide can be found. De Cérenville agrees with this conclusion in the main, making, however, a possible exception in favour of cases where the cavity is single, the cough troublesome, and the mischief apparently localised. He allows, however, as is notorious, that the amount of mischief is likely to be greater than the physical signs indicate. As far as I can form an opinion without practical experience I am inclined to agree with de Cérenville, though I cannot help thinking that in a certain number of cases of single apex cavities with troublesome cough, not only might the symptoms be relieved, but the danger of transplanting the mischief into the other lung might be to some extent lessened.

A far more heroic method of dealing with tubercular lung has been in recent years suggested by certain Italian surgeons who have made this subject a specialty, though it has been followed up by some observers in Germany. Dr. Domenico Biondi showed first the possibility of an animal surviving the complete extirpation of a healthy lung,[13] and then proceeded to demonstrate that the same might be done in an animal the lung of which had previously been inoculated with some of the sputum of a tubercular patient, and had actually become the seat of tubercular changes.[14] A very considerable proportion of the animals (rabbits, cats, and dogs, twenty-one in all) died as the result of the first or the second operation, but some survived and lived for a very considerable time afterwards. The dogs and cats were not favourable subjects for the development of tuberculosis, but it is remarkable and interesting that in some of the rabbits tubercle was actually developed in the lung, which was removed, and after the removal the animal remained free from further development of the disease. The conclusion that the author wishes to draw is obvious, but he hardly ventures to hint at the application of the treatment to the human subject, and it can scarcely be suspected that it will ever be placed amongst the recognised surgical procedures. It could only be applied in the early stages of phthisis, when the disease may be considered within the possibility of a practically permanent cure by other and simpler means. And indeed the same may be said of another possible deduction—namely, the removal of tumours of the lung. Diagnosis must clearly reach a much greater pitch of refinement before the physician could counsel or the surgeon attempt the removal of a primary tumour of the lung, rare as it is, and difficult as it must always be to discover in its

Digitized by Google

earlier stages, when alone it could conceivably be extirpated.[15] It must, however, be stated that in two cases of phthisis parts of the lung have been actually removed by Ruggi, one of the patients dying in a few hours, and the other on the ninth day. And not only so, but tumours of the lung also have been removed, though it must be owned that the experience of the surgeons who undertook the operation is not very encouraging. Weinleicher, in 1882, removed a round tumour as large as a man's head from the thoracic wall of a man aged thirty-seven, leaving a huge gaping opening into the chest and taking away a part of the lung to which it was adherent; the patient died twenty-four hours afterwards. And Kroenleim also removed a recurrent sarcoma in the same situation from a girl, aged eighteen, taking away part of the sixth rib and some adherent lung. The end of this case is not reported in the interesting article of Albert's from which I take the reference.[16]

Lastly, to complete this branch of the subject, must be mentioned a method of treating tubular lung, whether containing cavities or not, introduced by Guérin in 1830, and more recently modified and extensively practised by Vidal—viz., the puncture by means of the actual cautery. Vidal reports forty-four cases, thirty-seven of whom improved under treatment; and I believe that this method has also been employed in Australia.

Gangrenous cavities.—It must be remembered that gangrene of the lung may follow wounds of the chest, and in the old days of duelling empyemata and pulmonary abscesses from such a cause seem to have been common. Now, however, this is not the case in civil practice. Gangrene of the lung is said also to be caused by the presence of a foreign body in the air passages; but as from the present point of view the dilatation of the bronchi, which I believe invariably follows, is the more important lesion, I shall discuss this question under the head of Bronchiectasis; and will pass on to gangrenous cavities resulting from some form of pneumonia. These cavities are perhaps the most promising with which the surgeon is called upon to deal, especially if operation be not too long delayed. In the course of time, if the patient survive, the surrounding lung becomes condensed and inelastic; but in the earlier stages of the disease it retains more or less its normal characters, and the walls of the cavity are able to fall together like those of an abscess in the soft parts elsewhere. But delay is often almost unavoidable on account of the great difficulty of localising the position of the cavity with precision, and the still greater difficulty of ascertaining the absence or the presence of adhesions. I do not think that the second point should be allowed to influence the surgeon in the direction of delay, and certainly should not interfere with an exploratory puncture, because, in the first place, experience shows that even adhesions which have been accurately diagnosed by the most competent observers may, after all, be found to have no existence, and, in the second place, it seems clear that exploration with an aspirator needle may be safely made through a patent pleura, even if the instrument pass into a collection of putrid pus. I do not say that mischief will never follow this procedure, and I am sure that it is wise to ascertain for certain the condition of the pleura before making a free incision into a lung containing septic pus, for if the non-adherent pleura be opened, and through it a drainage-tube be passed into a putrid cavity, very serious symptoms may result. This was well illustrated in a case of bronchiectasis (which will be referred to again), where we had ascertained a week or two previously that there was some clear fluid in what was thought to be merely a remnant of the pleural cavity. On cutting through the intercostal space, it was found that the two layers of the pleura had become adherent since the preliminary puncture, but only by very weak adhesions, which easily broke down under the pressure of the finger and the expiratory efforts of the patient whilst the opening was being made into the bronchiectatic cavity. This led to the opening up of a large remnant of the pleural sac, the walls of which were non-adherent, and the consequence was that the pus from the bronchiectasis escaping into the pleura set up a septic pleurisy, from which the patient nearly died.

[15] These experiments have also been carried out in Germany, by Th. Gluck, in 1881 (twenty cases, some successful removals of the entire lung). Dr. Hans Schmidt (three out of eight survived), and Dr. Block, in 1882 (fifty to sixty cases done without removal of rib).

[16] Ueber Lungen Chirurgie. Wien. Med. Presse, 1884, p. 887.

It will be well, therefore, to consider at the outset what should be done when these adhesions, so commonly but yet not invariably found, are wanting. One plan would be that mentioned above as recommended by De Cérenville as a precautionary measure—namely, to pass needles armed with silk through the pleura into the lung; but as in almost all cases the lung is solidified, and will therefore not fall away to any extent from the thoracic wall, even if no adhesions at all be present, I do not think that this, though quite unobjectionable, can be considered to be a necessary precaution. The right method of procedure, though I confess it is not a very easy one, is carefully to stitch the lung up to the opening which has been made in the chest walls. It is a difficult proceeding, because the parts are in a constant state of movement from the act of respiration, and because the lung itself is but ill suited to retain the stitches that are placed in it, and also because the hole in which the manœuvres have to be carried on is a rather deep one, and mostly obscured by the presence of blood. I have only once had to put this plan into practice, and though here it was only partially successful, it was sufficiently so to show that, with a little more care, the closure of the pleura might have been effected. We found, in this case, at the end of a few days, that a part of the stitching had given way, but as no cavity was reached, no evil consequences as regards the pleura resulted, the wound remaining aseptic. Of course, after the stitches have been placed, the attempt to open the cavity must be postponed for at least a week, and at the end of that time the instruments used must be sharp, and their employment gentle, lest the accident which it is intended to avoid may, after all, happen.

(To be concluded).

An Address

DELIVERED AT THE

OBSTETRICAL SOCIETY OF LONDON,

On February 2nd, 1887,

BY J. B. POTTER, M.D., F.R.C.P.,

PRESIDENT OF THE SOCIETY.

GENTLEMEN,—I have again to congratulate the Society on its prosperous and healthy condition. Our numbers at the close of the year were 736. We have lost by death, resignation, and erasure 40 Fellows, but during the year we elected the large number of 72. Including the 25 new members that have been already elected this year, the Society at the present time stands with a total of 761, the highest number that has been reached since its foundation. Our financial position is good. As you have heard from the report of our excellent treasurer, another £100 has been added to our invested funds, making the amount of our capital £1500, and we commence the year with a good balance at our bankers. Our library has been increased by the addition of 156 volumes, bringing up the total to 3690. These are all proofs of our popularity and prosperity; but the success of the Society depends more upon the work done, and we can show continued good results in this. Our midwifery board reports good and still increasing work. The number of women examined reached the large number of 102, of whom 80 were found qualified to receive the Society's diploma; 395 women are now on our register. This gratuitous and honourable work, as was stated last year, causes considerable strain on the Society and its unpaid examiners, and, as the numbers are continually increasing, some scheme will have to be devised to meet the difficulty. It is curious to notice how the value of the Society's diploma has increased when we observe that, whereas in the first eight years only 47 names appear, during last year 102 women presented themselves for examination. The unsettled state of politics still prevents this burning question from coming to the front, as sooner or later it must do; but the Society, if it had no other work to show, may well be proud of having taken in hand this duty, so long neglected by the State. The attendance at our meetings has been good, and the work of the session

Digitized by Google

maintained. The publication of the Transactions in portions has been undertaken for the first time, and, although the circulation has not been large, it has been a boon to those who have availed themselves of it, and an advantage to the Society in bringing its work more rapidly before the notice of the profession.

[Dr. Potter then entered into an enumeration of the more remarkable of the specimens shown and of the chief papers read at the meetings of the Society during the past session.]

I have attempted no more than a slight summary of the work of the Society during the year, and the quality of the papers is an evidence that its scientific standard has been well maintained, and that it has fulfilled its function as established for the promotion of knowledge in all that relates to obstetrics and the diseases of women and children. It may be contended by some that we have not the records to show of great improvements in the practice of our art during the past year—no striking novelties in treatment; but it is the function of the Society to maintain a judicial attitude, and, while assisting progress when the progress is real, to check or arrest this when it tends to danger. In other words, it welcomes improvement, but avoids destruction. One of the highest points that we should aim at is the prevention of disease, and this, though well worked out in the practice of obstetrics, has not received the same attention in the diseases of women. Much has been done at different times to solve the important question, Should any death occur in or after natural labour? And the answer to this question has been each year more favourable, as evidenced by the improved record of our lying-in hospitals. Even in difficult labour mortality has been much reduced, and though the wish expressed by Dr. Tyler Smith in his paper in the first volume of our Transactions for the abolition of craniotomy from obstetric practice in all cases where the fœtus is living and viable has not yet been fully realised, the more frequent induction of premature labour and more timely use of the forceps have conduced much in this direction. In our present state of knowledge we are not yet prepared to accept abdominal section as its alternative in all cases, still holding to the English axiom—the safety of the mother before that of the child. Again, by the use of chloroform and the more frequent application of the forceps we have means of preventing laceration and sloughing of the soft parts, thus rendering far less common the miserable after-effects of a lingering labour. But the prevention of diseases of women has not received the same attention: the effects of cold, damp, climate, occupation, imprudence and want of care at the menstrual periods, the effect of excessive child-bearing, abortions, the prevention of impregnation, and many other causes of disease, deserve and require our careful consideration; and he who can prevent the occurrence of the diseases of women will be a greater benefactor to his race than the operator, however skilful he may be, who treats them.

The whole question of uterine pathology is far too large a one to enter into here, even had we the requisite time at our disposal. To attempt to enter into the various theories that have from time to time given rise to different modes of treatment would be a perplexing and unprofitable task; each seems to reign for a short time only to be cast aside and replaced by some other, and now the tendency seems to grow more and more surgical, until at last to some minds abdominal section and the removal of internal organs seem the panacea for all the evils that woman is heir to. To the indiscriminate use of these procedures we cannot give our adhesion, and especially do we object to the heroic surgical treatment of hysteria—that chameleon disease which still claims so much sympathy and treatment at our hands. Even statistics on these matters, however carefully tabulated, have to be received with caution; the distinction between cases that have recovered or become well and those that can be truly said to have only just escaped death or have lived too frequently with their suffering unrelieved has not always been clearly shown. In estimating these matters much must depend on character. A reputation for truth and logical precision is of more permanent value here than the statement of brilliant results that will not bear the test of investigation. If I have spoken strongly on this matter, it is owing to the fear that some may be apt to forget the sacredness of human life in their zeal for operating, and this must be my excuse.

One task yet remains, and that a sad one. We have always to deplore the loss by death of our members by death. This year fortunately the number has not been so great as on many occasions. Eight have passed away: two of our honorary Fellows—viz., Dr. Simon Thomas of Leyden, and Dr. Courty of Montpellier; and six of our ordinary Fellows. Of the former, Dr. A. E. Simon Thomas of Leyden, whose death was announced so recently as December last, we have not yet been able to find any obituary notice. He was elected an honorary Fellow of the Society in 1866. Many of his works are in our library, one of the most important being his great work on the Oblique Pelvis. For the following notice of M. Courty I am indebted to the memoir published in the *Annales de Gynécologie*, of which journal he was one of the original founders:—

Professor Amédée Courty was born at Montpellier on Nov. 2nd, 1819, his father and grandfather having also followed the profession of medicine. After receiving the usual classical education he threw himself with zeal into the study of medicine, and at the same time devoted himself to the pursuit of science. After taking a licence in Science he became Doctor of Medicine in 1845, the subject of his graduation thesis being "Sur le Développement de l'Œuf dans l'Espèce Humaine." He now gave himself up to the study of physiology, and published several memoirs on this subject, also teaching the subjects of anatomy and surgery until his appointment as a professor in the Faculty of Medicine in Montpellier in 1849, when he wrote a thesis on the use of Anæsthetics in Surgery. In 1854 he wrote a memoir on Cauterisation of the Cervix Uteri with the Actual Cautery during pregnancy. From this time he devoted himself to the special study of the diseases of the genital apparatus in women, and, dissatisfied with the knowledge that he found in the text-books of his time, began to collect materials for the great work on which rests his title to fame, named "Traité Pratique des Maladies de l'Utérus et de ses Annexes," the first edition appearing in 1866, followed by a second and third in 1873 and 1879. This work was translated into English in 1882, with a preface by Dr. Matthews Duncan. Though no doubt largely indebted to the works of German and English authors, still throughout we find the impress of his own mind and the result of his long and patient researches. The great secret of Courty's success in his department of practice was that he became a specialist only after long study and a familiarity with medical and surgical work of many years. On this foundation he grafted his special studies, this being the way in which he understood the term specialty, not following, as is too often the case in the present day, the plan of calling himself a specialist and therefore considering himself one—such a specialist as might be defined as one knowing a very little of one subject and nothing at all of the science and art of medicine. He obtained a large practice in Montpellier, and was largely consulted throughout the south of France. His professorial duties obliged him during his later years to pay frequent visits to Paris, and advantage was taken of his presence by many to avail themselves of his matured knowledge and skill. He took great interest in the French Association for the Advancement of Science, and also in the International Medical Congress. He was a regular attendant and frequent speaker at these meetings. He died on March 2nd at Montpellier. His loss is felt by all the medical world, and especially that part of it devoted to the study of the diseases of women. He was elected an honorary Fellow of this Society in 1875.

Of our ordinary Fellows, John Archer, F.R.C.S., practised in Birmingham, his native town, upwards of fifty years, and was one of the early Fellows of this Society, having been elected in 1859. He was senior surgeon to the Lying-in Hospital, and was an able obstetrician. He was a good type of the general practitioner—honourable, hard-working, and successful. A past president of the Birmingham Medical Institution, he held a most respected professional position in the town. He died on March 8th, at the age of seventy-seven, of angina pectoris.

In speaking of the lamented death of Dr. Alfred Wiltshire, which occurred on the 4th of December, at a comparatively early age, I refer to a loss which is specially felt in our Society; a regular attendant at our meetings, and one who had taken an important part in its management.

[Dr. Potter gave a sketch of the career of the deceased physician, particulars of which were published in our issue of Jan. 1st of the present year.]

Dr. J. Macgrigor Croft, of Abbey-road, practised for many years in St. John's Wood, and died on Jan. 1st. He was elected a Fellow of the Society in 1859.

John M. Burton, F.R.C.S., of Lee, died on Feb. 10th. He

Digitized by Google

was a well-known and respected practitioner in that neighbourhood, where he had passed the whole of his long and industrious life. He became a Fellow of the Society in 1862.

Henry Albert Lovett, M.R.C.S., of Tasmania, died in July, 1885, but his death was only reported to us in 1886. He entered the Society in 1876.

John Gittins, L.R.C.P., of Horselydown, was elected in 1867, and died on July 27th, aged forty-five.

Whilst closing these brief and imperfect records of our departed friends, I cannot but feel how often it has been scanty and insufficient, but this has been due, not to a want of respect and appreciation on our part, but to the absence of knowledge and details at our disposal. It may perhaps be said of them as of many other silent workers—

> "The noblest service comes from nameless hands,
> And the best servant does his work unseen."

It remains to me before leaving this chair, to which I was elected by your kindness two years ago, while apologising to you for my many shortcomings, to thank you for your patient consideration and courtesy to me on all occasions; and especially must I thank our secretaries for the help and assistance they have accorded to me at all times. The work of our secretaries, often laborious and self-denying, is known to few; and I can only say that, as long as the Society is served by such officers as Drs. Herman and Champneys, we need have no fear either for its future prosperity or the promotion of obstetric science. Of my successor whom you have elected unanimously to-night, Dr. John Williams, I need say but little; his name is a household word in the Society. Beyond his other and many qualifications, I know of no one who has its interests more thoroughly at heart, and I can only congratulate the Society on the wisdom of its choice.

CASES OF PERITONITIS.

BY JAMES F. GOODHART, M.D., F.R.C.P.,
PHYSICIAN TO GUY'S HOSPITAL AND THE EVELINA HOSPITAL FOR CHILDREN.

(*Concluded from page 410.*)

Now another point. In some cases suppurative peritonitis is marked by all the severity of symptoms found in acute plastic peritonitis, and in such there will necessarily be the small, thready, wiry pulse, the collapse, and the depressed temperature seen in the more rapid form of the disease. But I am now concerned with the cases of more insidious onset, and in these another negative symptom, in addition to the absence of fever, is quite likely to deceive—viz., the absence or comparative absence of pain. Many years ago I remember examining a man, the other details of whose malady have now escaped me, but as regards whom this has remained firmly fixed in my memory, that he allowed the freest possible manipulation of his abdomen without evincing any pain, and yet within a few hours he was dead, and I found the peritoneum to be full of pus. That was an extreme case, but many times since then I have seen this: that the abdomen has been soft, not markedly distended, and the tenderness, although not absent, has been of the slightest; conditions, in fact, which would of themselves seem to negative rather than to suggest the existence of peritonitis.

Next, a word as regards diarrhœa. Constipation is the symptom of peritonitis, not diarrhœa. So constantly is this the case that, as I have just said, one of the great difficulties of practice is to say whether we are dealing with mechanical obstruction or the obstruction wrought by paralysed peristalsis. I am sure it is quite impossible in some instances to be certain of the nature of the case without having surgically a finger in the pie. Peritonitis is far the more common. But what about diarrhœa? That may well seem to negative peritonitis. It by no means negatives *suppurative* peritonitis. But more than this, I wish to insist that when it exists with any symptoms of peritonitis it is, in my experience, an omen of the gravest, I would almost say fatal, import.

Some have laid stress upon the position of the pain in peritonitis associated with cæcal inflammation. Some have said that it is very liable to be referred to the left groin, others to the umbilicus; I would venture to assert, on the other hand, that the peritoneum is very treacherous in this indication. I remember some years ago making a post-mortem for Sir William Gull and Mr. Bryant upon a lady who had died with an illness of much obscurity; and Sir William Gull said to me before commencing: "I want the liver examined very carefully. I am sure there is some disease in that neighbourhood; there was always so much pain in the right shoulder." This opinion was so far correct that there was a considerable collection of pus between the liver and the diaphragm; but the real disease, of which I believe there had not been a suspicion, was a sloughing cæcal appendix and suppurative peritonitis.

This case leads me to remark upon the very insidious nature of some of these cases. In the two cases I first narrated there were pains in the abdomen, which, had they been more carefully attended to, might possibly have enabled one to avert the disastrous result. But I remember two other cases, which occurred to me some time ago, which well illustrate this point. I was asked by Mr. Alexander to see a policeman, not far from the hospital, because he was having nearly daily repeated rigors of severity associated with a temperature of 103°, and during the attacks his condition seemed to be a very alarming one. He had had a severe attack of epigastric pain and jaundice five months before, but had been well in the meantime. When I saw him he was apparently pretty well, his temperature normal, and all that I could detect was a little tenderness of the abdomen near the gall-bladder. He remained thus without any severe symptoms till the Monday, when he was suddenly seized with intense epigastric pain, collapse, and feeling of impending death, and he died within two and a half hours of his attack. We made a post-mortem examination the next day, and found the cæcal appendix twisted and adherent to the cæcum, dilated into a sac of considerable size near its termination, with smooth abscess-like walls, an ulcer into the peritoneal cavity, and a small concretion escaping. There were extensive adhesions between the liver and the diaphragm, and a large abscess between them and in the right lobe of the liver. Another very similar case, I believe, for there was no post-mortem, I saw with Dr. Boothroyd of New Cross, only a month or two ago, in the person of a healthy-looking man, aged twenty-five. He had had a severe attack of abdominal pain and frequent vomiting four months before, had been very ill at the time, but got quite well. He had been ill nine days when I saw him with remittent attacks of fever, sweating, and rigors. He had a normal temperature, was sweating profusely, his tongue a beefy red, and a rather full abdomen, but nothing capable of localisation. Remembering my former experiences, I could not but fear that there was some deep-seated suppuration about the mid-rib, but in the absence of any indication of its exact seat, and having a dislike to bootless prodding, we decided to wait for further knowledge. I did not see the case again, but Dr. Boothroyd told me that the temperature continued to rise almost daily; the sweating continued, a little more fulness appeared in the epigastrium, and the lower lobe of the left lung became consolidated. Dr. Boothroyd still felt sure that there was an abscess high up in the abdomen between the liver and diaphragm, or in the liver itself, and I have not yet recovered from my disgust at the stupidity of the poor man's friends in refusing any further aid, and in subsequently refusing to let us make an inspection of the body.

One other word about these cases, which always seems to me worth while to insist upon—viz, the frequency with which pleurisy spreads from peritonitis, and peritonitis from pleurisy. I was once in frequent attendance upon a case of empyema with another medical man. It was in an only boy, and anything the matter with him, or rather, in his then condition, any variations in his progress, were the causes of repeated panics. I had left the house one morning, the child doing perfectly well, for the rest of the day, and returning at night found the whole place in a turmoil—another doctor called down from London, whispers of some serious fresh complications, and so on. The child had suddenly been seized with fresh pain in the upper part of the abdomen, and was consequently in great distress for the time; but I believe it was nothing more than the extension of inflammation through the diaphragm, calling for the exhibition of opium. At all events, that treatment was adopted; all the pain subsided, and no further evil happened.

I do not think the freedom of communication between the serous sacs of peritoneum and pleura is sufficiently well reco-

Digitized by Google

gnised. We are all familiar with the jaundice, which is a not uncommon feature of right-sided pneumonia, and we attribute it, perhaps, vaguely to the proximity of the diseased lung to the liver; but it is not so generally known that in a great many cases there is a well-marked inflammation of the peritoneum, in these cases limited to the surface of the liver—a condition, in fact, of direct extension. This extension occurred in three of the cases I have quoted, and I might give several others. Not long ago I saw a boy of fifteen with Mr. Withers Green of Serjeants'-inn, who had been ill five days, and who was then dying of acute peritonitis, but he had, in addition, acute pleurisy spreading up the left side. The point is clearly of much importance both as regards prognosis and treatment. Indeed, as regards diagnosis also it may not be unimportant, as one of the cases I have mentioned shows. Surely, with abdominal pain and vomiting, tenderness in the cæcal region, followed by diarrhœa, and then by an acute form of pleurisy, it is flying in the face of probabilities to suggest anything else than a primary peritonitis followed by the pleurisy. As regards prognosis, too, a daily examination with the stethoscope of the lateral regions of the thorax will help us, sometimes by the discovery of pleuritic inflammation, more correctly to forecast the issue of the case.

I have not much to say dogmatically on the subject of treatment. What I purpose is rather to say a word upon the difficulty that besets us in this matter in these cases in the present day. Take all the cases we have seen, and I suppose this to be the summary — they have all been regularly and properly treated by opium, and perhaps belladonna, local applications, and so on; they have all been properly subjected to a rigorous limitation of food, both as regards quantity and material; some, perhaps, have been fed for a time exclusively on enemata. Nevertheless, some—I will not go into proportions—a good many have got well; but others—others, which at least promised equally well, or better—have rapidly gone to the bad. That is where I stand at present, and I only make the statement personal because I am sure it is the experience of all. We have all seen patients whose condition looked exceedingly grave pull through by skilful medical treatment; we have all of us seen cases that looked well die. See how difficult this experience makes practice in the present day. How can we tell in any given case whether to trust to medical treatment alone, or to commit the fortunes of the patient to the chance of relief by exploring the abdominal cavity. The peritoneum is now dealt with by the surgeon under conditions of antiseptic surgery with the greatest freedom. We hear of ovarian tumours with general peritonitis being removed successfully—nay, more, of patients thus rescued from what seemed the jaws of the grave. We hear of the peritoneum being drained, washed out, sponged out, and so on, with the immediate subsidence of alarming symptoms; and this question must occur to all of us when these cases die without operation, "Could life have been saved by opening the abdomen?" Now I am not writing to advocate any general rule of treatment; my purpose is rather to bring myself as near as may be face to face with the difficulties of anyone called upon to decide this matter, believing that by so doing any one of us will be more master of the situation in the next case of the kind that comes before him, even if we decide nothing at the moment. I have already stated the main difficulty, medically speaking. The deaths make us think, "I wish we had done something"; the recoveries, "I am very glad we waited." Who can help being undecided. But there are other difficulties. I have alluded to the insidious nature and the obscurity of some of these cases. See what this implies: firstly, the inertia resulting from our fear of doing actual harm to the patient, of submitting him to an operation the necessity of which is not quite certain, and which if not necessary is harmful; Secondly, the inertia supplied by the fear that the operation may prove fruitless and the patient die soon after; thirdly, the inertia resulting from a certain regard for our own reputation, for in such a case it is very likely indeed to be said that the operation has killed the patient; and, lastly, the inertia which results from the very natural antipathy in everyone to the resort to painful treatment which is the very breath of the atmosphere of "home." Some may think such things trifles compared with the main—say they the only—question, What is the best thing for the patient?—a stoical maxim of medical ethics which completely demolishes indecision. I venture to think, however, that a paper argument of that kind is overweening, and that it is through such ins-and-outs as have been mentioned that one ultimately has to act. I shall not attempt to decide in any detail what cases should be operated upon, what cases not. I do not think it is possible to decide for more than one case at a time, but I firmly believe that thinking the matter out in this informal way will enable us, sometimes at any rate, to recommend an operation and to save a life. There is no doubt this may be done much less fearlessly than in times gone by; and in any case where the symptoms are severe, and there is any tendency towards localisation of the mischief, this is *par excellence* the one most suitable for operation. Obviously so. But I am further inclined to think that others also, where the inflammation is more generalised, may sometimes be rescued, could we in any given case appraise with sufficient skill the right value of the symptoms, hit off with balanced judgment the proper point—the nick of time—on the inclined plane of deterioration, and courageously make as little as possible, instead of as much as possible, of the inertia remaining.

PHOSPHATIC DIABETES.

BY CHARLES HENRY RALFE, M.D. CANTAB., F.R.C.P.L.,
ASSISTANT-PHYSICIAN, LONDON HOSPITAL.

(*Concluded from p. 413.*)

GROUP 3. *Increased excretion of phosphoric acid alternating or coexisting with saccharine diabetes.*—I am indebted to Mr. Meredith for a unique example, as far as my experience goes, of phosphatic, replacing saccharine, diabetes. The case was that of a young American gentleman, aged twenty-one, and a student of Harvard University. About two years previously to my seeing him he was training for a college boat-race, and one day, whilst practising, he was much exposed to the sun's rays, which fell on the upper part of his back and neck, which were not protected by his rowing jersey. So strong was the action of the sun that he felt very faint, and the next day the skin of his neck was blistered, and for some time afterwards his neck felt stiff. About six months after this it was noticed that he was looking pale and thin, and had lost weight, and he himself complained of weakness and of sciatic pains. Dr. Sabine, his medical attendant, then discovered sugar in his urine, and a sample being sent to the laboratory at Harvard, it was found to contain as much as 5 per cent. of sugar, whilst a decided increase of urea and phosphoric acid was also noted. A strictly regulated diet controlled the amount of sugar, but it always asserted itself again on the slightest breach of discipline or attempt to study, or after more than ordinary exercise. It was then determined that he should come to Europe, and see if anything fresh could be suggested. On his arrival Mr. Meredith kindly gave him my name; the reports of the American physicians were handed me, and the urine of the twenty-four hours was sent to me for analysis. It was extremely acid, normal in amount, but with a specific gravity of 1040; it contained 2½ per cent. of sugar, the patient being on partly restricted diet; there was also considerable excess of urea and phosphoric acid. The patient had lost altogether more than a stone in weight, was much depressed, suffered greatly from headache, pains in the pelvis and thighs, and was also troubled with boils. I ordered the patient to continue his diet, put him on liquor arsenicalis bromidi, and told him to take two Russian vapour baths a week. This treatment was continued three weeks, and the patient was better in every way. There was only a trace of sugar in the urine, the pains had diminished, and there was less headache. The treatment was continued for another month, during which period the patient, instead of residing in London, spent the time chiefly at the seaside. The urine now became free from sugar, except every now and then, when a trace appeared; but, to my astonishment, there was no great fall in the specific gravity, which, with a normal secretion of urine (from forty to fifty ounces daily), ranged from 1030 to 1033; and it was then I found that he was passing daily an enormous quantity of phosphate of lime. I now placed him upon mineral acids with nux vomica, and told him to take a tablespoonful of cod-liver oil once a day in lime-juice, and to spend the summer among the high Alps. A slight relaxa-

Digitized by Google

tion was permitted in his diet, a small quantity of wheat bread and some of the least injurious vegetables, such as tomatoes, French beans, cauliflowers, &c., being allowed. He was away the greater part of three months, and on his return looked much improved, had gained six pounds in weight, lost all his pains and headache, and was able to take long walks without fatigue. The urine still continued at from forty to fifty ounces, but the range of specific gravity was now 1024 to 1027, and the amount of phosphoric acid daily excreted, though far from being within normal limits, was still much reduced; no sugar had been seen for several weeks. He now returned to America, with instructions to follow a moderately restricted diet for at least two years, not to study more than three hours daily, to be careful not to engage in athletic pursuits, and only to take moderate exercise. A year after his return I received a letter to say that he had completely regained his health—that he was completing his course at the university, and that for the summer he intended to camp out west on one of the prairies. His urine, which, according to my advice, is examined once a week, is still normal in quantity, and the specific gravity is nearly so; the sugar only occasionally reappears in minute quantities.

In a second case the phosphaturia coexisted with a mild form of diabetes. This patient first came under notice in 1880; he had suffered some time before from saccharine urine, which, however, had not much affected his general health, when he began almost suddenly to experience constant aching pains in the loins and pelvic region; he also became dispirited and hypochondriacal, and began to lose flesh. The amount of sugar had always been controlled by diet, and at the onset of these symptoms he certainly was not passing more sugar than he had done before. Nor could any correspondence be observed between the amounts of sugar and the amount of phosphoric acid, for the mean of three observations made when no sugar was present in the urine gave a daily excretion of 6·7 grms., and 6·8 grms. (also the mean of three observations) when the sugar was considerable. After treatment the daily average excretion was reduced to 3·8 grms., but the sugar still remained persistent, always returning when the dietetic regulations were at all relaxed. The patient, who is still living, says that the tendency to excessive phosphatic excretion recurs from time to time, and that he can always tell when to send his urine for examination by the recurrence of the boring and aching pains in the loins and pelvis.

In a case for which I am indebted to Mr. Pearce Gould, sugar had been found repeatedly in the urine by the medical attendant, and the patient's diet regulated accordingly. Owing to some mistake, the patient's visit to me was delayed some weeks, during which he was under dietetic restriction. When I saw him, the urine contained no sugar, but had a specific gravity of 1030, was highly acid, and contained a very considerable excess of phosphoric acid. This patient, Mr. Gould tells me, is now quite well.

GROUP 4. *Increased elimination of phosphoric acid, without any special connexion, apparently running an independent course.*—I have notes of five such cases. In all, the elimination of phosphoric acid was considerable; the patients suffered from boring, aching, rheumatic pains in the loins and in the pelvis, together with hypochondriasis and some degree of emaciation. The urines varied; in some the secretion was normal, but in others increased. The urea was always in excess, and with the excessive excretion of phosphoric acid a deposit of calcium oxalate was nearly invariably noted. All complained more or less of constipation alternating with a yeasty-looking diarrhœa, and indigestion and flatulence were always more or less prominent. As these cases correspond in most particulars with those described some years ago by Beneke in his work on the "Pathology of Phosphate and Oxalate of Lime," I have not thought it necessary to quote them separately. None of them resemble those described by Professor Teissier, as simulating saccharine diabetes only without the sugar. As I have said, they seem very much like ordinary cases of so-called oxaluria.

Of the thirteen cases thus briefly recorded all with the exception of two occurred in young male adults. The symptoms common to all, though varying greatly in degree, were—*loss of flesh*, in some cases to the extent of considerable emaciation; *aching rheumatic pains*, chiefly affecting the lower part of the back and pelvic regions; *a dry harsh skin* and a tendency to *boils*; *appetite* generally ravenous, but in some cases a morbid refusal of food. Teissier says that in some cases under his observation *cataract* has developed, just as in saccharine diabetes; this I have never noticed. In the majority of cases there was polyuria, but this in no way approached, either in amount or character, the polyuria of diabetes insipidus. The increase of urinary water rarely ever exceeded four pints and a half; the highest observed, with the exception of the doubtful case of tumour of the brain, was six pints, as compared with the enormous diuresis of diabetes insipidus; whilst instead of the specific gravity falling to an extremely low limit, as in insipid diabetes, it was well maintained, showing that, unlike the insipid form, there was in these cases a very considerable drain of solid matter from the body. In some of the cases, however, the amount of urine passed was normal, but in these the specific gravity was greatly increased, all pointing to the same fact—viz., the *increased elimination of solid matters* by the urine. In all my cases the urea was in excess—in some to a considerable extent; in others it was not so marked. Teissier, however, has published cases in which no increase of urea was observed, and he contends that it is not at all necessary that there should be any when there is an increased elimination of phosphoric acid. On this point an observation of Sir William Roberts throws some light. Speaking of the cases originally described by Prout under the term "azoturia"—cases exhibiting a dense urine and a train of nervous symptoms,—he says that these turned out, on more exact investigation, to want the special feature indicated by Prout as the essential one—namely, an absolute increase in the daily discharge of urea. It does not appear that in these cases Sir William Roberts determined the amount of phosphates present in the urine; had he done so, he most probably would have found them in considerable excess. Indeed, it is difficult to account for the increased density of the urine otherwise; for if there was no excess of urea, and there was no sugar present, what else could increase the density of the urine but the inorganic constituents? Now an excess of chlorides does not increase the density of urine, because, unless water is withheld, they always increase the flow of aqueous excretion, so, if anything, the specific gravity falls. Whilst the sulphates when in excess in the urine are always accompanied by excess of urea, which Sir William Roberts tells us in these cases was not observed. There remains therefore only the phosphates as likely to cause the increased density of urine; and as Professor Teissier has shown, and as also the observations of Zuelzer, Edlessen, and others have shown, the excretion of phosphoric acid may be very greatly increased without any corresponding increase in the amount of urea. The great feature, therefore, of these cases is *the increased elimination of phosphoric acid, with or without a corresponding increase of the other constituents of the urine:* a feature which distinguishes it from *insipid diabetes*, with which it has been improperly confounded, and in which there is only an increase of water and no other morbid change; and from *azoturia*, in which urea is decidedly increased.

With regard to the pathology of the condition, many views have been brought forward, which are too numerous for discussion here. I will only therefore mention those that occur to me as being most probable. In the first place I would reduce the four groups to two—placing Groups 1 and 2 together, and likewise combining Groups 3 and 4. I do not believe that phthisis is ever necessarily attended or preceded by an exaggerated excretion of phosphoric acid. I have examined the urine of a good many tubercular and phthisical patients in all stages, and failed to establish anything of the sort. It is true that Marcet has found a great diminution of phosphoric acid in the ash of diseased lung as compared with healthy lung, but the removal of the phosphoric acid would be so gradual as scarcely to affect the urinary secretion. I believe, therefore, that the cases of increased excretion of phosphoric acid associated with lung disease are accidental. Naturally one would expect abnormal tissue metabolism in weak and delicate subjects, and certainly phthisical tendencies would be likely to be developed in persons suffering from a long-continued drain of such an important vital constituent as phosphorus.

Then, again, with regard to the cases in which nervous symptoms are prominent, are these due to disintegration of nervous tissue? is there increased oxidation going on? and are the phosphates an expression of the destruction of tissue? I think not, and I think the fact that the other urinary constituents are not always increased *pari passu* strongly against this view; whilst the fact established by recent German

Digitized by Google

observers, that increased elimination of phosphoric acid occurs chiefly in depressed conditions of the nervous system, and that there is evidence of lowered vitality generally, points, to my mind, rather to defective than to increased metabolism, that the tissues are unable to utilise the phosphorus brought to them for nutrition, and that consequently a greater amount has to pass through the system daily. I am therefore inclined to classify the first two groups as *cases of excessive elimination of phosphoric acid dependent upon defective nutrition.*

With regard to the last two groups, the one relating to the connexion between sugar and phosphoric acid in diabetes mellitus is the more interesting. Many explanations have also here been suggested. One, that phosphoric acid replaces the sugar in consequence of some occult change in the nervous system, may be dismissed as visionary and vague. The others that occur to me as being most likely are (*a*) that instead of the sugar passing into the urine, it becomes partially oxidised in the system into a series of acids—oxybutyric, crotonic, glycollic, lactic, &c.,—which, circulating through the tissues, dissolves out the phosphates, especially the earthy salts. This explanation receives support from recently ascertained facts respecting the nature of the "acid intoxication" that so frequently marks the course of diabetes. The other explanation is that in diabetes mellitus, as is now a well-recognised fact, there is a considerable elimination of phosphorus in an unoxidised form, as lecithin, or glycerine phosphoric acid. Now, should improved oxidation take place in the body, this unoxidised phosphorus would probably undergo oxidation and appear as phosphoric acid. This view is supported by the fact that in the two cases in which sugar had been observed, but had disappeared and been replaced by an excessive excretion of phosphoric acid, the tendency was towards recovery. At first, with defective oxidation there was sugar and probably unoxidised phosphorus; with improved oxidation the sugar disappeared, and the lecithin or glycerine phosphoric acid was oxidised into phosphoric acid; and a further improvement led to the disappearance of the excessive excretion of phosphoric acid and ultimate restoration of health. No doubt both conditions—namely, the imperfect oxidation of sugar into intermediate acids and the oxidation of unoxidised phosphorus into phosphoric acid—are at work in these cases. With regard to Group 4, which ran a distinct course without association with any special form of disease, as I have already said they seem to correspond, as far as I have been able to judge, with those cases of oxaluria attended with increased excretion of phosphoric acid described by Beneke, who considered them to be due to the excessive formation of lactic acid in the intestines and its absorption into the body and dissolution of the phosphates out of the tissues. These cases, then, probably depend on a similar condition, such as that which causes the appearance in excess of phosphates in saccharine diabetes. I think, therefore, we may classify these two groups as *cases of excessive elimination of phosphoric acid dependent on abnormal formation of acid within the body.*

With regard to the prognosis in these cases, those arising from defective nutrition are the most unsatisfactory. With rest—or, better still, the employment of massage—they regain weight, and the excessive elimination of phosphoric acid is somewhat diminished, never completely; then when allowed to get about they fall back again, till, owing to the general exhaustion, they become victims to some acute disease, or else drift on into phthisis, or, as Teissier says, sometimes into saccharine diabetes.

With respect to the second division, the prognosis is more favourable. Of the three cases of saccharine diabetes associated with considerable excretion of phosphoric acid, two got quite well; the first step being the replacement of the sugar by phosphoric acid in excess. The second case has remained a mild case of diabetes mellitus for over seven years.

Concerning the cases resembling oxaluria with increased phosphoric acid excretion, they usually get much better under appropriate treatment, but are troublesome from their frequent relapses.

Lastly, in respect to the term "phosphatic diabetes," as will have been gathered from the preceding remarks, excessive elimination of phosphoric acid is symptomatic rather than a disease *per se*. It would be wrong, therefore, to use such a distinctive appellation without strictly limiting the conditions of its use. And this would be to employ it as a distinguishing term from "phosphaturia." This latter admirably describes that condition in which phosphates are precipitated from alkaline urine, whether fixed or volatile; but as it would be awkward to speak of phosphaturia due to deposition, and of phosphaturia due to excessive elimination, I would propose to use the term "phosphatic diabetes" to distinguish the latter, and retain phosphaturia to designate the former, condition.

Queen Anne-street, W.

CASE OF

TREPHINING OVER THE LEFT BRACHIAL CENTRE FOR PARALYSIS OF THE RIGHT ARM DUE TO A BLOW A WEEK PREVIOUSLY; CURE OF PATIENT.

BY A. W. MAYO ROBSON, F.R.C.S.,
HONORARY SURGEON TO THE LEEDS GENERAL INFIRMARY, AND LECTURER ON OPERATIVE SURGERY AT THE YORKSHIRE COLLEGE.

THE following case, the notes of which have been furnished by my house-surgeon, Mr. Ashton Street, presents so many points of interest that I venture to think a somewhat detailed description may interest the readers of THE LANCET, especially at a time when cerebral localisation, as applied to brain surgery, is engaging the attention of the profession.

J. S——, aged thirty-eight, was admitted into the General Infirmary, Leeds, on August 9th, under the care of Mr. Mayo Robson. He gave the following account. Whilst walking along the street six days previously he was struck from behind over the head by a buckhorn-handled stick. He does not remember the blow, and was totally unconscious for ten hours. Just before recovering consciousness there was some vomiting. He noticed as soon as he regained his senses that he had lost the use of his right hand. He was dizzy and confused for some days, and had impairment of memory, as he remembered some events in the police-court, but not all. He was so far bright and intelligent, however, as to give evidence in court the day after the accident. He was apparently so little injured that a surgeon who saw him thought his arm was powerless from simple bruising due to the fall, and his head so little damaged as not to require dressing. He noticed that his right fingers and hand began to twitch twenty-four hours before admission.

On admission there was a lacerated wound about $\frac{1}{3}$ in. long, too small even to admit the tip of the little finger, situated over the left side of the skull, $5\frac{3}{4}$ in. from the root of the nose, 5 in. from the left external angular process of the frontal bone, $4\frac{3}{4}$ in. from the root of the zygoma, $6\frac{1}{2}$ in. from the external occipital protuberance, and $1\frac{1}{2}$ in. to the left of the middle line. On digital examination through the integuments very little could be made out, as there was some inflammatory swelling; but on probing the wound bare bone could be plainly felt, and at the posterior part the probe could be felt to drop suddenly for about $\frac{1}{4}$ in. The whole of the right forearm and hand were markedly paralysed, the extensors and supinators being entirely powerless, whilst with the flexors he could barely make his grasp felt. The muscles of the upper arm were only half as strong as those of the opposite side, but the shoulder muscles were equally powerful. Sensation was much impaired, considerable pressure being needed to make him feel; but when he did he recognised the kind of touch and noticed the temperature. There were constant rhythmic twitchings of the fingers, and occasionally of the hand and arm, those of the fingers being about 40 per minute. The hands were of the same temperature, but he had a peculiar numbness in the right. He was able to walk, the right leg seeming to be as powerful as the left; but the cremasteric and knee reflexes were both exaggerated on the right side. He was able to whistle, but not nearly so loud as before the accident, and could only screw his eyes up with difficulty. His pupils were of medium size and reacted quickly to light. There was well-marked œdema of the left optic disc; his sight, however, was good. Hearing was slightly deficient. He complained of pain at the seat of the wound and all over the frontal region, but more on the left side. He was perfectly conscious and answered questions with rapidity. His

Digitized by Google

breathing was easy and tranquil; his pulse 85, full and soft; his temperature in the axilla 98·4°. He could swallow well, and passed urine normally.

Mr. Mayo Robson at once decided to operate. The patient having been put under ether, the head was shaved and cleaned, first with turpentine and afterwards with perchloride of mercury solution. Under the spray, and with full antiseptic precautions, a crucial incision was made, the arms being 1½ in. long. The flaps so formed were reflected, exposing the wound in the bone, which was found to be a trifle over ⅜ in. in diameter. The whole piece of bone was depressed, the posterior part being more so than the anterior. The margins of the surrounding bone were remarkably clean cut and circular, almost as if a piece had been punched out. The periosteum from the neighbouring bone was not stripped. A trephine ⅝ in. in diameter was applied, but as the centre pin could not be used rather more bone was taken from the posterior edge than in front. The outer table and diploë were then raised in one piece by the elevator, but the inner table was found to be splintered in all directions, one piece of the size of a finger-nail depressing the membranes very considerably, just over the ascending frontal convolution. These fragments were carefully picked out, but without using much force, as the dura mater was stripped from them. The dura mater, which bulged slightly into the wound after the bone had been raised, was markedly pulsating; it was not perforated, and the surface seemed perfectly healthy. The wound was syringed out with perchloride lotion (1 in 500), and the bleeding vessels in the flaps, which had been temporarily stopped by clips, were ligatured. The flaps were then stitched with catgut, and a small drainage-tube put in the centre, so that the bottom of it was just free of the dura mater. The wound was again syringed and dressed with a layer of wet carbolic gauze, iodoform, and salicylic silk. The patient took ether very well, but his pupils dilated and remained so during the operation. After the elevation, and whilst the patient was still under ether, it was noticed that the twitchings had ceased, but whether this was due to the anæsthetic or to the operation is not known, as, unfortunately, the condition of the hand was not noticed before the elevation. The whole operation only lasted twenty-five minutes. He soon recovered from the anæsthetic, and for the first hour had great pain in his head, but the twitchings in the hand had ceased; they returned, however, in the second hour with greater severity. At 6 P.M.—i.e., four hours after the operation—he was much easier. Temperature 98·6°; pulse 80. At 12 P.M. the patient slept, but was restless; he had no pain except slight frontal headache. The hand was much stiller. Pulse 72. The twitchings did not stop during sleep.

Aug. 10th.—Patient felt much better and had no pain; pulse 72.—11th: Slept well in the night, and during sleep the movements of the hand stopped. Wound was dressed for the first time, the spray being used. The tube was removed, as the wound looked well and there was no pus. Movements of fingers were much less frequent.—12th: Patient was so well that he wanted to get up. Temperature and pulse normal. His diet having been confined to fluids since admission, he felt hungry, and asked for and was ordered solid food. Power in the hand had very slightly returned. Twitchings were rather less frequent. Had slight soreness in the concatinate glands. Temperature normal.—15th: Patient dressed, as the glands were rather swollen and painful. There was a little œdema of the scalp, but no suppuration. The centre of the wound where the blow was given gaped a little, as the tissues had been bruised and lacerated. Pulse 70.—17th: Swelling of glands was subsiding. Dressed under the spray, and the wound found healed, except the centre of the cross, which was still open. Twitchings had completely gone, and since the 15th he had only had one or two, when he attempted to raise the arm. Patient could hold his hand straight up without the fingers falling. Slight increase of power when the hand was held horizontally.—19th: Grasp of right hand could be plainly felt in any position, equal to the grasp of thumb and forefinger of the left hand. The œdema of the optic disc had disappeared, the outline being clear and normal.—21st: Grasp of dynomometer with right hand 35 lb., with left 95 lb.—25th: Grasp of right hand 50 lb., left 95 lb.—28th: Patient got up, but felt a little dizzy.—Sept. 3rd: Wound quite healed. Grasp of right hand 70 lb.—11th: Patient discharged cured. Both hands and arms equally strong. No headache or dizziness. Sensation perfect. The temperature throughout had been normal.

Remarks.—The man had evidently only been seen casually by a surgeon on account of the arm, which the patient thought had been bruised by the fall, the head injury appearing trivial; but the case illustrates well the great importance of a very careful examination in all, even trifling, head injuries, as out of this misapprehension arose a medico-legal difficulty, the assailant having been sent for a week to prison for ordinary assault, when it might have been a case of manslaughter. Further points of interest in the case are—(*a*) The recovery of consciousness and intelligence within a few hours of the accident, although the local paralysis continued; concussion apparently accounting for the former and bruising and pressure for the latter. (*b*) The exact correspondence as proved by measurement of the brachial centre and the wound. (*c*) The threatened extension of paralysis to the facial, which adjoins the brachial centre. (*d*) The congestion of the optic disc on the injured side, which congestion disappeared within a few days of the operation. (*e*) The exaggerated cremasteric and knee reflexes on the right side. (*f*) The localised rhythmic epileptiform movements of the paralysed hand and arm, which began on the fifth day after the accident, were forty to the minute at the time of operation, ceased for an hour afterwards, then returned as frequently as ever, to gradually lessen in violence and number until they disappeared on the sixth day after operation. (*g*) In the success of the measures taken to render the wound aseptic, although it was thoroughly septic at the time of admission, and had been exposed for six days previously. (*h*) Lastly, in the complete and perfect recovery of the patient.

Leeds.

PYREXIA AND HYPERPYREXIA.

BY T. J. MACLAGAN, M.D., M.R.C.P.,
PHYSICIAN IN ORDINARY TO THEIR ROYAL HIGHNESSES PRINCE AND PRINCESS CHRISTIAN OF SCHLESWIG HOLSTEIN.

(*Continued from page 416.*)

IT is evident that the view that the nervous symptoms of hyperpyrexia are caused by the high temperature lacks the clinical support which would commend it to our reason. Experimental evidence seems to afford to it more support. The chief evidence of this kind is that adduced by Wood.[1] He placed rabbits, cats, and dogs in a box, and raised the temperature of this 120° to 130°, and found that in animals so exposed the temperature rapidly rose, and that by the time it reached eight or ten degrees above the normal the animals died. The experiments were evidently performed with great care, and the results very accurately noted. From these Dr. Wood draws the conclusion that it may be regarded as proven that "external heat applied to the body of normal animals, including man, so as to elevate the internal temperature, produces derangements of the functions of innervation, of respiration, of circulation, &c., precisely similar to those seen in natural fever, the intensity of the disturbance being directly proportionate to the rise in temperature." He further adds, no doubt in explanation of his including man in this generalisation, that "the brain of a man is much more highly organised, and no doubt correspondingly more sensitive, than that of a cat; and if a temperature of 113° F. be fatal to the brain of a cat, whose normal temperature is 102·5°, it seems very certain that the temperature of some cases of insolation (113°) is sufficient in itself to cause death in man, whose normal temperature is 99°. Much as one admires the patience and skill with which Dr. Wood made his observations, one cannot fail to see that they do not warrant these inferences, and that Dr. Wood has failed to grasp the correct interpretation and bearing of his own facts.

In the first place, there are no grounds for "including man" in the general inference which he draws. No observations were made on man, and in this matter the results of experiments made on cats and dogs cannot be accepted as applicable to him. Man naturally eliminates through his skin an enormous amount of heat, and possesses a power of accommodating himself to high temperatures, which is not possessed by the animals experimented on by Dr. Wood.

[1] Fever: a Study in Morbid and Normal Physiology. By B. C. Wood M.A., M.D. Philadelphia, 1880.

Digitized by Google

The temperature which he found proved fatal to cats and dogs is one to which man may be and constantly is exposed, without serious results. Every time we take a Turkish bath we are exposed for a length of time to a much higher temperature than that to which Dr. Wood's animals were exposed.

In the second place, it is not an accurate statement of the physiological position to say that because a man's brain is more highly organised than a cat's it is correspondingly more sensitive to heat; and that because the normal temperature of man is 98·5°, a temperature of 113° must be a more serious thing to him than it is to a cat whose normal temperature is 102·5°. What Dr. Wood really found was that when the bodily temperature of rabbits, cats, and dogs rose 8° or 10° above the normal the animals died. But a rise of 8° or 10° above the normal produces *per se* no serious symptoms in man, as is evidenced by the frequency with which such a temperature occurs in relapsing fever without the occurence of any other symptom to distinguish the cases in which it occurs from those in which the temperature is several degrees lower. That is the proper way to put Dr. Wood's facts. The reason why the temperature which he found to be fatal to cats and dogs does not produce serious results in man is that he can naturally bear a much higher temperature than they, and that the surface of his body possesses a heat-eliminating function which is not possessed by that of cats and dogs.

Then, again, I do not think that Dr. Wood has correctly interpreted the mode in which death was produced in his animals. He says that the derangements produced were "precisely similar to those seen in natural fever, the intensity of the disturbance being directly proportionate to the rise in temperature." Of course, this disturbance was most pronounced in the animals which died. But when we come to inquire into their mode of death, we find it stated that in these fatal cases the heart continued to beat for some time after respiration had ceased. Now, there is no form of fever in which death is ever brought about in that way. In fever death results either from asthenia or coma—cessation of cardiac or cessation of cerebral function; but in Dr. Wood's animals it was brought about by arrest of pulmonary function. His animals died neither of pyrexia nor of hyperpyrexia, but from cessation of pulmonary function; and it is not difficult to say why this should have been their mode of death. Man eliminates heat by the skin; the animals experimented on by Dr. Wood eliminate it by the lungs. Breathing as they did in the hot box an atmosphere with a temperature many degrees above that of their blood, it was impossible for them to throw off heat; in such an atmosphere they could not eliminate heat any more than they could eliminate carbonic acid in an atmosphere charged with that gas; heat therefore accumulated in the system. The result of the accumulation in the system of any excretory compound is first stimulation, and ultimately arrest, of the functional activity of the organ by which it is normally eliminated. Accumulation of heat in the blood of Dr. Wood's animals thus led to arrest of pulmonary function, much in the same way that accumulation of carbonic acid in their blood would have done. It was not the heat they took in, but the heat which they failed to give off, that killed them. That was how and why his animals died. But that is a result which could not be produced in man by a like agency, simply because he eliminates heat through his skin. He might die from too great heat, but death would not be brought about by arrest of pulmonary function.

Moreover, there is another point in connexion with Dr. Wood's investigation which, though a side issue, is not altogether to be lost sight of. In his animals heat was applied artificially; by this they were heated up, and the sole question for consideration is the action of this heat on their economy; but in fever and hyperpyrexia there is no artificial heat, and the question at issue is not only the action of the high temperature, but also its mode of production—not only what does the heat do, but how does it come to be there. On this, the main question which has to be considered in dealing with this subject of the hyperpyretic state as it occurs in man, the experiments referred to throw no light. Reasons will hereafter be given for the belief that the high temperature is a result rather than a cause of disturbance of the nervous centres. Meantime, I wish only to point out that, so far as concerns the action of high temperatures on his organism, **man is not** in the same position as the animals experimented on by Dr. Wood—that he possesses a power of accommodating himself to extremes of temperature which is not possessed by them, and that, for the reasons given, Dr. Wood's experiments cannot be regarded as supporting the view that in the hyperpyrexia of man the high temperature is the cause of the nervous symptoms. It is incumbent upon us to explain the occurrence of the high temperature, as well as the nervous symptoms; and no view of the mode of production of the condition to which we apply the term hyperpyrexia can be regarded as satisfactory which does not explain one of its most prominent and striking features—that from which it takes its name. But on the view that the high temperature is primary, how are we to do so? It is evident that neither the clinical nor the experimental evidence favours the view that the high temperature is the cause of the nervous symptoms. The alternative view, that the high temperature is secondary to disturbance of the nervous centres, has much more to commend it. The constancy with which, under the most diverse external conditions—in the Arctic cold as in the heat of the tropics,—the temperature of the human body remains at 98·4°, has led physiologists to look beyond the crude physical conditions of tissue change and surface transpiration, and to regard a special centre controlling and regulating the formation and elimination of heat as essential to the explanation of the phenomena which have to be considered. Without some such regulating centre it is difficult to see how the temperature equilibrium could fail to be frequently disturbed by agencies which, as it is, have no effect upon it.

The tendency of modern physiology and modern research is more and more towards the recognition of the doctrine of localisation of cerebral function, according to which circumscribed and limited portions of the nervous centres preside over, control, and regulate particular actions and functions. We recognise the existence of centres for the special senses of sight, hearing, taste, &c., as well as for speech, mastication, deglutition, &c., and the position of these in the nervous centres can be defined with more or less exactness. We recognise, too, and define the position of a respiratory centre, a cardiac centre, and a vaso-motor centre. But we go even further than this, for the experimental investigations of Fritsch and Hitzig, of Ferrier, Yeo, Munk, and others, have enabled these observers to map out on the surface of the brain a series of circumscribed areas, stimulation of which by means of electricity causes contraction of certain muscles of the opposite side of the body. Thus they have been enabled to demonstrate that particular groups of muscles are presided over by a special portion of brain. The muscles of the forearm have their special area; the muscles of the face have another; a third presides over the muscles of the tail; and so on, each particular group of muscles being apparently presided over by a special central motor area. With the localisation of cerebral function thus demonstrated in so many cases, and with even the position of various controlling centres thus more or less accurately defined, we have good *a priori* grounds for regarding the existence of a thermic centre as at least not impossible. But there exist other than *a priori* reasons. There is not a little evidence, both physiological and pathological, that such a centre does exist.

In 1837 Sir Benjamin Brodie drew attention to the fact that injury to the upper part of the cord was, under certain circumstances, followed by a great rise in the temperature of the body. Since then the accuracy of Brodie's statement has been amply confirmed. The subject has recently been experimentally investigated by Dr. Wood, and much valuable information has been got from his researches. He made sections high up in the cords of a large number of dogs, the general result of which was to show "that after section of the cord there are two distinct antagonistic forces at work, the one depressing, the other increasing, the production of heat." The nature of these forces was determined by carefully conducted experiments. It had already been shown by the researches of Dittmar, Owsjannikow, and Heidenhaim, conducted independently of each other, that the chief vaso-motor centre has its seat in the medulla oblongata. Owsjannikow defined its seat as being in a region "whose upper boundary is one or two millimetres below the corpora quadrigemina, and whose lower boundary is four or five millimetres above the point of the calamus scriptorius." Wood made a number of experiments with the object of satisfying himself on this point, and came to the conclusion that Owsjannikow's statement was accurate. "The evidence," he says, "seems to me conclusive that the chief governing vaso-motor centre is placed

Digitized by Google

in the lower part of the floor of the fourth ventricle near the point of the calamus"—almost exactly the seat assigned to it by Owsjannikow. Stimulation of this centre causes contraction of all the arteries, and consequent great increase of arterial blood-pressure. Paralysis of this centre causes dilatation of the arteries, and fall of blood-pressure. Such changes in the circulation could not fail to have a modifying influence on the temperature of the body; for it is obvious that contraction of the arteries would lead to diminished flow of blood to the surface of the body and consequent diminution in loss of heat, while their dilatation would have the reverse effect. In investigating the effects of section of the cord on the temperature of the body it was therefore essential to determine how far the results obtained were or were not due to injury of the vaso-motor centre and consequent disturbance of the circulation.

Having satisfied himself of the exact situation of this centre, Wood proceeded to make sections above and below it, and to contrast the results. Section of the cord below the vaso-motor centre paralysed the vaso-motor nerves. The immediate result of this is dilatation of the bloodvessels. This flushing of the superficial vessels necessarily leads to great loss of heat. The blood being spread out, as it were, over the surface of the body, is more freely exposed to the cooling influence of the atmosphere, and more readily parts with its heat. The results of his carefully conducted experiments satisfied Wood that "injuries of the medulla below the calamus cause a fall of the animal temperature and of arterial pressure, and confirm the belief that the fall of temperature is due to vaso-motor paralysis."

The next point was to determine the effects of wounds of the medulla made high enough up to avoid injury of the vaso-motor centre; with this object a number of experiments were made. The matter is thus summed up: "The results of our whole study as to the effects of separation of the medulla from the pons upon thermogenesis may be formulated as follows: Section of the medulla at its junction with the pons is followed by increased heat-dissipation and increased heat-production, the increased dissipation usually not keeping pace with the increased production, so that the bodily temperature rises." The increased dissipation is, of course, merely a result of the greater heat of the body—a result which necessarily follows increased production when the vaso-motor system is intact. "Increased heat-production being the cause of the increased heat-dissipation, the problem presents itself—What is the cause of the increased heat-production?"

It was suggested by Heidenhaim that the rise of temperature might result from irritation of the vaso-motor centres; but, as Wood remarks, "it is a general guiding principle in making deductions that section of a nerve induces abolition of function, and that the symptoms which follow such section are paralytic unless clearly proved to be of other nature"; and the arguments which he adduces seem quite to warrant the conclusion at which he arrives, "that the rise of bodily temperature and of heat-production following separation of the pons from the medulla is paralytic and due to the removal of some active force." The general result of all the observations is thus summed up by Wood: "The theory that teaches the existence of a nerve centre in the pons or in the brain above it, which by a direct action inhibits the production of animal heat, seems to be most in accord with all the evidence bearing upon it, and I am disposed to adopt it as at least probable."

Reference has already been made to Sir Benjamin Brodie's observation as to the effect of injuries of the upper part of the cord on the temperature of the body. Since he wrote other surgeons have made similar observations, and sudden and great rise of body heat has come to be regarded as not an uncommon symptom in injuries affecting the cervical column. Weber,[2] for instance, has recorded cases in which the temperature rose to 110° and 111° before death. Churchill[3] records one in which it rose to 110°. Other cases, too, have been recorded in which injuries involving this region have been followed by the opposite condition—a great fall of temperature. Mr. Hutchinson[4] has related a case of crushing of the cord at the fifth cervical vertebra, in which within twenty-four hours after the injury the temperature in the urethra was 93°, and in the rectum, 95·8°.

Much difficulty has been experienced in offering an explanation of these facts, the difficulty arising, as Mr. Jacobson[5] observes, from "the uncertainty as to the existence of any centre which presides over the production of heat, and the connexion between the production of excessive temperature and vaso-motor paralysis." Wood's experiments throw considerable light on this subject, and tend to remove much of the difficulty referred to by Mr. Jacobson. If the injury paralyses only the vaso-motor nerves, there will be distension of the vessels on the surface of the body and rapid loss of heat, such as Wood found follow section of the cord below the medulla. If the thermal inhibitory nerves are paralysed, there will be a rapid rise of temperature. The injury which results from crushing the cord is much rougher and coarser than that made by cutting it, and the same nicety of result is not to be expected. Crushing of the cord at a given point does not mean exactly the same damage in each case; for the injury is a rough one, and one portion of the cord may be more seriously damaged than another—the right side more than the left, the anterior more than the posterior surface, and *vice versâ*. It is not the thermal or vaso-motor centre that is injured in these accidents, but the nerves proceeding from these; and it is an accident, whether in a given case the thermal or vaso-motor nerves suffer most. According as one or the other is more affected the temperature rises or falls.

Injuries of the cervical cord are not the only lesions of the nervous centres in which alterations of temperature are noted. One of the many important results which have accrued from the use of the clinical thermometer is the discovery of the fact that hæmorrhagic and other non-inflammatory lesions of the brain are frequently followed by a rise in the temperature of the body. The subject is one which has come into existence only since the thermometer came into general use; its literature is, therefore, not extensive; but a sufficient number of observations have been made to demonstrate that lesions of the brain frequently cause a rise of temperature such as does not result from similar lesions in any other organ.

Charcot[6] divides the apoplectic state resulting from hæmorrhage or from cerebral softening into three periods, according to the modifications of temperature: in the first, comprising the first few hours immediately following the attack, the temperature falls below the normal; in the second, which lasts a variable number of days, it varies from 99° to 100°; in the third, which terminates necessarily and speedily in death, it runs up to 102°, 104°, and even 106°. Bourneville[7] divides it into four: (1) the initial lowering of the temperature, (2) the stationary period, (3) the ascending period, and (4) the terminal temperature. The first three are the same as Charcot's. The fourth, which is really the maximum point of the third, is added to indicate that the ascending period does not always stop short at the point noted by Charcot; but that *at the instant of death or some minutes after*, there takes place in some cases a very remarkable rise. M. Bourneville gives a table of seventeen cases, eight of which were observed by himself, in which the average temperature a short time before or after death was nearly 107°, while in eight of the seventeen it exceeded 108°. The initial lowering of the temperature is no doubt the result of shock. The second or stationary period is sometimes altogether absent, and after the initial lowering has passed off there may be noted only the rapid rise of temperature of the third and fourth. This stationary period is met with chiefly in cases in which the clot is comparatively small, and in which the ventricles are not injured. Should recovery take place, the stationary period is succeeded by a return of the temperature to the normal standard. Should the case tend to a fatal result, the second period runs into the third, and the temperature rapidly rises. A rising temperature, therefore, indicates a speedily fatal termination.

Since Bourneville's cases were published similar ones have been recorded by other observers; the accuracy of his statements has been amply confirmed, and a rise of temperature has come to be regarded as a common result of cerebral hæmorrhage. But hæmorrhage is not the only form of cerebral lesion in which such alteration of the body heat is noted. The same change has been found to take place in tumours and various other non-inflammatory lesions of the nervous centres. *(To be continued.)*

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF CHOLERAIC DIARRHŒA WITH COLLAPSE.

BY G. CHILDS-MACDONALD, M.D.

ON Sunday, Feb. 20th, I was called to W. D——, a grocer's assistant, who was engaged on Saturday the 19th in packing up goods in hay taken from a case of wine recently received from Italy. On returning home that evening he felt unwell, and early on Sunday morning was suddenly seized with cramps, purging, and vomiting, the evacuations passing from him like water. At the commencement he was able to walk to the lavatory, but he rapidly became so weak that this was impossible. The vomited matters were composed of almost pure water. When seen by me at 11 A.M. on Sunday he had had sixteen evacuations, all of which unfortunately had been carefully emptied before my arrival. The sheets, however, at the upper part were soaked with apparently water, but which afterwards proved to be vomit. The man was lying on his left side, and in the semi-flexed position; the eyes were deeply sunken; the nose, chin, forearms, hands, and legs and feet cold and cyanosed; the tongue cold and dry. There was complete absence of the pulse at the wrist, the heart was beating feebly and almost inaudibly. The respiration was sighing. He would at times throw the arms over the head with an almost spasmodic catch in the breath; in fact he showed all the symptoms of oxygen hunger. Mentalisation was slow; there was also slight dimness of sight and deafness. The pupils were equal and slightly dilated, the eyelids closed. Every minute or so he would rouse slightly with a cry of pain caused by cramp in the abdominal muscles and calves, to relapse again into a semi-conscious condition. No urine had been passed since the previous evening, and the bladder was quite empty. He was given immediately thirty minims of ether hypodermically over the right pectoral region, ordered hot-water bottles to the sides and extremities, sinapisms to the calves and over the cardiac region, hot coffee with brandy, and to be rubbed with the latter spirit; also a mixture composed of acidi sulph. aromat., sp. æth. co., tinct. opii, ol. cajaputi, and ol. menth. pip., aq.; an ounce to be taken every three hours. At 12.30 there was a little improvement. The pulse was just perceptible at the wrist. No further motion or urine. Cramps the same. At 7.30 he had made a sudden attempt to get out of bed, and in so doing he had fallen and injured his forehead. The extremities are warmer. Pulse 80 (very feeble); temperature subnormal. Cramps less. Says he feels better, but complains of great thirst. No stool or urine.—Feb. 21st: Passed a very restless night. Cramps at intervals. Vomited several times. No urine or motion. Pulse 84 (weak); temperature 98°. Skin dry, but tongue moist; bladder empty. Ordered sinapisms to epigastric region, milk and lime water, and a little ice to suck if nausea continues. Linseed poultices to be applied over loins and diuretic mixture to be taken. Evening: Pulse fuller (84); temperature 97·4°. Vomited only once. No cramp, motion, or urine. Ordered eggs and milk, and meat juice.—22nd: Had a better night. Two stools, but small in amount, mainly composed of slimy material; no blood in them; no urine. Complains of flatus and great prostration. Has vomited once a little bilious fluid. Keeps eyes still closed. No cramp. Ordered a little rice pudding.—23rd: Has had a good night and passed fifty ounces of urine. Has had a small loose motion. Vomited bilious matter and mucus twice. No return of cramp. Is much brighter and cheerful, but complains of headache. Temperature 97·5°; pulse 60, much improved in volume. Ordered one ounce of bismuth, digitalis, and ether mixture, three times a day. Since the above note he has steadily improved up to to-day (the 28th), when he can sit up and read the paper. His appetite has much improved, and he had a little fish for dinner. Although, up he is unable to leave the bedroom, and shows great muscular weakness and emaciation.

There are several points of interest in the case, especially as there is so much of the so-called winter diarrhœa about. It would be interesting to know how much the Italian hay had to do with it. The long time the kidneys remained inactive, nearly three days, without uræmic symptoms, is specially noteworthy; also the rapid and evidently complete evacuation, followed by such extreme collapse. I have never seen anyone so near death and recover as this man; probably the ether saved his life. I have called this choleraic diarrhœa with collapse. Some of my readers might give it another name. It is unfortunate that the stools were not seen.

Duchess-street, Cavendish-square.

A CASE OF LACERATED WOUND TREATED WITH IODOFORM.

BY A. MITRA, L.R.C.P., L.R.C.S.,
CHIEF MEDICAL OFFICER, KASHMIR.

RAJAUL, a prisoner at the Kashmir Gaol, aged thirty-five, received a wound in the hand and forearm on April 12th. He, together with other prisoners, were engaged in breaking stones on a hill close to the city of Sreemugur. A large block of stone came rolling down, and Rajaul foolishly attempted to stop it. Soon after the injury, as he was being carried from the spot to the gaol, it was fortunate that Dr. Neve, of the Mission Hospital, happened to be passing, who took him to his hospital close by, stopped the bleeding, and rendered such help as he thought was necessary. I saw the patient next morning at the gaol, where I had deputed an assistant to watch him. I examined the wound, and found a large lacerated flap, including skin, muscles, tendons, arteries, and nerves, had been separated; the flap commenced four inches above the wrist, extended along the middle of the hand, and curved round the web of the fingers' ends over the head of the metacarpal bone of the ring finger on its dorsal side. The second flap on the dorsum was more lacerated; it commenced at the second phalanx of the thumb, and curved round the ends near the pisiform bone. All the metacarpals except the first were fractured; the third metacarpal was divided into four pieces. It happened to meet Dr. Neve that morning, who remarked: "The wound is one of the severest I have ever seen." Conservative surgery in such a case of lacerated wound with extensive injury of all the tissues can hardly be justified; but as twenty-four hours had already elapsed, I was determined to give it a trial, without, however, entertaining any hope to preserve the hand. I kept the injured parts soaked with corrosive sublimate lotion (seven grains to a pint). On the third day I opened the wound; there was very little discharge. Dusting the wound thoroughly with iodoform, I covered it with oiled silk, and bandaged with corrosive sublimate gauze. The wound was opened the next day, as the temperature of the patient rose to 100·6° F. in the previous evening. There was slight discolouration in the tips of the little and ring fingers. I decided on amputation, not of the forearm but of the fingers. I made an incision, commencing from between the web of the index and middle fingers, carrying it straight down to the pisiform bone and curving round along the dorsum of the hand to meet the point of commencement. Iodoform was used all along. The wound healed in twenty days. The rise of temperature for the first five days ranged from 100° to 101°. The man has now perfect use of the thumb and index fingers. There is no resulting contraction.

Remarks.—This case shows what repairing powers the tissues sometimes possess. It also establishes the great value of iodoform in the treatment of wounds. In my surgical wards, iodoform is used as the chief dressing, and it always secures for me rapid and aseptic healing. Iodoform dusting has been found more efficacious than ointment even with vaseline. My experience has, however, proved to a certainty that disagreeable symptoms often result from iodoform dressing. They are chiefly gastro-intestinal and nervous irritation. But I have never observed iodoformic fever; these internal manifestations do not come to my notice, because I strictly follow the plan of washing the wound before fresh iodoform is used. With this precaution, there is no fear of poisoning. The forty-eight cases given by König,[1] where symptoms of poisoning supervened during the use of iodoform as surgical dressings, were probably treated without this necessary precaution.

HÆMORRHAGE DURING PREGNANCY, PROBABLY DUE TO SEPARATION OF PLACENTA.

By M. G. BIGGS, M.R.C.S., L.S.A.

MRS. M——, aged thirty-eight, mother of seven children, was confined of a healthy boy on Sept. 30th, 1886. There was no hæmorrhage of any unusual kind during the labour. Forceps were used after the membranes had been ruptured, owing to uterine inertia. She has always had tedious labours. Early in January, 1886, she was regular; she then saw nothing until about the middle of February, when it came on rather suddenly and freely whilst she was standing in the shop, her husband being a dyer. From that time up to about a week before the confinement she used to bleed every fortnight or month, and even between these times there was often a blood-stained discharge. In July she sent for me; but rest in bed and the use of gallic acid and digitalis internally set things right for the time, and I heard nothing more of her until the day of labour. She had never been at all like this on any previous occasion. On removal of the placenta one part of the zone was of a much lighter colour than the other, with partly decolourised clots, and these same partially decolourised clots were clinging to the corresponding outer surface of the membranes. The appearance was most characteristic. The sudden onset looks suspicious, but then it was so early in the case when it commenced, before the formation of the placenta.

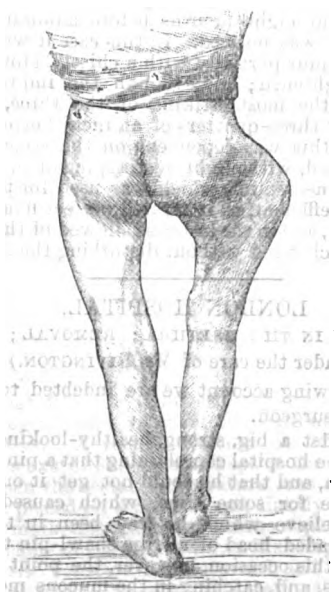
Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum allorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lb. iv. Proœmium.

UNIVERSITY COLLEGE HOSPITAL.

THREE CASES OF BADLY UNITED FRACTURE OF THE FEMUR.



(Under the care of Mr. CHRISTOPHER HEATH.)

THE three cases which follow are interesting, as showing the different plans of treatment carried out in badly united fractures, according to the period which has elapsed since the receipt of the primary damage. We would refer our readers to the remarks appended. We are indebted for the notes of these cases to Mr. Bilton Pollard, surgical registrar.

CASE 1.—E. G——, a boy aged seven years, was admitted into the hospital on August 27th, 1886. His left femur had been broken about its middle by direct violence shortly before admission. There was only half an inch shortening. The fracture was treated with Liston's long splint for two days, and then with Hamilton's splint for three weeks. There was then only a quarter of an inch shortening. The limb was fixed with plaster-of-Paris bandages, and the patient was discharged. Seventeen days later he was readmitted, as the plaster case had slipped and the femur was bent at the seat of the fracture and shortened to the extent of an inch and a quarter. The fragments occupied the positions usually met with in fracture of the shaft of the femur. The patient was placed under the influence of ether, and Mr. Heath bent the bone over the knee to a good position and reduced the shortening to a quarter of an inch by forcible traction. A Liston's long splint with a perineal band was applied. The bone united well in good position, and about a month after it was reset a plaster-of-Paris case was applied and the patient was discharged.

CASE 2.—H. O——, a boy aged twelve years, was admitted into the hospital on Sept. 30th, 1886. He stated that between three and four months ago he fell whilst getting over a stile, and broke his left thigh. The fracture was treated with a Liston's long splint for a month, and afterwards with starched bandages for eight weeks. In the last seven weeks of this time the boy went about on crutches. A simple bandage was then applied. On admission the boy could only walk with difficulty, owing to the left leg being two inches and a quarter shorter than the right. The fragments were firmly united, with their ends overlapping, in the manner characteristic of a fracture of the shaft of the femur. At the junction of the upper and middle thirds of the thigh there was a large swelling on the outer surface of the limb due to the projection of the lower end of the upper fragment. On Oct. 11th the patient was anæsthetised, and Mr. Heath with considerable difficulty succeeded in breaking down the uniting callus. This he did by placing his foot on the swelling above mentioned, and using the extended limb as a lever, by means of which great force was brought to bear on the uniting callus. Forcible traction was then made on the limb, and some of the shortening was by that means overcome. Weight extension was applied to the limb. Two days later, the shortening being reduced to half an inch, the limb was fixed in a Thomas's knee-splint. Five weeks after the bone was reset, the position of the fragments was good, and the shortening was less than half an inch. The limb was immovably fixed in plaster-of-Paris, and the patient was discharged. A month later the plaster-of-Paris apparatus was removed, and the knee, which was very stiff, was moved whilst the patient was under the influence of gas.

CASE 3.—D. P——, a boy aged seventeen, was admitted into the hospital on Nov. 1st, 1886. In 1882 he had suffered

from a fracture of his left thigh, which had united in good position. In November, 1884, he broke his right thigh. It was treated with a Liston's splint for four weeks, and a week later the patient left his bed and began to walk about. His thigh appears to have kept sound till April, 1886, when he occasionally fell down, owing to weakness in it; but he gives no account of any severe injury, though he states that he noticed an increasing deformity of his thigh. On admission his right thigh presented the marked deformity shown in the accompanying woodcut. There appeared to have been a double fracture of the femur, for, in addition to the prominent angle on the outer surface of the thigh, there was another prominence also on the outer surface of the thigh at a point about four inches below the tip of the great trochanter. At this spot the upper fragments appeared to overlap the lower on its outer surface. At the point of greatest deformity the fragments did not overlap one another. The limb was two inches and three-quarters shorter than its fellow. On Nov. 10th Mr. Heath first tried to break the femur in the manner described in the last case, but failed. He then made a small incision on to the most prominent part of the deformed bone, and with the aid of a chisel partially divided it. The remainder of the bone was then broken. The carbolic spray was used during the operation, and the wound was dressed with carbolised gauze. The limb was put up in a

Digitized by Google

Thomas's knee-splint. After the bone was broken the fragments overlapped, and it was found impossible to overcome the displacement entirely, but by increasing the amount of extension force from day to day the deformity was largely reduced. The dressing was changed on the second day after the operation, and weekly afterwards. The temperature remained normal till the eleventh day, when it rose in conjunction with a slight pleuritic attack. Six weeks after the operation the wound was soundly healed, the fragments were united by a large mass of callus, and the limb was in good position, but it was still three-quarters of an inch shorter than its fellow. A plaster-of-Paris splint was applied, and the patient was discharged to the Convalescent Home at Eastbourne.

Remarks.—The three cases now recorded were under Mr. Heath's care at the same time, and they form an interesting group illustrative of the treatment of badly-united fractures. In the first case the fracture was only five weeks old, and the callus was soft enough to allow of its being bent and the bone being brought into good position. In the second case the bone had been broken between three and four months before the patient was admitted, and it was found necessary to employ considerable force to rebreak it. The result was very good, for the shortening of two inches and a quarter, which had entirely crippled the patient, was reduced to less than half an inch. With regard to the third case, it is doubtful whether the deformity which the femur presented was due to the fracture two years previously, or whether it depended on an injury sixteen months later, for it was only about eight months before admission that the great deformity was noticed. In this case it was necessary to divide the femur partially with a chisel before the bone could be straightened; and, though the improvement in this case was the most striking of the three, there still remained about three-quarters of an inch shortening. It is probable that this was dependent on the second fracture, which had united, with slight overlapping of the fragments. The Thomas's knee-splint, which was used for the last two cases, was very efficient, as it secured perfect fixation, facilitated extension, and in the last case allowed of the antiseptic dressing being changed without disturbing the fracture.

LONDON HOSPITAL.

FOREIGN BODY IN THE URETHRA; REMOVAL; REMARKS.

(Under the care of Mr. RIVINGTON.)

FOR the following account we are indebted to Mr. A. W. Burrell, house-surgeon.

On January 1st a big, strong, healthy-looking labouring man came to the hospital complaining that a pin had slipped into his urethra, and that he could not get it out. He had had a stricture for some time, which caused periodical retention, to relieve which he had been in the habit of passing the beaded head of a large shawl-pin through the stricture. On this occasion, however, the point had slipped past the meatus, and, catching in the mucous membrane, he had been unable to extract it, and during the walk of a mile to the hospital it had worked some distance up the urethra.

On examination, the point of the pin could be felt sticking through the urethra into the cellular tissue of the scrotum, in the middle line, just in front of the perineum; while with the finger in the rectum the shaft could be followed through the membranous and prostatic portions into the bladder, into which, however, the head penetrated too far to be felt. As after a little rest and a bath he passed his urine pretty freely by the side of the foreign body, he was left till the morning.

Jan. 2nd.—The point of the pin could now be felt just under the loose skin of the scrotum, with an inch and a quarter of the shaft protruding through the urethra. Mr. Burrell passed down a long pair of urethral forceps, and seized the pin in the urethra; at the same time passing his finger up the rectum, he pressed it up under the arch of the pubis, thus fixing it. Mr. T. N. Thomas then, under Mr. Burrell's direction, stretched the skin over the point, making a nick with a knife on it. He seized the point with forceps, and drew it out until the head stopped at the aperture in the urethra; then he depressed the point, and, reversing the mode of entrance of the pin, easily pushed the head out of the meatus, followed of course by the shaft. A catheter was passed, and some collodion placed on the puncture. The man refused to have his stricture treated, and went out the next day. The pin proved to be a blue steel shawl one, five inches and three-quarters long, with a black glass bead for a head, a quarter of an inch in diameter.

The case is interesting, as showing the position taken up by a long, straight foreign body slipping into the urethra. Thus it lay across the fixed curves of the urethra, the point perforating the penile urethra about one inch in front of the membranous portion.

ST. VINCENT'S HOSPITAL, DUBLIN.

A FATAL CASE OF PARAPLEGIA; NECROPSY; REMARKS.

(Under the care of Dr. QUINLAN.)

P. S——, aged fifty, a stout well-built man, a cabdriver, was admitted on Jan. 6th. He had for the last two years been of very intemperate habits, and on New Year's Day was driving his cab in a state of partial intoxication, when he fell off the box upon the road, which was then hardened by severe frost. He was assisted up to his driving seat, and was able to guide the vehicle home at a walking pace. Arriving home, his trap was put up for him, and he went to bed, as it was thought, to sleep off his potations. Next morning he felt chilly and numbed, and was unable to stand; he got daily worse, and began to speak thickly.

On admission upon the 6th, Dr. Quinlan found the man unable to move hand or foot; the surface of his body was livid, and very cold; and he was unable to distinguish the double points of the sensation compass at all in the lower parts of the body, and in the upper only when they were divaricated over an inch and a half. He had no control over his fæces, and the urine had to be drawn off by the catheter several times a day. His pulse was only 44, and his mouth temperature the clinical thermometer would not register, it being under 95°, its lowest marked degree. Priapism was present. He did not suffer any pain; but all over his sacral region a large bedsore was threatening to form. He got steadily lower and weaker; effusion into the bronchial tubes set in; and he died on the afternoon of Jan. 9th.

The post-mortem examination was made twenty hours after death by Mr. Coen, resident medical officer, who removed the calvaria, the occipital bone, and the whole covering of the back of the spinal canal, thus allowing the brain and spinal cord to be removed in their entirety. There was no injury of the vertebral column, but intense and general congestion of the vascular covering of the brain and of the spinal cord, which were pinky-red over the whole extent. There was no softening; but on making sections of the spinal cord, spots of congestion, almost resembling small hæmorrhages, were to be found scattered throughout its whole substance. On the sacral region was a circular, yellowish discolouration, nearly the size of a dinner-plate, and surrounded by a well-marked commencing line of separation, and which before many hours would have become a slough.

Remarks by Dr. QUINLAN.—In this case the cerebro-spinal inflammation was evidently caused by the patient falling on his back upon the hard road. He apparently fell in this way, for his head was not injured, and, from his inebriated condition, he does not seem to have put out his arms to save himself. The severe cold of the weather and his chronic alcoholism no doubt contributed to the fatal result. The case was from the beginning hopeless, from the general involvement of his nervous system, both cerebro-spinal and sympathetic, as evidenced by the symptoms above described.

THE COUNTESS OF DUFFERIN'S FUND.—The second annual report of the central committee of the National Association for Supplying Female Medical Aid to the Women of India has just reached England, and contains the following information as to the financial state of the fund:—The central fund at the beginning of last year brought forward a balance of 146,188 rupees. Since that date 76,109 rupees have been received. The annual income of the central fund is estimated at 19,450 rupees, which is partly made up of 9750 rupees interest on investments, of 2700 rupees from annual subscribers, and of contributions from the branches, which in 1886 amounted to 2700 rupees. This income, Lady Dufferin states, is very far below the exigencies of the situation; and she earnestly appeals for support from the people of England in this the Jubilee year.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Annual General Meeting.—President's Address.

THE annual general meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair. Mr. R. W. Parker and Dr. Angel Money were appointed scrutineers of the ballot.

Dr. CHEADLE read the report of the President and Council. It showed that the financial position and general prosperity of the Society were in a favourable state.

The report of the honorary librarians states that the additions to the library during the year 1886 consist of 879 works, including pamphlets, but not including Transactions, journals, and other periodical publications; 638 of these additions have been obtained by purchase and 241 by donation. These latter include 25 works in 100 vols. presented by Dr. Lauder Brunton, and 32 old books given by Mr. Charles Hawkins. In the 638 works added by purchase is included a bound collection of 420 "Thèses de Médecine," put together by the late Dr. C. Parrot. The total number of works in the library, Dec. 1886, was 30,282. During the past year 3587 books have been borrowed from the library. The number of visits of Fellows has been 4574. The collection of portraits of members of the medical profession has been enriched by the addition of 63 new portraits.

The PRESIDENT read his address. It consisted, as is customary, of the obituary memoirs of all those Fellows of the Society, deceased during the past year, and occupied an hour and a half in the reading, thus proving the numerous losses the Society had sustained by death since the last annual meeting.

Dr. CHARLES WEST proposed and Mr. J. H. MORGAN seconded the adoption of the report of the Council.

Sir JOSEPH FAYRER proposed and Mr. COWELL seconded the vote of thanks to the President for his address.

Mr. R. BARWELL proposed and Dr. PAYNE seconded the vote of thanks to the retiring vice-presidents and members of the Council: Dr. J. W. Ogle, Mr. Berkeley Hill, Dr. Buzzard, and Dr. Church.

Dr. O. STURGES proposed and Mr. HAWARD seconded the vote of thanks to the retiring treasurer, Dr. Radcliffe.

The following is the list of officers unanimously elected for the ensuing year:—President: Mr. G. D. Pollock, F.R.C.S. Vice-Presidents: W. H. Dickinson, M.D.; W. Ogle, M.D.; A. E. Durham; T. Smith. Treasurers: C. J. Hare, M.D.; Timothy Holmes. Secretaries: W. B. Cheadle, M.D.; Howard Marsh. Librarians: Wilson Fox, M.D., F.R.S.; J. W. Hulke, F.R.S. Members of Council: J. Cavafy, M.D.; Sir T. Crawford, K.C.B., M.D.; J. F. Payne, M.D.; R. D. Powell, M.D.; A. E. Sansom, M.D.; H. C. Rose, M.D.; Marcus Beck; H. T. Butlin; J. McCarthy; C. S. Tomes, F.R.S.

CLINICAL SOCIETY OF LONDON.

Paralysis of Left Leg from Subcortical Disease.—Rheumatic Hyperpyrexia successfully treated by the Cold Bath. Epilepsy following an Injury to the Leg.—Profuse Hæmaturia in connexion with Granular Kidneys.

AN ordinary meeting of this Society was held on the 25th ult., Dr. W. H. Broadbent, F.R.C.P., President, in the chair.

Dr. HUGHLINGS JACKSON read a paper on a case of Paralysis of the Left Leg from Subcortical Disease, with Cancer and Fracture of the Left Femur. A woman aged fifty-two was admitted on Dec. 28th, 1885, under Dr. Hughlings Jackson's care, for paralysis of the left leg, which had come on suddenly on Dec. 7th, whilst she was standing at her work. The knee-jerk on the paralysed side was greatly exaggerated, and there was foot-clonus; there was no defect of sensation; no morbid changes in the fundi. On Dec. 30th, whilst she was being lifted from the bed-pan, the left femur broke just below the great trochanter. Death occurred on Jan. 19th. At the necropsy there was found cancer of the left femur, of the ovary, and of the brain. The brain was examined by Dr. James Anderson, who found several growths in it, one, accounting for the paralysis of the left leg, being in the region of Ferrier's leg centre.—Dr. BROADBENT said the case was interesting from more than one point of view. The nodule to which the paralysis corresponded might have been described from other points of view than the internal aspect. The early occurrence of ankle-clonus and exaggerated knee-jerk was hardly in accord with the sclerotic theory of these phenomena.—Dr. BREVOR said that Messrs. Schäfer and Horsley first discovered that the posterior part of the marginal convolution was a part of the leg centre. The absence of fits might be explained by the nodule not having implicated the cortex. He was working with Mr. V. Horsley at the minute arrangement of the leg centre, and found that the toes were represented in the parietal lobule, which was not involved in Dr. Jackson's case. With regard to the fibres of the internal capsule, those from the leg descended in the hinder part of the internal capsule, as had been ascertained by experimental stimulation of the exposed fibres in the monkey.

Dr. CARRINGTON read a case of Successful Treatment of Hyperpyrexia in Acute Rheumatism by the Cold Bath. He said that although there was nothing new in the case he brought forward, still he thought it was well to put such cases on record in order to accumulate a body of evidence such as would enable medical men to combat the prejudice existing amongst the friends of patients against the employment of a remedy which afforded the only chance of safety in this desperate complication. The patient was a medical student, aged twenty-three, strong and muscular, and hitherto in perfect health. He had been ill with what was apparently a mild attack of rheumatism, for which he had been treated by salicylic acid. He was so far recovered that he had left his bed, and on the evening of Oct. 31st had received the visits of his friends. He passed a good night, and there was nothing to excite attention next day, but on taking his temperature next morning about 12 noon, quite as a matter of routine, it was found to be 107°. Dr. Carrington saw him soon afterwards, and then found the temperature to be 106°. He was, as soon as practicable, removed to the private ward of Guy's Hospital, but in the journey had become noisy and delirious, and by the time he had been placed in bed he was quite livid, unconscious, and generally convulsed. His temperature was then found to be 109·8°. The necessary arrangements had been previously made, and he was at once placed in a bath at a temperature of 70°, which was as rapidly as possible cooled down by ice; large quantities were used, but the body heat was so great that there was great difficulty in lowering the temperature of the bath. Pouring ice-cold water on the patient's head had a beneficial effect. A rectal injection of fifteen grains of antipyrin was exhibited. He was kept in the bath for a full hour, and when the rectal temperature was 102·4°, he was removed and placed on a blanket and lightly covered by a sheet. Then marked tetanic convulsions supervened, and he gradually became quiet, and at 7 P.M. his temperature fell to 97·2°. At 8 P.M. consciousness returned, and he took a pint of milk, and at 10 P.M. he was quite rational. During the next day he remained comfortable, and took twenty grains of salicylate of soda every two hours, but his temperature again arose, and at 12 P.M. it was 103·8°. He was given fifteen grains of antipyrin by the mouth, but at 2 A.M. the temperature was 105·2°, and the ice-bath was again employed for fifteen minutes. He was taken out when his temperature had fallen to 101°, but at 6 A.M. it had again risen to 105·4°, and the bath was again had recourse to for a similar period. After this he slept well, but at 2 P.M. the temperature had reached 105°, and he was bathed again for forty minutes. From this time the temperature never again rose to any extent; it was for the most part normal, but on one occasion with a return of the articular pain it reached 101°. After the third bath salicine was substituted for sodic salicylate, in twenty-five grain doses every two hours. After two days he took it every three hours, and the dose was gradually reduced. With an interruption due to the slight relapse, the patient made an uninterrupted recovery from this time, and left the hospital quite well. The experience of the case seemed to be that within the limit of collapse, prolonged immersion was more effectual than shorter and more frequent baths.—Dr. HALE WHITE remarked on the uselessness of the antipyretics in this case, and he thought that the way in which the drugs act must be different in different cases. The class of pyrexias influenced by antipyrin and other antipyretics were, perhaps, of a different nature. Referring to a case of inexplicable pyrexia that ultimately got perfectly well, he said that neither antipyrin, salicylate of soda, nor

Digitized by Google

quinine had any influence over the course of the fever.—Dr. BROADBENT remarked on the occurrence of convulsions in connexion with this case; he had not observed convulsions during the rise of temperature; perhaps the removal of the patient to the hospital might have had some share in their causation. In cases of hyperpyrexia in typhoid fever, he had witnessed the development of remarkable opisthotonos, which had no relation with the general convulsions. He inquired whether shivering was taken as an indication for removal of the patient from the bath. He had known hyperpyrexia to supervene during the administration of large doses of salicylates, but in one case pericarditis developed. He supposed that the præcordial murmur in Dr. Carrington's case was of hæmic origin, and partly due to myocardial dilatation, not to pericarditis.—Dr. HUGHLINGS JACKSON said it was important to note whether convulsions were tonic first and clonic afterwards, or whether they occurred in confused alternation.—Dr. STEPHEN MACKENZIE had seen four cases of hyperpyrexia in private practice. In one of rheumatic fever he employed ice and water till the temperature became normal, when the patient was seized with complete tetanic rigidity, in which he was only partially conscious, and became of deathly pallor, reminding one of the picture at Brussels of the man risen from his coffin after being interred as dead from cholera. It was found necessary to employ stimulants, but the man died ten hours later. In private practice he had had no case of complete recovery, thus showing the importance of careful nursing and proper appliances for such cases. In Dr. Wilson Fox's first case the balance between hyperpyrexia and subpyrexia was very marked, cold and stimulants being alternately and concurrently required. No clonic convulsion was observed with the tetanic state.—Dr. BROADBENT said that the convulsions observed by him were of an irregular clonic character, in which there was no recognised phase of rigidity. No clonic convulsion occurred in association with the tetanic opisthotonos to which he had referred.—Dr. CARRINGTON said that it was only on removal from the bath that the tetanic state without clonic spasms developed. The first bath lasted one hour. Drugs, so far as one could tell, had no beneficial effect.

Dr. HADDEN brought forward a case of Epilepsy after Gunshot Wound in a man aged thirty-two, who was under Mr. Croft's care at St. Thomas's Hospital. There was no family history of epilepsy. In 1872 he was wounded in the left calf, and several shots were extracted. In six or seven weeks the wound was quite healed. Four months after the injury he began to have fits. For nine months they were occasional, but afterwards he had as many as twelve daily. The sciatic nerve was then stretched, and the fits ceased for thirteen years. They recommenced seven weeks before admission into St. Thomas's, when he fell to the ground from a ladder unconscious. During the week preceding admission he had eight or ten daily. The fits began with a sharp twitching pain in the scar in the left calf; then there was a creeping, heating sensation passing up the leg and left side of the body to the head. The left side then became convulsed. The pupils were immobile, and the conjunctivæ insensitive. Finally, there were some general convulsive movements, and then rapid return to consciousness. The tongue was not bitten, nor were the evacuations passed. The scar was somewhat tender, and when pressed he would at times have the sensation passing up the body, and sometimes a convulsion. Occasionally in the seizures he would roll about in bed, and sometimes there was opisthotonos. An attempt was made to stretch the sciatic nerve by extreme flexion of the hip, but the result was a violent convulsion. A few days later the nerve was exposed and freely stretched. The fits stopped for nine days. He then had occasional seizures—sometimes one a day, sometimes one every other day. Two occurred whilst the splint was being bandaged to the leg, and one during removal of the splint. The man wrote four months later to say that he had had no convulsion since he left the hospital, but he suffered from severe paroxysmal pain in the left calf, followed by the "fitty" sensations. There was no doubt that the attacks were genuine, the condition of the pupils and conjunctivæ and other points proving this. The interest of the case has reference to Brown-Séquard's and Victor Horsley's experiments on guinea-pigs. Epilepsy was induced by these observers after injury to the sciatic nerve. There is usually a latent period of from two to six weeks. In the man the incubation was four months. Opisthotonos occurred in the patient, as in the case of guinea-pigs.—Mr. BOWLBY related the case of a man who had received a charge of shot in the leg about eighteen months before he was first seen. The fits had been increasing in frequency and force, and were always characterised by pains beginning in the wounded leg in the area supplied by the musculo-cutaneous nerve, of which an inch and a half was excised, and after two or three days the fits ceased, and the wound healed soundly after having suppurated. The man remained five years without recurrence of the fits. Some shot under the skin were then found and removed, with the result of temporary stoppage of the fits. After a time Mr. Willett practised stretching of the sciatic nerve; the fits thereafter continued for awhile, but then ceased, and there had been no further occurrence.—Dr. H. JACKSON referred to the case of a boy brought before the Society last November, who had fits whenever his head or face was touched—a case like that of a guinea-pig rendered epileptic by injury of the sciatic nerve or spinal cord.—Dr. CARRINGTON alluded to cases of trephining for epilepsy, and said that recovery sometimes followed the mere operation.—Dr. ANGEL MONEY considered, with Dr. Hughlings Jackson, that in most cases of epilepsy there was an epileptogenous zone in some part of the periphery of the nervous system. Probably there were various kinds and modes of excitation of this area, and these were the exciting causes of the attacks of epilepsy. Reference was made to a case of genuine idiopathic epilepsy in which the ingestion of a stick of chocolate was sufficient to excite a genuine attack, which began with a sensation of frightful hunger at the pit of the stomach a few minutes after eating the chocolate, was soon followed by a rushing sensation to the head, and this was succeeded by loss of consciousness, in which convulsions of tonic, clonic sequence might be observed.—Dr. BROADBENT referred to his own experience of like cases. In one, that of a girl with a whitlow, violent epileptiform convulsions were of frequent occurrence, but on the removal of dead bone they entirely ceased. Another case of reflex epilepsy was that in which there existed a piece of glass in the ulnar nerve, palpation of which was invariably followed by the occurrence of a fit. These cases differed from ordinary epilepsy in that they might occur at any age. Cases of idiopathic epilepsy in which fits occurred several times a day were of rare occurrence. The extreme frequency of the fits was another feature of the cases under discussion. He concurred with Dr. Hadden in thinking that removal of the scar rather than stretching of the nerve was the better treatment to adopt.—Dr. HADDEN, in reply, thought the class of cases of epilepsy under discussion partook of the nature of tetanus resulting from a wound. He was much struck by the resemblance between Mr. Bowlby's and his own case.

Mr. ANTHONY BOWLBY read a paper containing the records of three cases of Hæmaturia in connexion with Granular Kidney. The first was that of a man aged seventy-three, who was admitted into St. Bartholomew's Hospital suffering from enlargement of the prostate and hæmaturia. His death, which occurred within twenty-four hours, appeared to be chiefly due to the exhaustion caused by the loss of blood. A post-mortem examination showed an enlarged prostate and dilated bladder, containing several ounces of almost pure blood. The kidneys were small and granular. Their pelves and the ureters contained blood, and in the renal substance there was much blood extravasated. Microscopical examination showed that the hæmorrhage had occurred both into the renal tubes and into the cellular tissue of the gland. The second case was that of a man aged forty-nine, who had long suffered from stricture of the urethra and difficult micturition, and who for three months previously to admission into St. Bartholomew's Hospital had passed considerable quantities of blood with his urine. He had many of the ordinary signs of interstitial nephritis, and, in addition, passed a great deal of blood. On his death, from uræmia, no cause of hæmorrhage was found, except in the kidneys. These were small and granular, and contained a little bloody urine. The third case, a man aged sixty-four, was admitted on Feb. 3rd, 1886, with profuse hæmaturia and pain in the loins. After losing much blood for several weeks the hæmaturia ceased. The urine when clear contained albumen. There was some albuminuric retinitis and some opacity of one lens. Attention was drawn to the fact that the subject of hæmaturia in connexion with granular kidney has received little attention, that no cases of profuse hæmaturia of this nature have been previously recorded, and that no post-mortem examinations have been described. It was pointed out that in one of the

Digitized by Google

patients who was the subject of this paper the hæmorrhage was so profuse as to be mistaken for vesical bleeding, and in the others the diagnosis had to be made from other of the more recognised causes of renal hæmorrhage, especially calculus. It is in connexion with this question of diagnosis that these cases are of importance. Lastly, it was stated that simple interstitial nephritis, independently of dilatation or absorption of the renal substance was often found as the result of obstruction to the outflow of urine.—Dr. CARRINGTON considered the cases to be of great rarity, and remarked on the existence of obstruction in the urinary passages.—Mr. R. J. GODLEE referred to the fact that in some of the cases instrumentation had been practised for the relief of retention of urine. Such instrumentation of the urinary passages would be likely to be followed by acute attacks of hæmaturia and renal congestion.—Dr. HADDEN referred to two cases of profuse hæmaturia, in which the diagnosis had been overlooked and in which the kidneys were found after death to be the seat of large hæmorrhages.—Dr. MAGUIRE considered that cases of hæmaturia in association with granular kidney were not of great rarity, and the hæmaturia seemed to be followed by improvement in the patient's general condition.—Dr. BROADBENT thought that profuse hæmaturia was rare in cases of granular kidney. In one case the patient had had uræmic convulsions, from which recovery took place, and death occurred some years later from hæmaturia, the cause of which was bleeding from an artery running in the wall of the pelvis of one kidney.—Mr. BOWLBY, in reply, said that catheters had been passed in one case but not in the others, and the circumstance that all the cases occurred in the surgical wards showed the profuseness of the hæmorrhage and the overlooking of the nature of the cases.

The following living specimens were shown:—Dr. Arthur Davies: A case of Myxœdema in the male, aged thirty-eight, of seven years' duration, and a case of the same disease in the female. Mr. A. E. Barker: A case of Fracture of the Upper Cervical Vertebræ, causing Right Hemiplegia, from which the patient had completely recovered.

MEDICAL SOCIETY OF LONDON.

The Treatment of Syphilis by Mercury.

AN ordinary meeting of this Society was held on Monday, Feb. 21st, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Mr. E. MILNER read a paper on the different modes of administering Mercury in Syphilis, and the indications for their application. He gave some of the results of his experience of twelve years' out-patient practice at the Lock Hospital, with a view of arriving at some definite conclusion as to what preparation of mercury should be employed in order as rapidly as possible to get rid of the visible signs of syphilis. In the majority of cases blue pill is as good as blue ointment and green iodide as Donovan's solution; but even in these cases he thought that more accurate and more careful observation in practice would render such an admission unjustifiable. He dealt with three of the most common methods of administration: 1. Some of the cases in which green iodide should be used. 2. Some of the cases in which inunction should be practised. 3. Some of the cases in which the vapour of calomel should be employed. Of all the syphilitic rashes, the most evident, most persistent, and perhaps the most difficult to combat, is the vesicular syphilide. It most frequently occurred in light-haired women who drank large quantities of wine as distinguished from spirits. The vesicular may be associated with an early tubercular syphilide, and this usually in dark-haired people during cold weather, and in the underfed and underclothed patients of anxious temperament. In the first of these two classes green iodide with Donovan's solution, in large doses, was most valuable; in the second class the inunction of the German preparation of blue ointment has excelled all other methods of treatment. In billiard-markers, some actors, barmaids, actresses, and commercial travellers, who drink freely and sit up late, the syphilitic rash is apt to become angry, excessively red, and marked. In spite of the diarrhœa, give green iodide in large doses. Donovan's solution, with soda and iodide of sodium will assist, the latter salt being better than the potassic salt. The keeping of late hours materially influences the character of syphilitic eruptions. These people often have a thick oily perspiration which interferes with the nutrition of the skin and initiates the manifestations of syphilis; it was perhaps one of the causes of the so-called gouty character of the syphilide. Barmaids present the reddest and most angry syphilitic rashes, and the lesions are most difficult to treat. Such might be named "barmaid's syphilis." For these cases green iodide of mercury was the best preparation. In those who drink and never take care of themselves green iodide was next best to inunction, and would probably, under all the circumstances of the case, prove most efficacious. Green iodide of mercury is the most available remedy with patients who sit up late, who have light hair, and drink freely. The typical case for the green iodide would probably be the light-haired degenerated lady who sits up all night playing the piano at suburban parties, who eats but little, but refreshes herself frequently and takes a little brandy before retiring to rest. The German ointment is less strong, contains more suet, and is harder and preferable to that of the British Pharmacopœia. It salivates severely less frequently, and produces a more permanent effect. Many cases of primary syphilis in healthy, abstemious, light-haired men will be benefited by mercurial inunction. Patients with dark hair treated in this country with inunction, though they may almost avoid syphilides, may suffer severely from a form of sloughing sore-throat. Inunction in the late stages is a refuge for the destitute, but rarely it may give gratifying results. Large syphilitic testicles, secondary gummata, and syphilitic nervous disease may yield like magic to inunction. Inunction is most useful in the early stages with healthy, light-haired, abstemious patients with a primary sore, and the German ointment will almost certainly cure the distracted married man who has had syphilitic lumps for many years. To rapidly get rid of sores the local administration of mercury in the form of the vapour of calomel is of material assistance, whether the sore be the smooth, flat, indolent button, or accompanied by destructive ulceration of the glans penis. The vapour is also valuable in ulceration of the extremities, especially the legs, syphilitic in their origin, but frequently associated with a weak state of constitution, or, more frequently still, associated with a too rapid or indiscriminate administration of mercury. In certain cases, where mercury cannot be administered internally, the vapour of calomel locally applied is of great assistance, as also in the red, angry, tubercular eruption on the forehead along the line of the hat leather, and in the destructive ulceration of the fauces in late secondary syphilis.

Mr. BRUDENELL CARTER referred to the syphilitic lesions of the eye, especially of the retina, which were met with in the tertiary stages, and especially in those individuals in whom the mercurial treatment had been inadequately carried out.

Dr. DRYSDALE could not agree that mercury was the only treatment of syphilis, and spoke of the probable germicide effect of mercury and iodine.

Dr. LAUDER BRUNTON said that it was very difficult to explain the *modus operandi* of mercury and iodides in syphilis, for the pathology of this disease was still imperfectly known. Perhaps they acted as germicides.

Mr. DE MÉRIC considered inunction was an uncleanly method. He had seen many cases of tertiary syphilis which were benefited by mercury.

Dr. ALTHAUS alluded to other methods of introducing mercury than those given in the paper. He spoke of hypodermic injections, lanoline inunction, and the oleates, all of which methods he had employed with success.

Dr. T. K. SALTER had had a syphilitic chancre on the finger, treated for nine months by calomel baths, and without any secondary symptoms having appeared.

Mr. MILNER, in reply, alluded to the baneful influence of large doses of iodide of potassium. Mercury was practically indispensable.

The following is a list of the names of Fellows nominated for office by the Council for the ensuing year:—President: J. Hughlings Jackson, M.D., F.R.S. Vice-President: T. L. Brunton, M.D., F.R.S.; Sir W. Mac Cormac, D.Sc.; T. H. Green, M.D.; J. Knowsley Thornton, M.C. Treasurer: A. E. Durham. Librarian: W. H. Allchin, M.B., F.R.S.E. Honorary Secretaries: Samuel West, M.A., M.D.; Bernard Pitts, F.R.C.S. Secretary for Foreign Correspondence: Felix Semon, M.D. Council: R. Brudenell Carter; H. H. Clutton; W. Harrison Cripps; J. N. C. Davies-Colley; S. H. Dawson, M.D.; D. W. Finlay, M.D.; Francis Fox; J. Langton; J. Lowe, M.D.; R. Macguire M.D.; R. P. Middlemist; J. H. Morgan; W. M.

Ord, M.D.; R. Douglas Powell, M.D.; W. Pye; J. P. Richards; A. J. MacConnel Routh, M.D.; T. Gilbart Smith, M.D.; C. Theodore Williams, M.D.; S. W. Wyman, M.D.

Excision of Half of Larynx.—Tuberculosis of Fauces.—Dislocation of both Hips.—Excision of Hip.—Trephining for Cerebral Abscess.

A clinical meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Mr. LENNOX BROWNE exhibited a patient from whom he had ten weeks previously excised the left half of the Thyroid and Cricoid Cartilage with the corresponding arytenoid, vocal cord and internal soft parts, on account of unilateral epithelioma in a male patient aged 61. The following points were emphasised:—1. Use of the raspatory for removing the tissues external to the cartilage as the surest safeguard against hæmorrhage, as lessening the chance of septicæmia, and ensuring speedy recovery of the power of swallowing, &c. 2. The use of Hahn's tampon cannula. 3. The use of perchloride of mercury in solution, and of corrosive sublimate gauze in preference to iodoform, as dressings for the wound. 4. The not too quick closing of the external wound, with the view of prolonging functional rest of the larynx without the irritation of a tracheotomy tube. The patient spoke with a fair gruff voice, and was able to resume his occupation, but Mr. Browne considered that it was too early a period yet to speak as to the freedom from recurrence.

Mr. LENNOX BROWNE also showed a young woman, aged twenty, married, and the mother of three children who was the subject of Tuberculosis of the Fauces and Pharynx, extending to the posterior wall of the larynx and slightly involving the right arytenoid cartilage. The lung condition showed only incipient phthisis, but bacilli of tubercle were plentiful at the seat of ulceration. The patient had suffered on admission into the hospital on December 4th from dysphagia in such an extreme degree that she preferred not to take food. According to the method advised by Krause, of Berlin, the diseased surface, previously anæsthetised by cocaine, was scraped, and solutions of lactic acid, 20, 40, and 60 per cent., were applied daily for twenty-one days. At the end of that period acute inflammation took place, on recovery from which the dysphagia was found to be absolutely relieved. In reply to Dr. Angel Money, he said that the case was regarded as tubercular by all who had seen it, and the typical bacilli were discovered.

Mr. T. PICKERING PICK showed a boy aged eleven with Dislocation of both Hips, as the result of softening of both capsular ligaments. The legs were distorted and deformed, and he was unable to stand; the right thigh was apparently lengthened, flexed, abducted, and rotated outwards; the left thigh seemed to be shortened, flexed, adducted, and rotated internally. The boy had suffered from acute necrosis of the tibia, and the resulting illness had led to the adoption of an abnormal position of the legs so as to relieve pain; from this dislocation had resulted. He had performed osteotomy on both femora with a view to obtaining better positions. Reference was made to Mr. Barker's case of dislocation occurring in typhoid fever as the result of effusion into the hip-joint and softening of the capsule.—Mr. WM. ADAMS said that double osteotomy was the best operation that could have been done for the boy. He spoke also of Rawdon's operation of excision of the head of the femur. He was not certain of the mechanism of the dislocation that occurred in continued fevers. Was the capsule torn or merely distended?—Mr. J. H. MORGAN thought that infantile arthritis might lead to dislocation as well as rheumatic fever. In one case of upward and backward dislocation, the head of the bone was found to be perfectly healthy and movable, the acetabulum was filled with granulation tissue, the capsule tense and stretched over the displaced head, and the teres was destroyed.—Mr. WALTER PYE thought that spontaneous dislocation might occur as the result of pyæmic arthritis.

Dr. A. ROBINSON showed a case of Excision of the Hip in a woman aged forty-five. She had been suffering previously from pyæmic joint affections. The right leg was shortened and everted; there was a sinus discharging freely on the outer side. There was a dislocation on to the dorsum ilii, where the head, denuded of its cartilage, was embedded in indurated tissue. The head and surgical neck were excised, and the final result was good, the patient having a movable limb and being able to walk.—Mr. WM. ADAMS thought the case a very successful one.

Dr. WHITELAW BOURNS showed two cases of (?) Ichthyosis Hystrix, in one of which the affection of the right leg only began four years ago in a woman aged seventy-one.

Mr. J. BLACK read a case of Trephining for supposed Abscess of the Temporo-sphenoidal Lobe. The patient was a man aged twenty-two, whose illness began with vomiting and shivering, and continued with rigors and high fever. He had suffered from otorrhœa for many years. There was a perforation of the membrana tympani and there had been a sinus leading into the mastoid cells. The cells were perforated and free drainage established, without much relief. A few days later the trephining was performed, the dura mater was laid open, and the brain pierced, without result. A day later fresh piercings in different directions were made, but no abscess was detected and the rigors continued. Quinine in large doses, stimulants, and nourishing food were given, and in the course of two weeks the patient had improved considerably, when the rigors returned. Optic neuritis was not detected. The patient ultimately completely recovered. He inquired whether the operation was justifiable under the circumstances. Reference was made to papers by Mr. Barker, Mr. Hulke, and Dr. Greenfield.

Mr. H. ALLINGHAM, jun., showed a case of Fracture of the Lower End of the Right Humerus, with involvement of the median nerve in the callus, and consequent neuritis with paralysis. It was that of a boy aged twelve, and he proposed to cut down by the nerve and liberate it.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, Feb. 9th, Inspector-General Lawson in the chair.

A paper by Inspector-General John MACPHERSON was read, entitled a Memorandum on Notices of Cholera in India before 1817, of which the following is an abstract. The object of this paper is to show that Dr. Semmelinch in his recent history of cholera before 1816-17, and still more Colonel Yule, in his admirable Anglo-Indian Glossary, have made some additions to our knowledge of the diffusion of cholera in the East in early times. Dr. Semmelinch points out that *bort* was the name applied by the Dutch in the east to choleraic attacks, although he does not believe that malignant cholera existed in the East before 1816-17, as all accounts of the disease before that date are unsatisfactory to his mind, owing to their being incomplete in the enumeration of the symptoms of the disease. However, we have positive evidence through him, and still more through Colonel Yule, that cholera of the worst type occurred in Anaca in the Bay of Bengal, in 1602, that *bort* occurred in Ceylon in 1679, and cholera in the Isle of Bourbon in 1716, and further quite possibly cholera in China in 1517. In almost all cases where captains of ships, or travellers, or doctors have mentioned the diseases of the East, they have, in addition to the usual ones of the country, mentioned a certain disease called *mordexin* or *mort de chien* of the French, noted for its sudden onset and rapid course. This was doubtless Indian cholera—sometimes sporadic, sometimes epidemic.

A paper was read by Mr. JOHN MOIR on the Statistics of the West Ham Small-pox Hospitals during the Epidemic of 1884 and 1885. He stated that during that period he attended 1211 cases in the Guardians' Hospital and 303 cases in the Local Board Hospital, with a total mortality of 280 (18·4 per cent.); and the tables compiled by him showed that the mortality after revaccination, with the exception of one case of pneumonia, from which the patient was suffering on admission, was *nil*; after primary vaccination with three or more good marks, 4 per cent.; with from one to two marks, 15 per cent.; in the imperfectly vaccinated, 29 per cent.; in those said to be vaccinated, but without evidence, 44·6 per cent.; and in the admittedly unvaccinated, 52·66 per cent. As to the question of protection by vaccination, it was in exact ratio to the efficiency of the vaccination, and revaccination afforded practical immunity from confluent small-pox and death from small-pox. The deaths from small-pox in West Ham were 259 in 1884 and 563 in 1885, whereas in 1886 there were only 3. A house-to-house visitation carried on by Dr. A. E. Kennedy led to a great increase in vaccination and revaccination, as during the period in question, from March 30th to May 14th, 1885, the public vaccinators in West Ham revaccinated 2978 persons, besides vaccinating 515 over the age prescribed by the Vaccination Act, with a large increase

Digitized by Google

in the number of primary vaccinations. It appeared from Dr. Kennedy's report to the West Ham Board of Guardians in May, 1885, that, in a population of close on 150,000, 98·6 per cent. were found to be vaccinated. But the chief benefit was the increased impetus given to vaccination, and the fact that there were only 3 deaths from small-pox in 1886 was greatly owing to this house-to-house visitation. Another feature brought out by this epidemic was the increase in the number of cases round the hospitals area. The report of Mr. Power to the Local Government Board, printed by the West Ham Board of Guardians, shows that in the three-quarters of a mile radius (used for the reason that it includes the whole of the built-upon area of Plaistow, in which the hospitals were situated, and leaving a zone comparatively sparsely populated), in the six months, Dec. 1883 to June 21st, 1884, this hospital area suffered a rate of small-pox mortality ten times greater than that of the remainder of the district; in the two months and a half, June 22nd to August 30th, 1884, a period corresponding to the normal seasonal decline of epidemic small-pox, West Ham suffered about the same amount of fatal small-pox as in the preceding six months, but the small-pox mortality in the hospital area was smaller, but still nearly twice as great as in the remainder of the district; in the next six months it increased again to over three times that of the rest of the district. There was a large number of hæmorrhagic cases in hospital (fifty-seven), mostly coming from the insanitary and over-crowded districts. The tables showed that the largest number of cases occurred between the ages of fifteen and thirty years, proving the necessity for successful revaccination. Of the 1514 cases, 55 were under two years of age, 18 being vaccinated, with 2 deaths; 4 had small-pox and vaccination concurrently, with 3 deaths; and 33 were unvaccinated, of whom 27 died.

In the discussion which followed, the President, Dr. Dickson, Surgeon General Murray, Inspectors-General Lawson, Lilburne, and Lloyd, Surgeon-Major Pringle, Drs. Thorne and Willoughby, and Mr. Shirley Murphy took part

MANCHESTER PATHOLOGICAL SOCIETY.

The following is a brief record of the proceedings of the meeting on Jan. 19th, Dr. J. Dreschfeld, President, in the chair.

Discussion on Diseases of the Hip-joint in Children.—Mr. G. A. WRIGHT opened the discussion, and after reference to a few points in the anatomy of the joint, he proposed five headings as the subjects for debate, premising that he took for granted the tubercular nature of the complaint. 1. The seat of the primary lesion was held to be nearly always in the bone, as an articular ostitis or affection of some part of the epiphysis, the epiphysial line, or the calcar femoris. The relation between the anatomy of the joint and the seat of the lesion was discussed, and the question of the effects of injury alluded to. A case of synovitis was mentioned as being the only instance in over a hundred cases examined. 2. It was almost impossible to determine the frequency of primary acetabular disease, though the existence of pelvic mischief could usually be ascertained. 3. Necrosis of the femur was said to be present in about 17 per cent., of the acetabulum in about 22 per cent., of cases that had reached the stage of abscess. Total epiphysial necrosis and the question of diastasis were discussed. The mere removal of sequestra was held to be insufficient on the ground that the specimens showed tubercular ostitis round the sequestrum cavity, and this would be left behind. The difficulty of finding the presence of sequestra without section of the bone was also pointed out. 4. The probability of recovery of the bone in the specimens shown was decided against, on the ground that no specimen showed any sign of repair except one in which the whole epiphysis had been removed by natural processes, since it was observed that until this occurs relapses are probable even if temporary quiescence is procured. 5. On pathological grounds the conclusion was that excision is the proper treatment. Between fifty and sixty preparations were shown to illustrate the various features of hip disease and the points indicated in the address.—Mr. F. T. PAUL (Liverpool) agreed with Mr. Wright in placing the origin of the disease most frequently in the bone, and from repeated microscopical examination of typical cases, considered that pulpy disease of the joints was always tubercular. He regarded it as a primary rarefying or tubercular ostitis, commencing in the neighbourhood of the joint, and secondarily involving the synovial membrane. He did not think that in the hip-joint the simple removal of sequestra was sufficient, but believed rather that, since the mischief so frequently began in the head of the bone, the proper treatment was to excise the head and neck only at an early stage—an operation which was frequently followed by primary union and a movable joint. In the later stages excision was very unsuccessful, and he preferred expectant treatment.—Mr. A. W. STOCKS thought that the characteristic position of the limb in incipient hip-joint disease, and the favourable result of early and judicious treatment without operation, combined with the fact that forcible distension of the joint in the dead subject produced a similar distortion, threw a good deal of doubt upon the theory that hip-joint disease commenced, as a rule, in the substance of the bone.—Dr. WM. THORBURN said that Mr. Wright had proved the osseous lesions to exist in such cases as he thought required excision, but he would ask what was the proportion of cases excised to those treated without operation, and whether Mr. Wright held that the lesions were similar in the large number of cases which it is possible to cure by rest, &c.?—Mr. WRIGHT, in reply, said that the fixed position of the limb in abduction and flexion occurred as soon as the mischief reached the joint, but so long as the interior of the bone alone was involved it did not occur; this corresponded with the "latent period" so often seen, and was confirmatory of the view that the bone lesion is primary. The proportion of cases excised to those seen was about one in six. There was no reason to suppose that the excised cases differed in pathology, but only in the stage at which they were seen and in the possibility of carrying out efficient treatment.

Reviews and Notices of Books.

A New Departure in Science. Being a Second Edition of a New Chapter in the Story of Nature. By CHARLES BLAND RADCLIFFE, M.D. 8vo. London: Macmillan and Co. 1886.

NOT the least important aid to one branch of science is often furnished by those professionally engaged in another department, for the wider the sphere of a man's knowledge so much the more philosophic will be his treatment of special subjects. Thus geology owes much to the labours of surgeons and physicians, among whom may be mentioned Fitton, Mantell, Dixon, Holl, Lycett, Duncan, and others; and during the past seventy years no less than six medical men have occupied the presidential chair of the Geological Society of London. Of these, Mr. J. Whitaker Hulke (formerly president) has just been awarded the Wollaston Gold Medal, the highest honour the Society can bestow, for his researches on Fossil Reptilia. Now and again, however, a feeling of scepticism in scientific teachings is developed in the minds of those who pin their faith on the literal interpretation of the Bible; and this is especially prominent if they have some acquaintance with geological literature, but have failed to thoroughly grasp the principles of the science. The results when put in print are generally lamentable, and unfortunately we cannot make the volume under notice an exception.

The author's first "departure" is founded on his belief that there is a tidal wave in the land, dependent upon tidal fluctuations in subterranean heat. His conclusions are based on barometrical observations taken at high and low water, afloat and on shore, although he previously "saw that the atmospheric pressure must increase if the land or water went down, and decrease in the contrary case." His observations show a slightly diminished atmospheric pressure ashore at low water, but no material difference between the pressure afloat and on shore at high water. The records, however, are somewhat conflicting, nor is any statement made of the temperature at the different places. It is well known that there are areas of high and low pressure distributed side by side, and meteoric

Digitized by Google

influences would be amply sufficient to account for the slight differences recorded by the author, while in any case the records are too meagre for the establishment of general conclusions on the subject. It is true he admits that "no doubt additional evidence is wanted before it is possible to lay down the law positively," but further on he adds, "and to return, it may not be wrong to conclude that the evidence in favour of a tidal wave in the land is even more conclusive than the evidence of a tidal wave in the water." Throughout his volume the author, after introducing his new departures and pointing out that it may be so and so, has a tendency to argue as if it *is* so, and as if his statements and conclusions might be accepted as facts. He seldom presents any real arguments against these "departures," and appears to read too much in the light of his preconceived opinions. In the case of the tides, no doubt, it is difficult to define the exact influences that affect them, through the revolution of the earth, the configuration of the coast lines and of the ocean beds, and from astronomical causes. The author, however, says little about the action of the tides on rivers, nor does he point out how they would be affected by upheaval of the land. It is well known that minute earth tremors affect the land—vibrations (almost microscopic in character) that are produced both naturally and artificially, and in the former case sometimes by variations in barometric pressure. Nevertheless, in the case of violent earthquakes the vertical movement of the land is seldom more than one millimetre, and yet from the observations of the author at Eastbourne he found, to his great delight, "that the *land* went down at high water and up at low water, and that this movement amounted fully to nine feet"!

That rocks may expand under the influence of heat will not be denied, but we cannot follow the author further when, for example, he remarks "that some rocks expand and shrink more than others under the action of tidal fluctuations in subterranean heat, and that a day may come in which the rising and falling of the tidal wave may give the key to the geological construction of the sea-board—when, e.g., an exceptionally high tide may be looked upon as pointing possibly to the presence of coal at no great distance from the sea in that locality."

Dr. Radcliffe's second "departure" is one "in which subterranean and other forms of natural heat are found to be dependent upon electrical incandescence, &c." He observes: "The simple fact is that the earth is traversed instantaneously by electrical currents from the sun and moon; that these currents in certain parts of their course across the earth are, as instantaneously, frittered down into heat by resistance." In this way he would account for the temperature of the Bath waters; but we must pass over the laboured arguments which are put forth to interpret facts that are capable of simple and intelligible explanation on the theory of the earth's internal heat. Although the author is apparently acquainted with the fact that the daily changes of temperature do not affect our soil beyond a depth of about three feet, and that the annual variation below twenty-five feet is very small, yet he does not realise that the subject of the gradual increase of temperature at greater depths is incapable of explanation in the way he supposes. The temperature of the earth's surface varies according to the heat of the sun, whereas in descending below the surface to a depth of upwards of fifty feet, we reach a point where the oscillations of temperature due to surface causes cease; we come, in fact, to what is termed "the stratum of invariable temperature";[1] and below this, wherever observations have been made, the temperature gradually increases.

Turning to the concluding "departures" of the author, we are not surprised to learn that he is incapable of accepting the doctrine of evolution. He states, as one departure, that "in which the age of the earth is not found to reach very far back into immemorial times." Sir William Thomson has pointed out that the period during which life can have existed on the earth's surface should perhaps be restricted to about 100,000,000 years, and Dr. Croll has inferred that the glacial period probably commenced about 200,000 years ago. These figures may be fairly approximate, but they do not profess to be precise, and we should not find so much fault with the present author if his conclusions rested upon facts. He says: "A chief reason for believing in the extreme antiquity of the fossiliferous rocks is that which is supplied by the doctrine of evolution. Set aside this doctrine, and the reasons for entertaining a view altogether different to it retain all their force. So it may be—nay, so it must be. And if so, then there is so far nothing in the history of the fossiliferous rocks to make it absolutely certain that immemorial ages have been spent in the formation of these rocks." The antiquity of the earth is proved by the succession of sedimentary deposits and the succession of more or less distinct faunas and floras in different areas, as well as by the evidence of breaks or intervals that were accompanied by upheaval of the strata and extensive denudation. Continuous deposition was no doubt going on when we take in consideration the entire area of the earth's surface, but many physical changes have interrupted this continuity locally. In the same way the chain of organised beings was no doubt continuous, when we consider the life history of the earth's surface as a whole; and one of the charms of geology is to be able to discern in the strata of a small area like England evidences of physical conditions that are repeated in various climes and conditions over the globe at the present day.

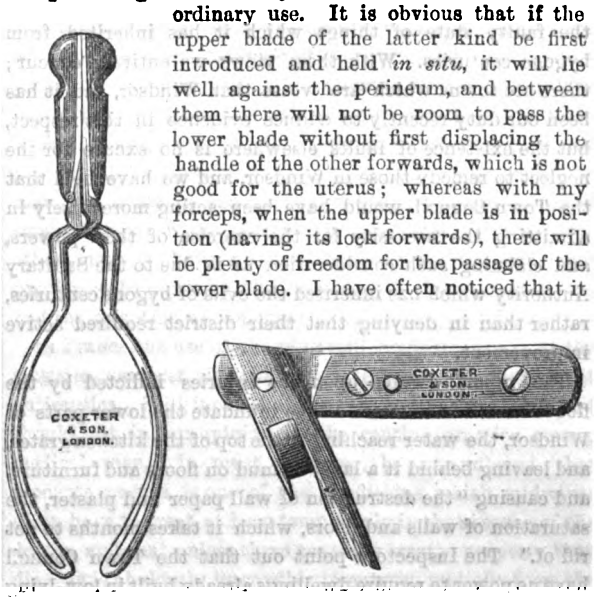
The final "departure" of the author consists in the assertion that "the actual and Scriptural history of the earth are found to be not wholly irreconcilable," and that "the elder stratified rocks were formed in the comparatively short interval between the creation and the deluge." He speaks as if the series of stratified rocks was formed continuously, observing "how in the space of a year the great revolution in which the bed of the ancient sea was converted into the present land may have been brought about." The "universal deluge" in his opinion preceded the glacial period, and was due to the refrigeration, because "with water everywhere the earth would be insupportably cold." We have at present no positive evidence of human remains in pre-glacial times, but man no doubt occupied portions of the British area during the glacial period, for the old flint implements found in the Thames valley deposits and in certain caverns are associated with a fauna that is older than some of the latest glacial deposits of the north of England. The idea, however, of a universal deluge is so entirely opposed by the present geographical distribution of animals that no one can hold it without at the same time believing in numerous special creations of different forms of life on the isolated continental areas and islands; while, as regards the antiquity of man, it has been remarked that if all the leading varieties of the human family sprang originally from a single pair a much greater lapse of time was required for the slow and gradual formation of such races as the Caucasian, Mongolian, and Negro than was embraced in any of the popular systems of chronology.

In noticing these "departures" of the author, we have quoted his own words in order to express his views as fairly as possible; but we cannot escape the conviction that in most cases he has gone out of the way to seek a new explanation of well-known phenomena, and his work is in reality a departure *from* science. No one believing in an all-powerful Creator would deny that anything might have been produced in any way; but the object of scientific in-

[1] See Green's Physical Geology, 3rd edit., p. 643.

Digitized by Google

vestigation is rather to ascertain in what way Nature has worked. In the one case observation and reason are the chief guides, and in the other we seek to interpret blindfolded. To many of us the geological record reveals a wonderful and beautiful story of the creation, and if so we may believe that our ability to decipher some portions of the history was likewise intended. Be this as it may, any attempt to reconcile literally the Biblical account of the creation with the geological record is about as scientific as as it would be to reintroduce the systems of surgery and medicine that were in vogue at the time the "Mosaic" account was written.



An Elementary Text-book of British Fungi. Illustrated by 64 Plates. By WM. DELISLE HAY, F.R.G.S. Pp. 238. London: Swann Sonnenschein, Lowrey, and Co. 1887.

As the poet says of vice, that we "first endure, then pity, then embrace," so it would appear from the writings of all professed fungologists, that we first suspect, then collect, then enjoy these singular half-animal, half-vegetable bodies. It is certain that by neglecting them and their culture a very considerable quantity of wholesome and eminently nutritious food is annually wasted; and it is not a little curious that, while most of even the smaller and less conspicuous flowering plants have received common names and are easily distinguished by field labourers, the very large group of fungi are only differentiated by the majority of even well-educated people into two groups—"mushrooms," or edible fungi, and "toadstools," or poisonous fungi, the latter including all but the three or four species of agarics that are found in open pastures. Mr. Hay remarks that no other nation is so ignorant, but that, on the contrary, the various peoples of the continent of Europe bestow a great deal of attention on fungi. He follows the classification of Fries, and refers for illustrations to the admirable work of Mr. Cooke which is now approaching completion. The neglect of fungi, of which Mr. Hay complains, is doubtless due to the difficulty of discriminating wholesome from unwholesome species, and he very rightly devotes successive chapters to their structural anatomy and the characters of the more common edible species. We give an extract which will show the lively style in which Mr. Hay writes, and the delicate food that is provided for us without cost were we only sure of true selection. Speaking of the Chantarelles, he observes: "Few mushrooms can be so readily recognised as this, and once known it is impossible to mistake any other for it. The chantarelle grows in woodlands and parks, and its distinguishing features are these: an irregular shape; gills like wrinkled folds or plaits; a uniform bright golden-yellow colour; a scent like that of plums or apricots. It is a supremely excellent viand, in high estimation among mushroom epicures. In continental markets it fetches a high price, though plentiful there as here. Finding it often in quantities near London, the author has sometimes presented basketfuls to his French and German friends in the metropolis to their great gratification. But when he has proffered it to his own countrymen he has usually encountered contemptuous scorn; so deep is the fungophobic superstition." Other excellent but entirely neglected mushrooms are the oreads—Marasmius oreades, which is the chief former of "fairy-rings"; the Blewit, Lepista personata, which the author declares is as good as veal cutlet; the Puffballs (Bovistæ), which, however, must be eaten when young, white throughout, and solid; the Helvels, the Mousseron (Agaricus prunulus), the Oyster (Agaricus ostreatus), and many besides. Mr. Hay is not content with describing the British fungi, and with indicating their economic value and digestibility, but he devotes a chapter to culinary receipts, which give the results of his experience in dressing them in a palatable manner for the table.

New Inventions.

MODIFICATION OF MIDWIFERY FORCEPS.

I BELIEVE it is a recognised fact that the chief difficulty, if it can be counted as such, in the use of the forceps lies in the introduction of the upper blade, for these reasons: When the lower blade is introduced first, it is an obstacle to the application of the upper one, from its presence in the vagina and by the uterine contractions which are set up dynamically by it. It is easier to introduce the lower blade chiefly on account of the relative positions of the patient and the operator; for on whichever side the patient may lie, it will be found to be more convenient for the hand to trace out the under surface of the fœtal head than the upper. However, a great authority says: "If we use the curved forceps—i.e., with the second pelvic or sacral curve,—then the *upper blade* is generally the *best* to introduce first." After this I take it for granted that, whether the upper blade be introduced first or last, it is always the more difficult to apply. In order to obviate this difficulty, Mr. Coxeter has constructed for me a pair of forceps having the lock adjustment reversed to those in ordinary use. It is obvious that if the upper blade of the latter kind be first introduced and held *in situ*, it will lie well against the perineum, and between them there will not be room to pass the lower blade without first displacing the handle of the other forwards, which is not good for the uterus; whereas with my forceps, when the upper blade is in position (having its lock forwards), there will be plenty of freedom for the passage of the lower blade. I have often noticed that it

is not so much the actual use of the forceps that alarms the patients as the preparation for the simple operation. "Drawing the patient to the edge of the bed and baring the buttocks" is not a pleasant procedure, but hitherto a necessary one on account of the rigid blade. In these instruments I have endeavoured to obviate this also; for in the handle of the upper blade adjoining the lock there is a lateral hinge which flexes backwards, but which is rigid to forward pressure; when closed, it moves on two plates, with a concealed pivot constructed in such a way as not to impair the strength of the blade for leverage or traction; neither is it conspicuous when the handles and locks are in apposition. The shanks are made sufficiently open to admit the index-finger comfortably for traction, and the handles are full long. When the handle is flexed, the upper blade is shortened, and can be introduced without altering the position of the patient, supposing she is in the usual obstetric position. The upper blade being passed, the lower easily follows. The forceps have also been fitted with Dr. Aveling's handles, the curve of which greatly aids the design of the instrument.

THE LANCET.

LONDON: SATURDAY, MARCH 5, 1887.

THE Local Government Board have published the report upon the Sanitary Condition of New Windsor, which has been presented to them by their Inspectors, Dr. HUBERT AIRY and Mr. ARNOLD TAYLOR. We trust the lessons it teaches will be taken to heart by the local authority, whose members have until now denied the existence of conditions which have been the subject of special reports by our Sanitary Commissioner.

Windsor, the Inspectors state, is in most respects no worse, and in some respects is distinctly better, than many other old towns with which they are acquainted, and they think some allowance should be made for the difficulties that beset a sanitary authority in its endeavours to amend the faulty state of things which it has inherited from bygone centuries. With these views we entirely concur; there are towns which are worse than Windsor, and it has been our duty recently to adduce evidence in this respect, but the existence of faults elsewhere is no excuse for the neglect to remedy those in Windsor, and we have held that the Town Council would have been acting more wisely in admitting the necessity for the exercise of their powers, and claiming such consideration as is due to the Sanitary Authority which has inherited the evils of bygone centuries, rather than in denying that their district required active improvement.

The report dwells upon the injuries inflicted by the floods which from time to time inundate the lower parts of Windsor, the water reaching to the top of the kitchen grates, and leaving behind it a layer of mud on floors and furniture, and causing "the destruction of wall paper and plaster, the saturation of walls and floors, which it takes months to get rid of." The Inspectors point out that the Town Council have no power to require dwellings already built in low-lying situations to be altered in such a way as to raise their ground floor above the flood level, but they omit to discuss how far they might be expected to prevent the overflow of the river by work such as that which has been successfully carried out at Strood, on the banks of the Medway.

Apart from this, the Inspectors describe, in words of condemnation, the condition of the older courts and alleys of the town, where they find that, "though in many cases the houses stand on fairly sound ground, their condition in respect of outside air space, back-yard space, internal ventilation, closet accommodation, surface formation, and pavement—in some or all of these particulars—is still pitiably bad." Ample details are given in the body of the report from the Inspectors' own observation of the grounds upon which this general statement is based. Thus, in Garden-court, back yards, or rather closet-wells, are only from four to six feet across, and contain each a pan-closet to be flushed by hand; water has to be fetched from a stand-pipe near the entrance to the court. The absence of back windows in different parts is generally commented on. In Distil House Row it is noted, among other defects, that the houses have no back yards, while cavities in the ground receive ashes and house refuse, and "at the edge of the back lane which bounds these courts stand four pan-closets for thirteen houses, pans dirty for want of flush-water, woodwork giving way." Again, in South-place, "of thirteen houses on the south side, ten have no opening whatever at the back, no scullery, no closet, and no water, but a tap at the end of the row." For closet purposes, the sixty-five dwellers in the ten houses have to go into an open yard at the back of the opposite houses on the north side. Some houses in South-place wanting in ventilation, the Inspectors believe, can be remedied by putting in a window at the head of each stair; but as for the houses on the south side, they "see no way of rendering them tolerably habitable but by demolishing every third house and converting its site into a yard for its neighbours, with a proper water-closet to each." Keppel-row is referred to as "another insanitary locality," and a description of its condition is given; and the Inspectors state, they might add details concerning Keppel-street, Love-lane, and others, but that the examples they have cited will suffice to show the general condition of the older and poorer dwellings in these parts of Windsor.

Concerning the sewerage, the report observes that "the flushing is not sufficient to keep the long and almost level outfall sewer (with a fall of three feet in a mile) free from deposit, which thus is left in the sewer long enough to decompose and cause offensive effluvia from the gratings." House-drains are further condemned, the report asserting that "there is reason to believe that in many cases the house-drains are ill-laid and unventilated, and ready to convey poisonous gases direct from the sewer to the house through an untrapped sink-pipe or an ill-constructed watercloset." The Inspectors lament the insufficiency of the general law to do more than hinder the recurrence of those conditions which have actually shown themselves to be nuisances; the fact remains, however, and we have urged this with regard to Windsor, that the poor cannot be trusted to make complaints, and that nuisances, if they are to be remedied, must be sought for by the Sanitary Authority. The report also wisely points out that although the work of nuisance inspector is enough to demand a man's whole time, and the sanitary authority ought not to content themselves with less, this work has entirely devolved upon an officer who is the borough surveyor, the inspector of common lodging-houses, the inspector of weights and measures, of petroleum, and of canal boats. As the report states, without a proper staff no local authority can fully enforce the provisions of the Sanitary Acts, and Windsor is quoted as a borough which needs amendment in this particular. The fact is dwelt upon that most, if not all, of the courts and streets whose defective sanitary condition has been detailed might have been dealt with, externally at least, under the 150th and following sections of the Public Health Act, 1875, but no attempt appears to have been made to use these sections.

We note with pleasure that Dr. CASEY, the medical officer of health, is regarded by the inspectors as an able and conscientious officer, and that they find in his annual reports

Digitized by Google

evidence of much good work in his district, and sound advice offered to his Sanitary Authority. They state, however, that Dr. CASEY has under-estimated the importance of such sanitary defects as have been described in connexion with South-place, or else has over-estimated the difficulty of legally dealing with those defects.

As the result of their inquiry, the Inspectors recommend, where the Public Health Act, 1875, is insufficient, that resort should be had to the Artisans and Labourers' Dwellings Improvement Acts, 1875 and 1882, for the improvement of unhealthy areas; that there should be more constant and thorough nuisance inspection, and that a separate inspector of nuisances should be appointed for this purpose; and, finally, that the Sanitary Authority should make the much-needed provision for the isolation of infectious disease, for the disinfection of infected articles, and for the destruction of house refuse.

If these recommendations be faithfully carried out by the local authority, we shall certainly feel we have not laboured in vain. Already, as the result of publicity given in THE LANCET to sanitary neglect in Windsor, great improvements have been effected. We have no hesitation in saying that, notwithstanding the still unsatisfactory condition of many parts of the town, the Windsor which is the subject of the report of the Local Government Board is very different from the Windsor to which we first directed public attention in August, 1885. The extraordinary efforts made by the Sanitary Authority after the publication of our articles are well known to us through subsequent inspections of their town by our Commissioners. There is, indeed, no more instructive passage in the whole of the report of the Local Government Board which is now made public than the statement that, "in looking through the Nuisance Report Book, we could not fail to notice that in the single month of September, 1886" (the month before the Inspectors' visit), "there are about as many cases of premises inspected and nuisances reported as in the two years from September, 1884, to August, 1886."

IN resuming our discussion of the subject of placenta prævia, we come to some points in the history of that condition. Internal version requires dilatation of the cervix to an extent implying that labour has advanced to a considerable degree of progress. To wait for this is often impossible, and *accouchement forcé* (forced delivery) was formerly the only alternative.

The first great advance was made in 1860 by Dr. BRAXTON HICKS who showed the possibility of turning by the bipolar method when the cervix would admit two fingers, or even one. He expressly pointed out the advantages of early version by this method in placenta prævia, and published a series of cases to illustrate his point. Our Teutonic brethren seem to have read his publications (which are plain enough) without understanding, for the greatest German accoucheurs, VON HECKER and SPIEGELBERG, opposed and decried bipolar version, but showed that they failed to comprehend it. In the meanwhile various methods of treatment were proposed and partly adopted, and HICKS's method seems to have been practically unknown in France and America. Twenty-two years after its publication a serious trial of early bipolar version was made by HOFMEIER, a year later by BEHM, and a year later by LOMER, all in Berlin. It was then found that the method which an English accoucheur had described and practised in 1860 required twenty-two years and a foreigner to bring it into vogue.

These accoucheurs treated 236 cases with eight maternal deaths, a mortality of 3·3 per cent. BEHM delivered fifty-eight cases consecutively, without a single maternal death. It must be remarked that HOFMEIER and BEHM treated all their patients themselves, whereas LOMER'S cases were treated by nine different assistants. The presence of a skilled operator must of course be discounted in comparing ancient with modern methods, and so must the use of antiseptics. Still, it may be safely said that, after all due allowance is made, the above results have never been nearly reached. The reduction of mortality may be stated as from 24 per cent. to 3 per cent. The method may be described as—*a*. Bipolar podalic version as early as possible. *b*. Extraction by natural forces, or after complete spontaneous dilatation.

It is found, as said above, that the bleeding practically ceases after version and before extraction. As regards the life of the child, delay does not, according to statistics, much impair its chances, which are always bad; and, on the other hand, the great danger of laceration and fatal hæmorrhage from it is set aside, while a fertile source of sepsis is also avoided. Other methods are still mentioned in text-books: complete or partial separation of the placenta, rupture of the membranes, and plugging. Rupture of the membranes and evacuation of the liquor amnii is often impossible when the placenta is completely prævia; the other methods have no such brilliant results, and must predispose to sepsis by the fingering of the placental site, and the retention of clots near it which they entail.

In France the use of the plug still holds its own, and the statistics have certainly improved since the introduction of antiseptics. Still, it can show no results like the above, and should not, in our opinion, be the routine practice among medical men. It must, however, be remembered that placenta prævia is one of the conditions which midwives often have to treat, at least temporarily in the absence of the doctor, and that unless these cases are treated properly they die. It is obviously impossible to entrust midwives, on the other hand, with so delicate an operation as bipolar version. For midwives the best treatment will certainly be to plug tightly with antiseptic precautions, washing out the vagina, and plugging, if possible through a speculum, with cotton-wool or gauze rendered aseptic. There is nothing better for plugging than a bandage of corrosive sublimate gauze. The plug excites contractions, controls hæmorrhage to a considerable extent (for concealed hæmorrhage in placenta prævia is almost unknown), and preserves the membranes for turning by the accoucheur.

In summing up the question of treatment, it must be remembered that cases divide themselves into two principal classes: The first, in which the uterus, so to say, takes matters into its own hands and acts powerfully; in these cases, to temporise and assist labour, as by forceps or rupture of the membranes if they present, will often be sufficient. The second, in which the labour is disordered, the uterus demoralised, and, unless prompt and skilful help is at hand, the tendency is to rapid death. It is these cases, about which there should be no two minds with regard to treat-

Digitized by Google

ment, and it seems to be proved that it may be summed up as (*a*) bipolar version as early as possible, (*b*) extraction actually or practically left to nature.

There is yet a third class of cases—namely, that in which the patient is either moribund or in extreme and urgent peril from flooding, and in which forced delivery by manual dilatation affords the only chance. These cases are exceptional, and it is hardly necessary to add that the operation should be performed with all possible skill and gentleness.

There are several morals to be deduced from the history of placenta prævia. Firstly, the new is not always the true, nor the truth new. The latest improvement may be a retrograde movement, and the "greatest modern triumph" a thing of which the not remote future will be ashamed. We need not illustrate this maxim here; it is a text on which we have preached and shall preach again. To the reader we need only say, in the language of Sir CHRISTOPHER WREN'S epitaph (slightly altered) "Si documentum requiris, circumspice." The verdict of the day is often wrong; each must make up his mind as to what is bad and false and what is good and true. To follow fashion may entail forty (or twenty-two) years' wandering in the wilderness, till it takes a foreigner to conduct us into the promised land. Secondly, it seems possible that even the most intelligent foreigners may fail to understand plain English and decry a practice which they fail to comprehend. In this instance it took twenty-two years for them to comprehend it. Thirdly, English practice is not always the worst, even if unacceptable on the Continent.

It will be seen that the best modern practice agrees with Dr. BRAXTON HICKS'S recommendations in 1860, and that though some of the facts in the pathology of placenta prævia (such as the arrest of hæmorrhage after turning and before extraction) were unknown to him at that time, as well as to his contemporaries, his name deserves a prominent place in the history of the affection.

IT is important to study the charges made against members of our profession. They are bound in the very nature of their calling to place themselves often in difficult positions which can easily be misrepresented by little or unfriendly minds. Sometimes unreasonable duties are required of them and unfounded charges are brought against them. It is true that as soon as they get into an open Court and can challenge the judgment of a trained judge or an intelligent jury, their adversaries are generally discomfited and the case against them melts into very thin air; but, nevertheless, great injury is done to them, and no redress that law can give can repay them for the injury which law permits, and which perhaps it is not in the power of law to prevent. We have reports of two or three cases which painfully illustrate the injury which the law allows to be done to medical men even in cases where it vindicates their conduct and their honour.

In one case reported the doctor's name is not given, and he is very deeply involved. A working man, described as "respectable-looking," appeared before the Southwark police magistrate, Mr. HOSACK, to ask advice and assistance in the following circumstances. Three of his children were ill. One was affected in the thigh, another in the shoulder, and a third in the eye. He could not afford to pay for a medical man, and he sought Mr. HOSACK'S assistance to compel "the doctor to attend." The man was very much disappointed when told by Mr. HOSACK that he could not in any way help him. Probably the least respectable quality about this poor man was his intelligence. He seems to have mixed up very doubtful theories of his children's illness with equally absurd theories of the power of magistrates to compel medical attendance for nothing. His idea was that the children were suffering from small-pox brought through the doctor from children in an adjoining room. This individual's views of diagnosis are probably on a par with his legal views of medical duty, and need not detain us.

A more serious illustration of our complaint is to be found in the report of a case in the newspapers of Saturday last, in which a respected medical man, Mr. JOHN BROWN, of Battersea, appears as one of two co-respondents in a divorce case, the petitioner being Mr. JOSEPH CECIL LENNARD, a provision merchant. Mr. BROWN had an easy task in repelling the charges brought against him. He had been in frequent attendance on Mrs. LENNARD, whose father and mother he had known from the time of her childhood. He produced his books and a specimen of the very few letters he used to receive from her, which was of the most ordinary character, requesting him to call and see the little girl. He positively swore that he never had been guilty of any misconduct or familiarity with the lady. The accusation was made after Mr. BROWN'S account was sent in. Mrs. BROWN gave evidence for her husband, and said there never had been any secrecy about Mrs. LENNARD'S visits or notes to her husband. Sir JAMES HANNEN'S remarks were very good. He said he did not know anything more important or serious than the question whether or not a doctor had been guilty of misconduct with one of his patients. Though such misconduct is a serious offence, it was for the welfare of society and of the medical profession that the freedom which was allowed the profession should not be made the basis of accusations unless established by the clearest evidence. In this case there was no evidence of the slightest familiarity between Mr. BROWN and Mrs. LENNARD, and the jury, without retiring, negatived the allegation against Mr. BROWN, and the petition against him was dismissed with costs. This is the sort of case which harasses a medical man grievously, and to which every practitioner is daily liable at the hands of unprincipled or ungrateful people. It may be said the judgment is all right; costs are allowed, and no harm is done. But what costs—even if they are forthcoming—can repay a practitioner for the annoyance extending over months, of an unfounded charge like this? And if they are not forthcoming, what grievous pecuniary injury is added to mental torture. We admit cheerfully the disposition of judges and juries to protect the fair fame of medical men, and to recognise the delicacy of their position and their reputation. But something is still wanting for their protection against wanton and unreasonable patients. It is not enough that they should be acquitted of such charges. They should not be placed upon their trial without some *primâ facie* case against them other than appears in a case like the one on which we are commenting.

Yet another instance. Last week an action was brought
